The third need to met for the structure is largely connected to the LCA-inventory practice. It holds components of assistance of such LCA issues as keeping system boundaries, and quality of inventory data. The demands that had to be fulfilled were: not be redundant, be consistent, be easy to update, easy to use in the inventory process when ever needed and be independent of the goal of the study.

The redundancy and consistency parts are aspects of the same inventory topic; LCA-data for a specific production process that is used as input-data in the inventory

of more complex products several times in the analysis ought not be stored in the data structure more than once. There are several reasons for this. LCA-inventory data for, for example concrete, may be used as input-data for the inventory of more complex concrete products. If the data set[1] for concrete is copied and integrated with the data for the complex products and at a later stage of the inventory work, the data set for concrete was found to be incomplete; then updating the data set becomes a time consuming task that might lead to an inconsistent representation of the environmental impact of the production of concrete if one or more processes has been forgotten. This situation creates data that is redundant which even might be inconsistent for the environmental impact of. the production processes studied. By storing the data set once and link it to the data set of more complex products, redundancy will not occur and the data will be consistent through out the entire structure. By thoroughly considering the system boundaries for the inventory of a production process and comparing the boundaries chosen to the general system boundaries of the study and by storing the data as a single unit[2] data set, the general system boundaries will be kept consistently as well.

By storing data in single units and linking the data set, the procedure of altering the data set (for higher accuracy, sensitivity analysis or improvements of production process etc.) becomes a less time consuming task. Another aspect of storing data in single units is that the data set becomes relatively independent[3] of the goal of the study. The reason being that the data set is not integrated with inventory information for other

[1] A *data set* is a table over the environmental impact that is duo to a specific production process. The table usually contains quantitative data for the energy and raw material use, emissions to air, water and ground per arbitrary pre-defined functional unit.

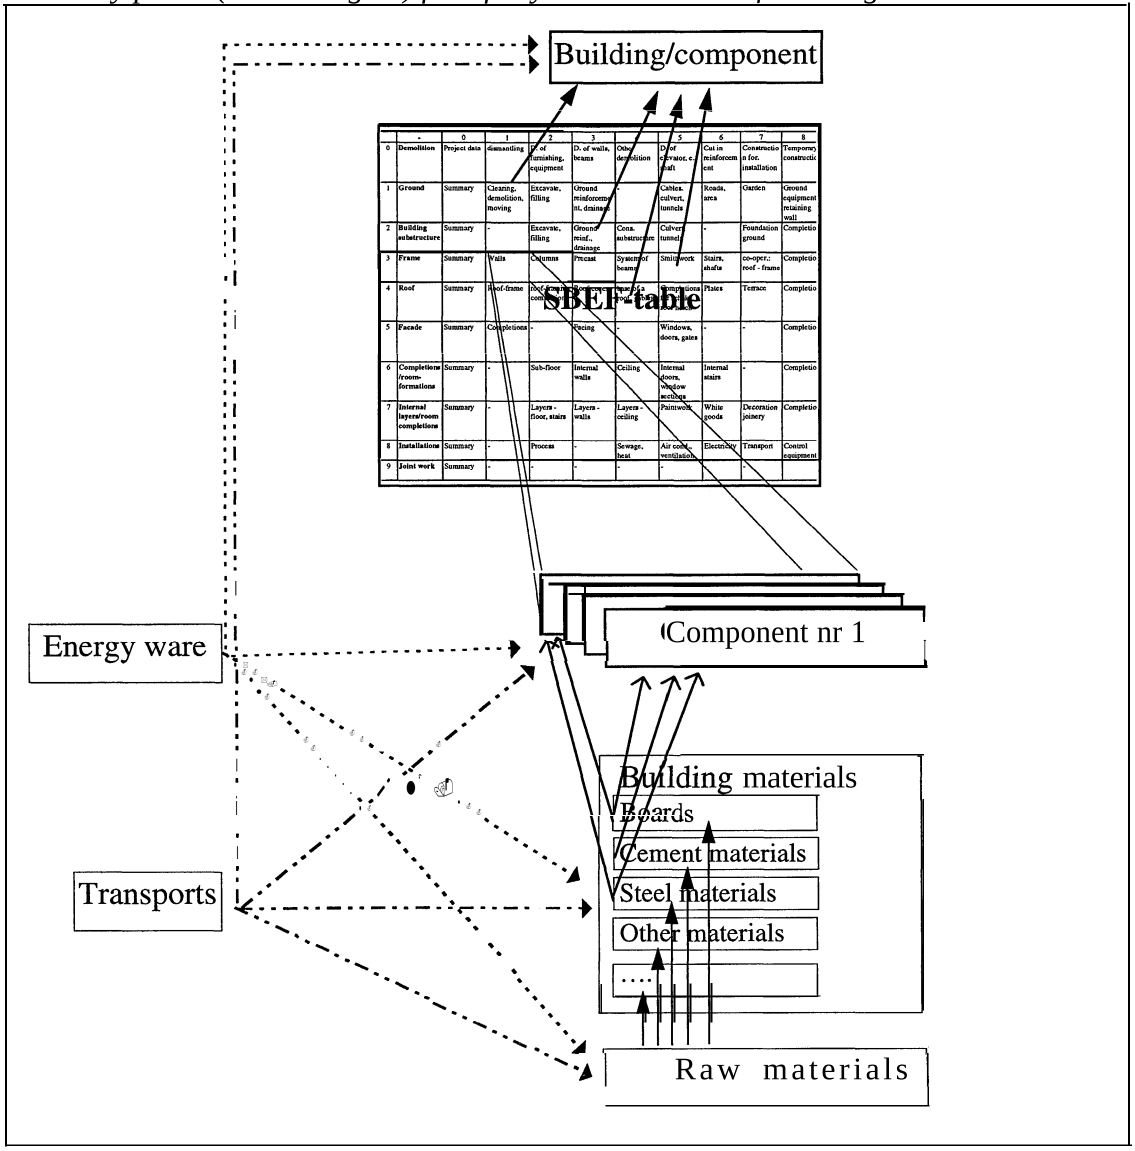
[2] The meaning of a *single unit* is that a data set is stored in the database once.

[3] LCA-data for a production process which has been subjected to allocation is not independent of the goal and scope of an LCA-study.

products[4]. Consequently, the data set may be reused in studies with similar goals and objectives. This will make the representation of data a strategic one, which over time, will generate more available LCA-data for the building industry at large.

The complete data structure that organizes the inventory data for the first inventory phase (cradle to gate) for life cycle analysis of buildings is presented in figure 3 . Here structural components for LCA-data of modes of transportation and energy wares have been introduced. These types of data sets were handled as general data that were available anywhere in the inventory when no other more specific (measured or site specific values of transport and energy related emissions to air water and ground) data were available.

Figure 3 The complete data structure that organizes the inventory data for the first inventory phase (cradle to gate) for life-cycle assessment of buildings.



---

[4] This statement i related to a certain view of the use of materials and products. In this case, it is the usefulness of materials and products for the building industry, hence the LCA-data becomes independent of the goal of the study for studies performed within the building industry.

3.1.3 Comparison of the implantation of the data structure in two analysis tools

Easy update and consistent representation of data sets in the structure as well as possibility to expand the structure were important LCA-issues for the data structure for the studies. These features heavily depended on the analysis tool to support the feature to link the contents of a data set in to another data set, as in the SPINE-Ecolab software. This feature was not supported by the LCAiT-software. It made this tool less suitable for the needs that had to be fulfilled to get the proper use of the structure. However, if the only question stated in the case studies was to assess the environmental impact of the frames, the LCAiT tool would have been suitable for the task regarding straight forward inventory calculations.

4 Hot spot analysis and the use of the data structure and analysis tool

The data structure proved to be quite useful when drawing conclusions in the second case study [3], were three dwelling and warehouse frames respectively were analyzed. In the impact assessment of the production phase, three assessment methods were used (the EPS- (EPS), Environmental Theme- (ET), and Ecoscarcity-method (ECO)) to find where the hot spots of the production phase were located. This question was raised in the earlier study [2] but was not answerable within reasonable frame of time and money. Due to a favorable combination of computerized analysis tool and the data structure, this question was easily answered in the second case study. The hot spot results are present in table 1.

Table 1 Table over how three assessment methods have spotted environmentally significant production processes in the production phase for precast-, in situ concrete and wooden frames [3].

Frame	EPS	ET	ECO
Precast frame	Cement	Reinforcement steel	Cement, reinforcement steel
In situ concrete frame	Cement	Reinforcement steel, cement	Cement, reinforcement steel
Wooden frame	Oil, plaster-boards	Decibel 2, plasterboard	Plasterboard

This hot spot analysis were empowered by the data structure, linked data sets and the assessment engine provided in the Ecolab analysis tool. In turn, the SPINE structure granted the feature of linking the contents of the data sets. If, for each frame, the data would have been aggregated, this analysis would have been quite time consuming and difficult to perform, as in the first case study [2] were the analysis tool did not provide feature of linking data sets.

5 Discussion and conclusions

Generally, the data structure presented in this paper tries to cover the information presentation problem by organizing the inventory data for the production phase in a, to the building industry, customary fashion. It also tries to support the system boundary keeping issue of the inventory work by leaning on a computerized database technique permitting and supporting linking of data sets for the production processes. The view of the building as a material system is however limited. The data structure is designed for the environmental assessment of building materials in a functional context of the building material producing industry. To achieve this goal, the view of the building as a system had to be set to the one of the production phase were building materials are assembled to functional products. It might be put forward that what you get is, at the best, what you have designed and planed for, i.e. saying that the design phase is very important for the over all performance of a building. However, Swedish environmental studies [2], [3], [6] shows the service life phase to have the largest environmental impact of the three phases of the life-cycle of a building over 50 years; especially the environmental impact of the providing of heating energy used during the service life. The structure presented are mainly concerned with the data for the environmental impact of the materials used in the building in the production phase. In a larger context, this is perhaps of a more limited interest, with the assumption that the present technique of providing energy wares will be the same in the future. If assuming a change in this system (towards lower impact), the impact of material production will become a relatively higher compared to the providing of energy wares. Therefore, a development towards supply of heating energy with lower environmental impact will redirect the environmental attention towards the material production phase.

Acknowledgments

The development of the issues presented in this paper are based on the LCA-case studies of building frames which were financed by Scansem and the Nordic council of ministers.

Energy Implications of the Transportation of Building Materials

A. J. Miller
Department of Construction, Geography and Surveying
University of Brighton
UK

Abstract

The embodied energy is a significant factor in the whole life energy consumption of a building. Its proportion of the total energy consumption attributable to a building throughout its life is increasing as improvements in thermal performance and energy efficiency of systems reduce the energy consumption during the occupied phase of the building life.

The embodied energy can include all energy attributed to a building material from its original source through to construction on site. This paper considers the component of embodied energy that is attributable to the transportation of the materials. It is based on a case study undertaken of a single construction site, determining the energy consumed in transporting the construction materials to site. The results of this study are based on the energy consumed in delivery only, the fuel consumed for a one way delivery journey.

Literature search identified that common assumptions made by different researchers when evaluating transportation by road vary between 1.18 – 4.5 MJ/tonne/km. However these figures are assumed to include allowances for other aspects of the energy consumed that can be attributed to transportation such as return journeys and. the manufacture and maintenance of vehicles and roads.

The paper shows that for a particular study of a site in Brighton 1.5% of the total embodied energy was attributed to the energy consumed in the delivery of the materials.
Part load delivery and packing ratio are identified as factors affecting the energy consumed in transportation of materials and these issues are discussed with reference to the Brighton case study.
Keywords: Embodied Energy, Transportation

1.0 Introduction

The life cycle of a building commences with the winning of the raw materials that are usedto produce building materials and components and ends with the final disposal of those materials after demolition of the building and the re-use or recycling of suitable products. It includes all of the stages of construction, operation and demolition as depicted in fig. 1.

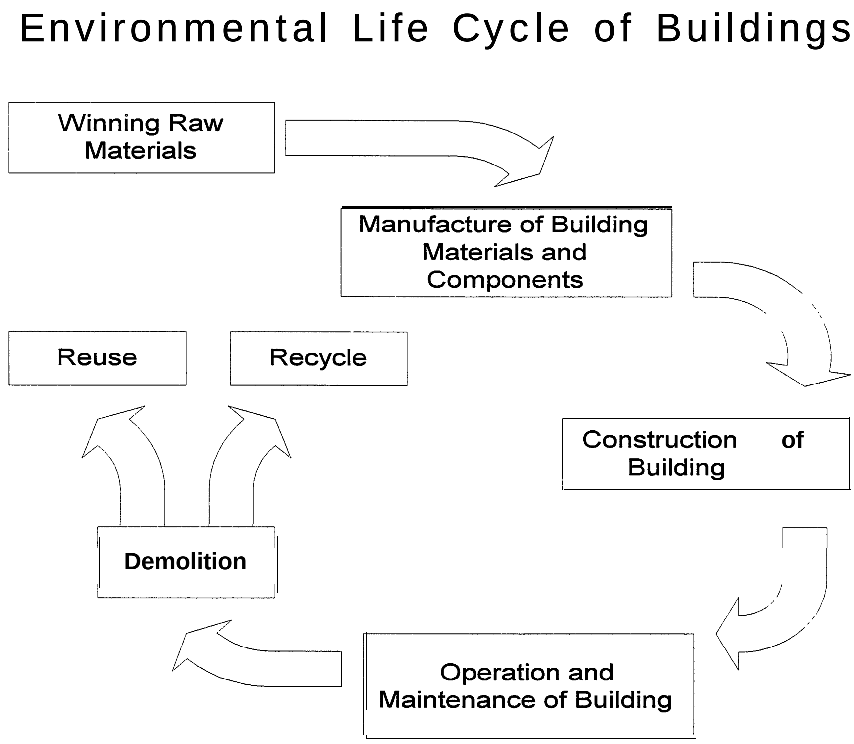

Fig. 1 Environmental Lifecycle of Buildings

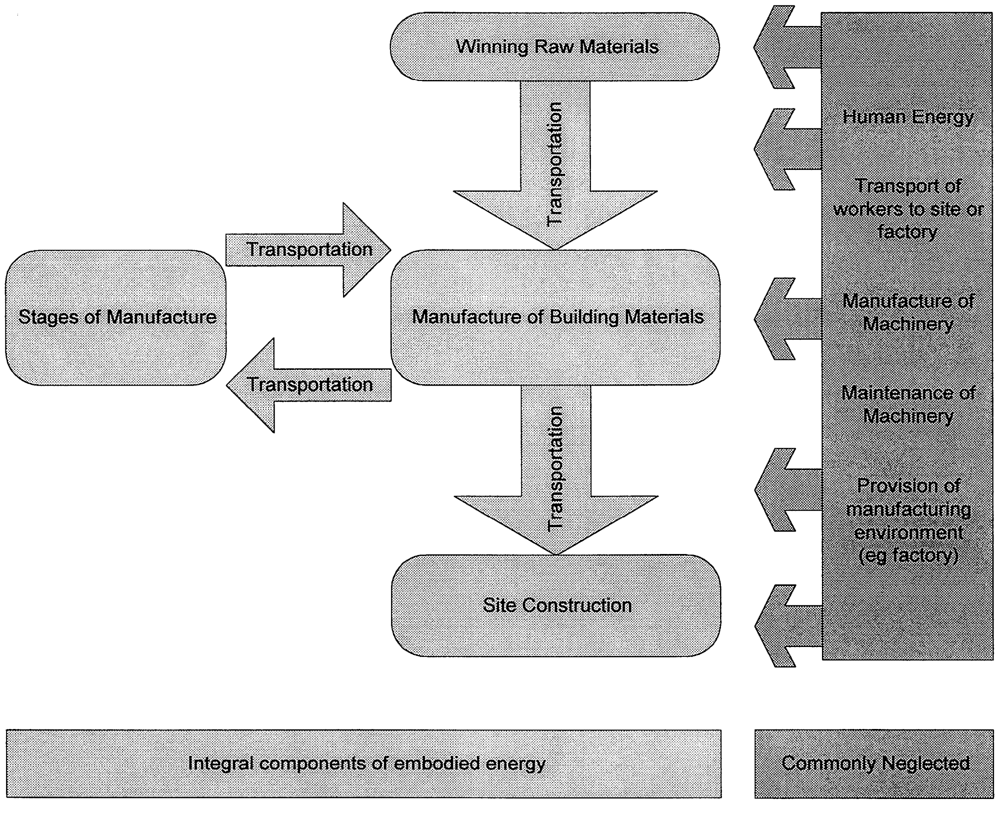
Throughout its life cycle a building will consume energy, generally in the form of fossil fuels. The consumption of fossil fuels results in the depletion of natural resources and in the production of pollution with its subsequent problems such as global warming and acid rain. It is estimated that more than 50% of UK energy consumption can be attributed to buildings and a similar proportion of the carbon dioxide emissions.

Much research has been aimed at understanding the energy consumption of occupied buildings and at reducing that consumption. However it is estimated that the delivered energy embodied in the constituent building materials and components is 350 PJ per annum (equivalent to 20% of the annual energy consumption in the UK domestic sector) and is responsible for 8% of the national carbon dioxide emissions. (1)

This paper is based on research undertaken at the University of Brighton aimed at improving our knowledge of the total embodied energy of building materials. In particular it studies the component of the embodied energy that is attributable to the transportation of those materials. The research project was sponsored by the Engineering and Physical Sciences Research Council.

2.0 Embodied Energy

The embodied energy of a building material or component is the total energy consumed in winning the raw materials, manufacturing the components and constructing the building on site. It includes the energy consumed for transportation within and between each of the stages leading to the completed building as shown in fig.2.



.Fig. 2 Components of Embodied Energy of a Building

2.1 Boundaries

A full audit of the embodied energy of any item can be very complex and there are diminishing returns with respect to the accuracy of the calculation the further removed the analysis becomes from the item under consideration. As a result the evaluation is often simplified and Fig.2 presents a commonly accepted definition of the embodied energy of a building.

Calculated in this way embodied energy figures are clearly site specific. They are related to the specific materials, suppliers and efficiency of distribution and delivery route. There is however generally no need for such a precise figure to be determined in order to provide useful data for building designers.

Published embodied energy figures for common building materials vary enormously and there is often little indication of what has been included in the analysis or how they have been obtained. Common exclusions are shown down the right hand side of Fig.2 but the transportation component is also often omitted or considered using gross simplifications.

3.0 Transportation Energy

This paper focuses on the energy consumed in transporting building materials from their origin to the building site and highlights a wide variation for different materials.

It is appreciated that the transportation component of embodied energy is often small compared to the total embodied energy of a material, but investigations have shown that in general, oversimplifications are made when estimating this component.

It is common practice to estimate transportation energy embodied in building materials through the use of a standard consumption in MJ/tonne/km.

Estimations of energy consumed in the transportation of building materials vary considerably and table 1, based on an original by Lawson (2), presents published figures for estimates used in Canada, Denmark, the UK and the USA. There is however no indication of the basis on which these figures were determined and comparisons are therefore dangerous.

Road Vehicles		
Country	MJ/tonne/km	Reference
Canada	1.18	(3)
Denmark	1.44	(4)
UK	4.50	(1)
USA	2.13	(5)

Table 1. Published figures for vehicle transportation energy

The research undertaken at Brighton has focussed on the delivery of materials to a single building site situated on the Brighton seafront and full details of the measurements have been published elsewhere (6). Vehicle fuel consumptions were calculated based the consumption of diesel with a calorific value of 35.7 MJ / 1 and vehicle efficiencies were based on the miles per gallon figures published in Philips (7).

A summary of the results of this study is given in table 2. The energy consumption figures are an order of magnitude lower than the estimates shown in table 1, however they represent only the energy consumed in the process of delivery and not the total amount of energy that can be attributed to the transportation of the materials.

Material	MJ/tonne/km	Material	MJ/tonne/km
RMC Concrete	0.10	Chipboard Flooring	0.29
RMC Mortars	0.05	Plasterboard	0.24
Dense Concrete Blocks	0.02	External Plaster	0.62
High Density Blocks	0.09	Internal Plaster	0.48
Thermal Blocks	0.05	Windows	0.33
Concrete lintels	0.72	Roof Slates	2.55
Structural Steel Beams	0.08	Celtex Insulation	7.92
Steel Shuttering	0.16	Angle Ties	49.24
Concrete Reinforcement	0.36	Zinc phosphate paint	1.34
Roofing timber	0.15		

Figures estimating the total energy consumed in transportation would include:

- fuel consumption in the delivery of materials
- fuel consumption in the return journey of the delivery vehicle
- attributable proportion of the energy consumed in the manufacture and maintenance of the vehicles

- attributable proportion of the energy consumed in the construction and maintenance of the roads

The components found to consume the most energy in transportation in the Brighton study were the steel beams, accounting for 18% of the total energy consumed in transportation. The steel shuttering and the ready mixed concrete were the other major proportions of the transportation energy, each representing approximately 11% of the total. It has been shown that these figures, based on consumption for delivery only, represent approximately 1.5% of the total embodied energy of the materials, when related to an average of published embodied energy figures.

4.0 Identification of Key Issues

Analysis of the results identifies that the delivered quantity of materials and the relationship to the maximum payload of the delivery vehicles are important factors in determining the energy consumed in transportation.

Vehicles may not be carrying their full payload capacity for a number of reasons and these are considered further under the headings of part load and packing ratio.

Part Load

A construction site may have received part load deliveries because:-

- The total site requirements are for less than a full load and the manufacturer or haulage company cannot schedule a full load.

An example of this can be seen in the delivery of angle ties of which only 0.1 tonnes were required on the site. These were delivered as a single load in a 4.5 tonne truck over a distance of 369 km.

There are of course a number of reasons why some deliveries need to be made in this way, but the relative energy cost is high. Careful planning of ordering schedules from the site and delivery schedules from the supplier would reduce this component.

- The restrictions on site storage are such that the total requirements for a material cannot be ordered at one time resulting in part load orders.

This problem was experienced in the delivery of thermal blocks where the 3 14 tonnes required were delivered in 22 separate deliveries. On this occasion it was not caused by part loading individual vehicles as smaller vehicles were used, but naturally the overall distance travelled was far greater than it needed to be.

- Security on the site is such that sub-contractors are unwilling to order the full requirements for fear of theft.

Loose materials are generally the responsibility of the sub-contractor until built into the building. Valuable materials that can easily be removed from site are therefore often delivered in small quantities.

On this site the plaster for the building was delivered in 14 separate journeys, once again increasing the distance travelled. However in this case the fmal leg of the deliveries, from supplier to site, were also at only 65% of the possible payload.

These issues will be affected by the material's distribution network, the management of the transportation system and the site management. The ability to organise full load distribution will be affected by whether the transportation is being undertaken by a manufacturers supplying their own products or by a specialist haulage contractors who might have the opportunity to plan a more efficient schedule for individual vehicles.

Packing Ratio

The nature of the building materials or components being transported dictate the type of vehicle being used which may result in the maximum load not being carried.

- The physical shape of the materials or components may make it impossible to load the vehicle to its maximum load.

The steel shuttering was a typical example of this effect as for each section of the journey the vehicles were only carrying approximately 25% of their payload capacity.

- The density of the material may be so low that it occupies a large volume.

The rigid insulation materials used on the site weighed a total of 1.1 tonnes but for the two legs of the journey travelled in a 25 tonne and 18 tonne vehicles.

These results do not identify inefficiencies in delivery but highlight limitations of the existing transportation system.

5.0 Conclusion

This project has resulted in the determination of transportation energy consumption figures for the full range of construction materials to a specific building site in Brighton. These figures are site specific and depend upon the specific set of circumstances relating to the building and its construction programme. The calculated transportation energy figures should therefore not be taken as transferable to any other construction site.

However the key factors raised by this study are widely applicable and their sensitivity need to be considered whenever embodied energy figures are evaluated.

The transportation energy calculated in this project, based on fuel consumption for delivery only, represents approximately 1.5% of the total embodied energy when published embodied energy figures are used. This figure will naturally increase when return journeys, vehicle manufacture and maintenance and the road network infrastructure are considered. Further, it relates to published embodied energy figures, which themselves vary by more than 100% in some instances. Nevertheless it serves as an indicator as to the significance of the transportation component for individual materials.

The key factors of part load and packing ratio have been analysed identifying common occurrences that make it impossible to optimise the efficiency of delivery. The more obvious factors of vehicle used, distance travelled and route taken, have also been considered and extenuating circumstances identified.

Ecological water reservoir

A.A. Hess and M.B. Natalini
Stability Department, Engineering College, Northest National University, Resistencia, Chaco, Argentina

Abstract
Due to the noxious consequences of asbestos fibres incorporated to the human body, and because this material is used in different industries including construction industry and specially drinking water supply as well as domiciliary reservoirs, a subsitute material has to be found for the construction of the tanks.

Bibliographical analysis is the used methodology to stablish asbestos risks on health, and experimentation for material study.

The best results are obtained on those mixtures with bagasse aggregated, but new mixtures will be studied.

It is known that Xvegetal fibres are used energetical consuption will be lower. On the other hand incorporating vegetal fibres which can be found in the region costs could decrease in relation to the ones traditionally used.
Keywords: water reservoir, cement asbestos, vegetal fibres.

1 Introduction

Many samples of fibre use exist in nature to reinforce weak and fragil matrix. Low density wood through a cellular polymer compacted to chips provide a composed material naturally reinforced.

The use of straw in construction of sun-dried bricks (adobe) and mug walls, horse's hair or sisal incorporated to gypsum have been known and used for many centuries.

Asbestos was probably the first inorganical fibre used as a reinforce in compound materials. It is known that it was used in Finland since 2500 b.c. to reinforce potter's art pieces. It is still used currently in the construction of different elements of daily use, such as domiciliary water reservoirs even when it noxiousness to human help has been confirmed.

At the Stability Department of Engineering College - UNNE - (Northest National University) several technological investigation have been performed over mortar and concrete with natural aggregates such as sawdust, rice skin, as well as sugar cane bagasse 1) and esparto grass.

In October, 1996 the first Meeting of Projects of Cience and Technology Precompetitivity for Development was performed at the Central Library of the Autonomous University of Queretaro, Mexico. During the Meeting an specialist of the Scientific Research Centre of Yucatan, Pedro Herrera Franco exposed that the natural fibres use in concrete working up for construction will decrease industry costs and that fibres that are unprofitable today like sugar cane bagasse could contribute material within international patterns.

Noxious and sometimes ominous consequences produced by asbestos fibres incorporated to the human being trough aspiration or ingestion are well known.

Asbestos use is very diffused in construction industry, acoustic products, brakes, clutches, insulating materials, ceiling and covering, etc. On the other hand most people inclose it daily, because water supply is made through water pipe lines constructed with cement-asbestos as well as domiciliary reservoirs (elevated tanks, and reservoirs). It is importand to find valid alternatives which can perform the same function, in order to diminish the risk for human health.

Asbestos fibres can be replaced for vegetal fibres duly treated.

2 Objetives

- Establish the relationship between asbestos incorporation in human beings and the risks for their health.
- Determine a mortar mixture and vegetal fibres for the construction of reservoirs that can replace the cement asbestos currently used.

3 Methodology

Analitic, experimental, and deductive methods will be used.

3.1 Bibliographical analysis

Study of preliminary bibliography.

Research and selection of the specific bibilography to carry on the project.

3.2 Laboratory essay

3.2.1 Dosage tests to determine the most competent compound for the stablished purpose. .

For this essay IRAM 1622 Norm was followed "Determination methods of compression and flexure resistances".

3.2.2 Physical mechanical tests: Compression, tensil stress and flexure over test tubes performed with different mixture.2)

3.3 Laboratory work

Analysis and procedure of the results, in order to determine the material properties.3)

4 Working material

4.1 Construction material for test tubes

- Cement
- Sand
- Fibres: bagasse (husk from Sacharus officinarum), esparto grass (Spartina argentinensis)
- Water
- Additives (if necessary)

4.2 Equipment

Machines and instrumental needed for confection and test of the test tubes

4.2.1 Tubes

- 4 cm x 4cm x 16cm test tubes were molded with 12 % of esparto grass in cement weight.
- And prismatic test tubes with a lenght of 80 cm and a transversal section of 10cm x 10cm with 10 % of bagasse in cement weight.4)

4.2.2 For small test tubes flexure essay a CIENTEC machine of 3000 kg was used. The big test tubes were tested to flexion with a SUZPECAR of 100 tn.

In compression essay of both types of test tubes and universal press AVERY of 100 tn was used.

5. Results

5.1 Asbestos, an environmental contaminant

Asbestos can be found in nature, incorporated to rocks as fibres, with same other extraneous elements. So after it is extracted it has to be purifyed. The operation consists in making a crushed without breaking the fibres, afterwards it is removed and then separated putting through it an air flowing that carry away the fibres and left heavy elements as remnant.5)

Asbestos is formed by several fibrous mineral composed by hydrated silicate. The most abundant elements are chrysolite, chrosydolite, auronite, for which reason are the most dangerous. It is from a chemical point of view and hydrated magnesic silicate that may contain iron, whether as iron oxid or calcium oxid combined.

In the word about 6 (six) million tons of these mineral are extracted from mines in a year.

A great number of people are exposed to the perjudicial consequences of inhalation or ingestion of asbestos fibres. Their incorporation to the human body can cause not only a diffuse interstitial fibrosis but most important a higher frequency in different kinds of cancer, mainly a broncogenic carcinoma and mesotelioma.

Just in the construction industry, and in shipyards 3 to 5 million workers are exposed.

It was shown that a 38 % of isolater installers group presented asbestosis, even when these workers were exposed to concentrations about 5 millons of asbestos particles in one feet cubic of air, which is considered as the limit value for those expositions.

On the other hand, it is perfectly confirmed the indirect exposition, as it is shown by mesoteliornas frequency in workers family. A population is also exposed to contamination by inhalation or ingestion, what was shown by the presence of asbestos fibres in lungs of about 20 to 50 % of big cities residents in later autopsy.

The appareance of the disease after the exposure is variable. It could be brief, one or two years, but generally the symptoms take much more about 10 or 20 years to come up.

Aproximately over 15 % of the patients with a severe asbestosis develop broncogenic cancer 20 or 40 years later (later cancer). The danger for developing this type of cancer increases 10 times in people with asbestosis and 90 times in smokers. In different investigations carried on in patients with asbestosis, 1 from 5 deaths was caused for lung cancer , and 7 % correspond to peritoneum and pleura mesotelioma. There is also a double proportion with respect to the normal of esophagus, stomach and colon carcinoma.6)

5.2 Alternative material searching

Flexure and compression essay results over 28 days, of both mixtures (esparto grass and bagasse) are shown in the following tables:

Test Tubes	Flexure Resistance		Compression Resistance	
N⁰	Rupture Load [Kg]	σ Rupture [Kg/cm²]	Rupture Load [Kg]	σ Rupture [Kg/cm²]
1	13,59	3,18	39 52	2,44 3,25
2	13,59	3,18	65 52	4,062 3,25
3	13,59	3,18	65 65	4,062 4,062
4	9,68	2,27	65 78	4,062 4,875
5	13,59	3,18	65 65	4,062 4,062
6	13,59	3,18	78 52	4,875 3,25

Table 1: Reinforced test tubes with esparto grass

Test Tubes	Flexure Resistance		Compression Resistance	
N⁰	Rupture Load [Kg]	σ Rupture [Kg/cm²]	Rupture Load [Kg]	σ Rupture [Kg/cm²]
1	182	20,47	1560	15,60
2	150	16,87	1925 1980	19,25 19,80
3	195	21,94	1911	19,11
4	160	18,00	2400 2520	24,00 25,20

Table 2: Reinforced test tubes with bagasse

6 Conclusions

• How asbestos fibres produce the lung fibrous reaction or the way that provokes a carcinogen action in different organs is still unknown. But even when the pathogenesis is not known, the existing data show that asbestos strength the action of other carcinogen hydrocarbons.

Large cities population are exposed- to this contaminant and particularly asbestos workers and users.

• The obtained resistances in mixture with esparto grass have been little encouraging, even more in the compression ones, new dosifications will be tested with another fibres percentages.

Mixture results with bagasse aggregate are more optimistic, what allows to continue with them to find searching alternative material.

The use of earth in the construction of ecological dwellings.

D. Klees and M. Natalini
Stability Department, Engineering College, Northeast National University, Resistencia, Chaco, Argentina.

Abstract
The use of earth as a construction material presents an evolution from remote times. It was used in the construction of fortifications, temples and dwellings. Today, due to the lack and costs of energetical products, techniques should be improved in order to utilize material that can reduce these costs. The use of earth for its low consumption of energy -which is obtained with a good architectural design, thermical control, recycle posibilities of the material, the limited incidence of transportation, and the absence of combustion in its elaboration- constitutes a powerful ally in the defense of ecology. Earth presents several economic advantages: it occupies almost exclusively local resources, workmanship, raw material, and it requires just a little investment for industrial equipment. Although the use of earth has been a widely known technique for many years, it is not currently used in this area. Superficial natural earth representative of our region is a clayey soil and it is not apt for this kind of construction. The incorporation of sand with a fineness modulus greater than 2.50 and with predominance of thick fragments permits to obtain an artificial soil apt for the fabrication of modular elements of soil cement. Based on flexure and compression results of normalized test tubes, quantities of soil-cement with the best behaviour were chosen for blocks elaboration. Artificial soil B (60 % land + 40 % thick sand) mixed with 10-12 per cent of cement permits to obtain the best results in resistance, retraction, and durability. It arises then that using an actualized technique and adequate projects it is possible to construct low costs dwellings with both good thermic and acoustics conditions and durability.
Keywords: construction material, earth, ecological dwellings, modular elements of soil-cement.

1 Introduction

Since cities were invented, 10 thousand years ago, men has used earth to construct fortifications, temples and dwellings. The use of earth mixed with cement supported by scientific bases started with the construction of a 2,4 km road section in Johnsonville - South Caroline - U.S.A, with successful results. The French architect Francois Cointreaux (1740-l 830) invented in 1787 different processes to "stabilize" earth and make it more resistant in its mechanical and chemical aspects (1). He also published several studies that were widely aknowledged in Europe, America and Australia. His charts helped the constructing of public buildings, castles and dwellings up to 5 floors.

In the beginning of the XX century this kind of architecture starts to languish before the appearance of industrial materials such as steel, cement and reinforced concrete. Since 1972 the energy and the economic crisis lead to changes in the way of thinking and started to appear alternative methods specially those concerned with energy saving in construction (1). There are recent experiences of constructions performed in developed countries like France and closer to up Chile, Brazil and Paraguay (2).The construction of such dwelling in our country was posibility of two engineers, Adolfo Grissi and Victor Carri who worked at the Essay Laboratory. At the same time the Argentinian Institute of Portland Cement built - with the same material- a dwelling that was exposed at the Cattle Exposition of the Rural Society in 1944 (3). There were several experiencies with the overlapping of soil-cement in many Argentinian provinces: Chaco 1960, Tucuman 1967, Jujuy 1969, and in different localities of Buenos Aires: Lobos 1971, and Junín 1973, as well as Mendoza 1977, Salta 1981, Chaco 1991, with excellent results (3). Although earth construction is a well known technique over the years, it is not currently used in our region except in indigenous and low economic resources population (2). Overlaping earth-cement provide the rationality of its fabrication process and technical qualities, such as: high mechanical resistance, moisture resistance, dimensional regularity and a competitive cost (4). Overlaping earth-cement uses as raw material non fertile land: ecological brick (5). Earth that comes from the fertile layer is not apt for the reaction with the cement and the hardening, on the contrary, they are more advisable the ones that have in its composition a high percentage of sand. This land hasn't to be calcine because with the cement incorporation, the particles behaviour is modified, the stability improved, giving it more resistance and durability (6). The superficial and natural earth representative of our region is a clayey soil and it is not apt for this kind of construction. The incorporation of sand with a modulus greater than 2.50 with predominance of thick fragments permits to obtain an artifical soil apt for the fabrication of modular elements of soil-cement.

According to the flexure and compression results the best quantities for elaborating the blocks were chosen (7). Artificial soil with 60 % of soil plus 40 % of "thick" sand mixed with 10-12 per cent of cement allows to obtain better results in mechanical resistance, hardening and durability. It arises then, that using an actualized technique and adequate projects it is possible to construct low cost dwellings with both thermic and acoustics conditions and durability.

1.1 General objetives

Utilization of a natural and no contaminant materials. It practically uses any kind of soil, except the organic, no renewable. It is an ecologic system of construction.

The exploitation of regional materials, with a minumun cost, what allows to reduce the construction cost. The use of earth avoids the importation of expensive materials or the comsuption of energy to produce them. The transportation of materials is reduced only to the cement movement because the overlapping is produced at the place of work.

The use of unskilled workmanship. The utilization of this material does not require skilled workmanship, needs only a mason and the rest of the staff can be just assistants.

1.2 Particulars objetives

Elaboration of modular components of soil- cement for low cost dwelling, from an existant and regional clayey soil. Due to the technic and economic advantages of this material, the existing deficit of dwellings can be reduced.

2 Material and Methods

2.1 Soil-Cement: identification and characteristics

Technically, any kind of soil with no organical substances can be "stabilize" with cement (6). A soil-cement is a compacted mixture of natural soil and cement with an optimal degree of moisture. The percentage of binding makes that the modular elements can perform the durability essay for "freezing-thawing" and "humidification drying" (8). It has an excellent thermical inertia and acoustics isolation (9). Its behaviour depends on the physical and chemical characteristics of its components and specially on the fine fraction (7). Researchers and institutions that made different studies on this particular topic established limits within which they considered that the most apt soil was: sand (40-80%), and clay - mud (60-20 %). A clayey soil was used in this study, which is representative of the superficial earth of this region. Its composition was as follows: according to the Unifyed System of Soil classification: it is a CH soil, inorganic clays with high plasticity, through the sifted of the thick fraction (particles > # N° 200), and from the Sedimentary essay of the fine fraction (particles < # N° 200), the percentages of our natural soil of sand, mud and clay were obtained: sand: 9.4% and clay+mud: 90.6%. Its unfavorable physical and chemical properties obligated us to realize a "granular stabilization" using sand in order to obtain an artificial soil apt for the study. Afterwards, cement percentages were analyzed to obtain the material for the manufacturing of the modular components. At the Soil Laboratory - Stability Department, Engineering College- samples of soil were investigated and granulometric curves, physical properties and composition obtained.

2.2 Natural soil

2.2.1 Laboratory essay
Laboratory conditions:
Temperature: 27 ° C
Relative moisture: 60 %

- Specific gravity: G= 2.64 - TEX norm N° **108 -** E
- Shieve washing N° **200:** 90.6% (passing particles) - ASTM D norm N° **1140 -**
- Liquid limit: **LL=** 63% - ASTM D norm N° 423 -

- Plastic limit: LP= 20.4% - ASTM D norm N° 424 -
- Plasticity index: IP= 42.6% - ASTM D norm N° 424 -
- Contraction limit: LC=10. 1% - ASTM D norm N° 427 -
- Natural moisture: 2.4% - ASTM D norm N° 2216 -
- Soil clasification (according to Unifyed System of Soil Clasification): LL= 63%
- Plasticity chart ⇒CH (inorganical clays with high plasticity). IP= 42.6%

2.2.2 Field essay (passing fraction # N° 40)

- Dilatation (agitation reaction): null
- Resistance in a dried stage (breakage characteristics): high to higher
- Toughness (consistency closer to the plastic limit): mean to high

Through the sifted thick fraction (particles > # N° 200) and the sedimentary essay of the fine fraction (particles < # N° 200) a granulometric curve was obtained and the contents of sand, mud and clay were measured in the natural soil. To determine the limits between these fractions by taking into account their size the M.I.T.(Massachusets Institute of Technology) Soil Classification System was adopted. Table 1.

Table l: M.I.T. Soil Clasification System

SAND		
THICK 2.0-0.6	MEAN 0.6-0.2	FINE 0.2-0.074
MUD		
THICK 0.074-0.02	MEAN 0.02-0.006	FINE 0.006-0.002
CLAY		
THICK 0.002-0.0006	MEAN 0.0006-0.0002	FINE 0.0002-Colloids

- Sand: 9.4%
- Mud: 68.1%
- Clay: 22.5%

These results allow to detect an insufficiency in sand contents and a high plasticity clays excess compared to the normal values previously mentioned. The real granulometric curve is the one in relation to the natural soil (N), and the pattern granulometric curve is in relation to the soil with the best percentage of sand, clay and mud (P). Figure 1. From this granulometric analysis we can determine that in order to approach the real curve to the pattern curve it is necessary to incorporate a determined quantity of thick fraction and a medium of a siliceaus sand -artificial soil-.

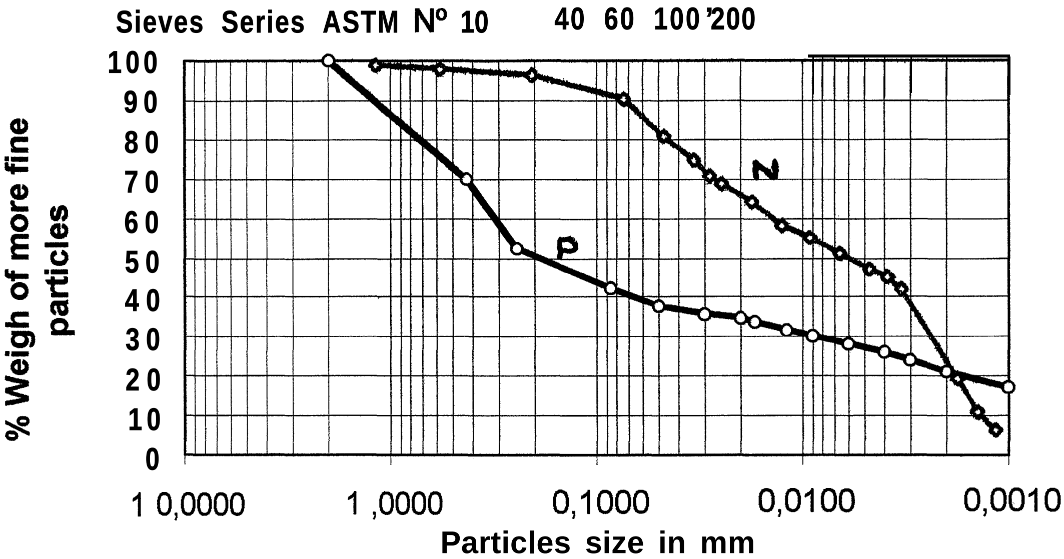

Figure 1: Granulometric soil curves for soil **-P-** and the soil material **-N-**

2.3 Artificial soils (A,B,C)

Granulometric analysis was undertaken on stabilized soil samples containing sand in three different quantities:

Soil A: 70 % Natural soil + 30 % "Thick" sand.
Soil B: 60 % Natural soil + 40 % "Thick" sand.
Soil C: 60 % Natural soil + 40 % " Mean" sand.
According to M.I.T. clasiffication and adjusting series of Standard of the American Society for Testing and Materials - A.S.T.M. -

The approximation of artificial soils (A, B, C) to the pattern soil -Figure 1- were verifyed. Different percentages of cement **(8- 1 O-12-14-1 6)** and tubes to analyze these soil-cement quantities behaviour were prepared according to I.R.A.M. norm Nº 1622.

2.4 Soil-cement blocks

2.4.1 Design

Blocks were obtained using a blockader, an improved version of the well known manual press CINVA-RAM and BREPACK PRESS, (10) built at the Stability department. It basically is a-rectangular box where the soil is deposited and pressed into blocks, three at a time. Blocks dimensions are: width: **12** cm, high: **12** cm, and length: 24 cm. There are trunkpyramidal elements at the bottom of the box and they are used to hollow the bricks when they are pressed. Figure 2.

2.4.2 Manufacturing

To mix the soil with the cement, both have to be dried in order to integrate them correctly (8). The high clay content of the natural soil produces dried and high toughness clods.

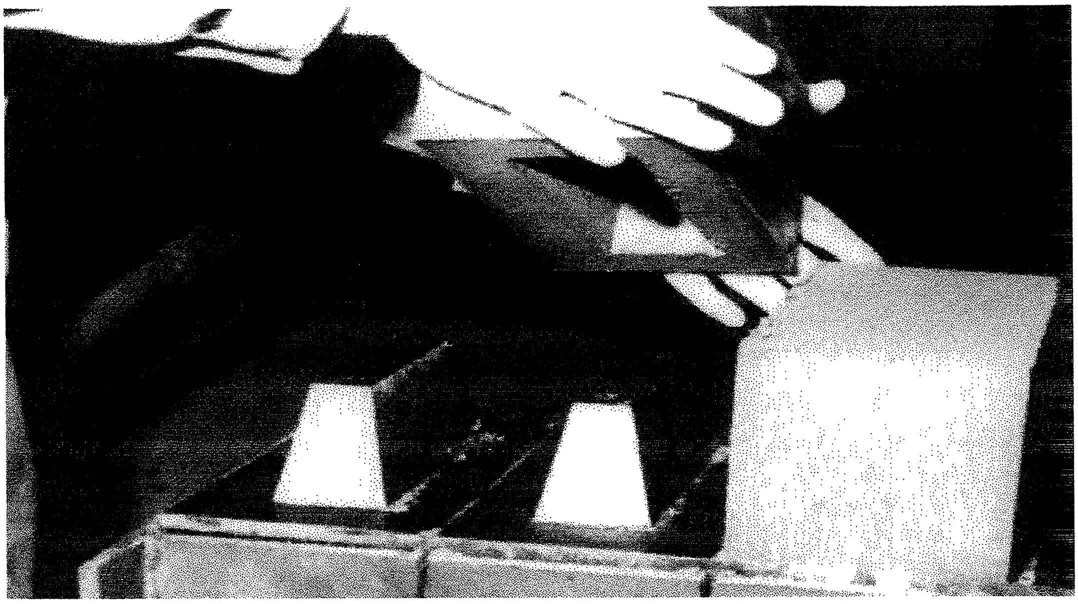

Figure 2: Blocks extraction from the blockader.

A cylindric and manual roller which has a diamenter of 35 cm, a length of 65 cm, and a weigh of 250 kg was used to facilitate the pulverization tasks of these clods and to increase the production of the available soil. According to the spectre of soil quality available the moisture content oscillates fi-om 8 % to 16 %. A water excess makes the compactation harder because of the slipping of the particles, and produces a greater tendency to fissure. There are two ways of verifying in situ if the mixture has the best moisture: 1) it must be compressed using the hands, and it has to adopt their shape without stain them, and 2) the pressed material must be dropped down from the shoulders height, and it has to disperse staying as it was before of being pressed (8). After the moisture verification the mixture was discharged into the blockader -Figure 2- for its compactation. Subsequently, the blocks were removed for their hardening. -Figure 2-. The hardening consists on spray the blocks over 7 days -at least once a day- and store them protected from the sun action in a ventilated place.

2.4.3 Essays

From the flexure and compression results of the normalized tubes, the best quantities of soil-cement were chosen for the blocks elaboration, which were the A and B soils with 8-10-12-14-16 per cent of cement.

On the other hand, in order to diminish the production costs -workmanship, materials and time- a new artificial and stabilized soil with natural sand from Paraná river was introduced. This sand has a fine modulus of 1,95 and it is representative of the siliceous sands that are comercially obtained. These blocks went through a simple compression essay using an universal press.-Figure 4-. The normalized pillars of blocks settled in mortar with the same quantities also went through a compression essay. Pillars were constructed to analyze the retraction effects, as well as the adhesion and durability.

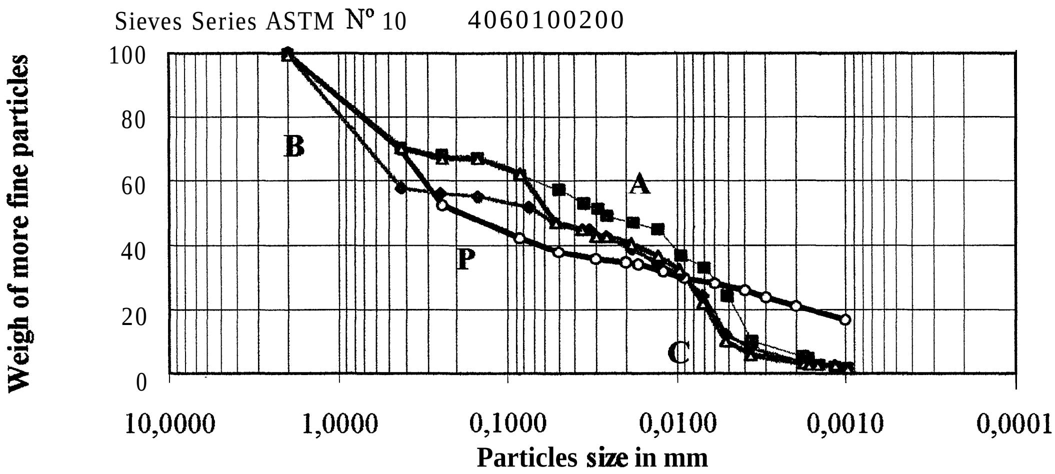

Figure3: Comparation between pattern soil curves (P) and artificial soils (A, B, C).

3 Results

3.1 Granulometric essay of the artificial soils.

<u>Soil A:</u> 30 % natural soil + 30 % '"thick" sand
Sand: 38,2 % LL: 45,8 %
Mud: 55,9 % LP: 16,5 % → according to S.U.C.S.: **"CL";** H.R.B.: A-7-6 **(15)**
Clay: 5,9 % IP: 29,3 %

<u>Soil B:</u> 60 % natural soil + 40 % '"thick" sand
Sand: 48,1 % LL: 44,9 %
Mud: 48,0 % LP: 18,1 % → according to S.U.C.S.: **"CL";** H.R.B.: A-7-6 **(10)**
Clay: 3,9 % IP: **26,8 %**

<u>Soil C:</u> 60 % natural soil + 40 % "mean" sand
Sand: 38,0 % LL: 25,3 %
Mud: 58,6 % LP: 12,3 % → according to S.U.C.S.: **"CL";** H.R.B.: A-6 (5)
Clay: 3,4 % IP: 13,0 %

3.2 Compression essay of the soil cement blocks

From the preliminary analysis of the tubes, artificial soils A and B were the ones with the best behaviour. The artificial soil D made of 60 % of natural soil and 40 % of natural sand without sifting was also included.

Maximum resistance values in compression at 14 days correspond to the mixtures with B soil, about 25 kg/cm. From the durability, retraction and mortar adhesion analysis the best results were obtained with B soil + 10-12 per cent of cement.

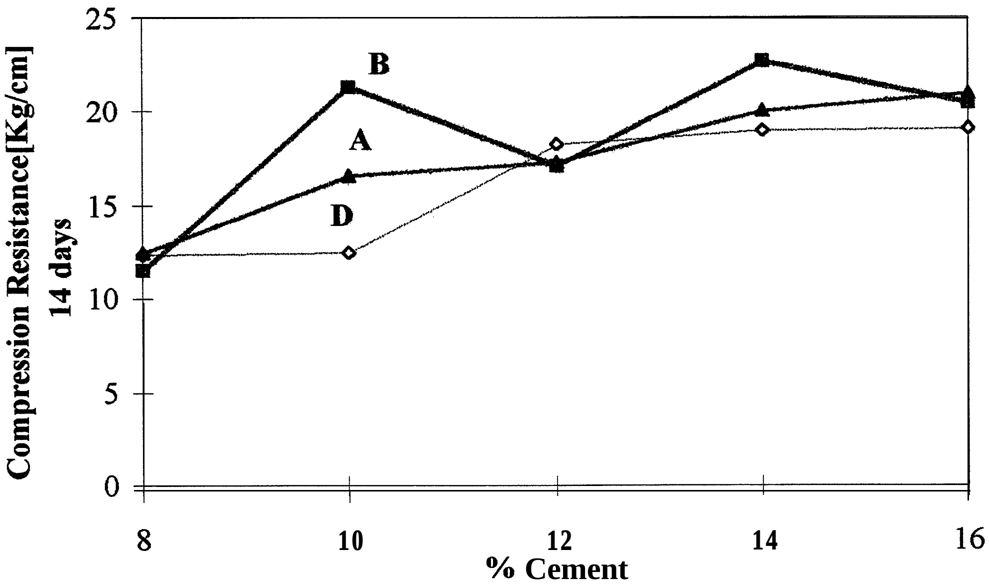

Figure 4: Compression resistant of soil cement for different percentages and artificial soils.

4 Conclusions

- An excess of clay produces important retractions, that leads to fissures and reduces the final resistances.
- Better mechanic properties were obtained when the relation between mud and clay was closer to the unit.
- The block retraction was controlled incorporating sand to the "stabilized"clayey soil, which also increased its resistance and durability.
- Production of this material occupies almost exclusively local resources - workmanship and raw material- which reduces the costs.
- The artificial soil B (60 % of soil + 40 % "thick" sand) mixed with 10-12 per cent of cement permits to obtain the best results in resistance, retraction and durability.
- The obtainment of thick sand through sifted increased the production costs, therefore, it is advisable to use a natural thick sand from the Paraná river, with a fineness modulus of 2,50.

Abstract

Advances in the experimental equipment and data analysis have shown, that ultrasonic pulse echo technique can be used in bridge inspection to detect different types of defects

- injection faults in tendon ducts, because they lead to a loss of basic protection of the tendon steel and may result in corrosion damage
- compaction faults or honeycombing, because the reduce the concrete strength and therefore may influence the static stability.

To overcome the problems of low signal-to-noise ration and bad coupling conditions of the ultrasound to the rough concrete surface a combination of piezoceramic transducer and receiving laser vibrometer was used to scan a 2D aperture. The ultrasonic RF echoes received were digitized and stored in a PC for 3D-SAFT (Synthetic Aperture Focusing Technique) reconstruction, which performs a focusing of the ultrasound into the material leading to an improved signal-to-noise ration and a 3D-image of the internal structure of the concrete.

The EFIT-code (Elastodynamic Finite Integration Technique) was used to model the ultrasonic wave propagation in the concrete and the interaction with tendon ducts of good quality and the case of injection faults. These simulations showed, that the behaviour of the interaction differs for both situations leading to an evaluation scheme to detect injection faults. Compaction defects are detected by an increased attenuation of the ultrasound leading to a suppression of the echoes of e. g. the tendon duct.

In cooperation with the Federal Highway Research Institute (BASt) test measurements on a specimen containing artificial defects were carried out, which confirmed the prediction of the EFIT modelling.
Keywords: injection faults, modelling ultrasonic wave propagation (EFIT), prestressed concrete, reconstruction calculation (3D-SAFT), scanning laser vibrometer, tendon ducts, ultrasonic testing

1 Introduction

The structural integrity of post-tensioned concrete structures is primarily determined by the condition of internal ducts and tendons. Grouting faults in tendon ducts must be revealed as the tendons are susceptible to corrosion when they are not completely covered by mortar. Compaction faults around the tendon ducts are frequently other causes of damage and failure.

Today the regular inspections of engineering structures are mainly visual assessments. This implies that any damage is in general only identified when deterioration becomes visible. There is a demand for non-destructive testing methods in this area in order to establish the condition of structures and to identify faults before they become visible through deterioration effects. It will help to reduce costs and to extend the service lifespan, when regions to be maintained can be pinpointed early.

Non-destructive test methods such as radiography and impact-echo methods have so far been applied for identifying such problems. Radiographic techniques may only be applied when the component to be examined is accessible from two sides and moreover, these methods have their own attendant problems in connection with radiation protection measures. The second method has been widely applied, but its performance is judged differently.

We report on experiments using an ultrasonic echo system. To overcome the known difficulties encountered with ultrasonic testing of concrete due to the inherent properties of the material, an enormous progress can be stated in the last years [1][2][3][4]. For the method described in the present paper, ultrasonic signals in a so-called synthetic aperture are processed to obtain three-dimensional images and the ultrasonic backscatter and reflections from the area below the synthetic aperture are calculated. We used a bistatic measurement principle, i.e. separate ultrasonic transmitters and receivers were employed. The results were visualized and may be superimposed with the construction plan or the results of other imaging measurements.

In order to predict, what is possible to measure in concrete structures by use of ultrasonic echo methods, simulation calculations by the Elastodynamic Finite Integration Technique (EFIT) have been applied. The propagation of elastic waves in concrete was simulated in dependence of the concrete admixture and the presence of defects.

2 Experimental Set-up

Significant amounts of data of several thousand positions are required to reconstruct meaningful images. BAM has developed a special test arrangement with a laser vibrometer as the ultrasonic receiver in order to automate data recording and to reduce the problems of positioning and coupling the transducer [5]. The ultrasonic transmitter is piezoelectric with a centre frequency of about 100 kHz.

The laser vibrometer registers all surface vibrations within a wide frequency range of 0.1 mHz to 1 MHz, i.e. the vibrometer measures all relative motions between the vibrometer and the surface to be measured (in the direction of the laserbeam). Undesired vibrations may easily suppressed by frequency filtering and time averaging techniques [6].

If a large structure is to be examined, several surfaces areas with different transmitter positions must be scanned. The scanned areas should overlap to produce optimum results. The position of the tendon duct should be known to install the transmitter most effectively, this can be ascertained by the radar method [4][7][8].

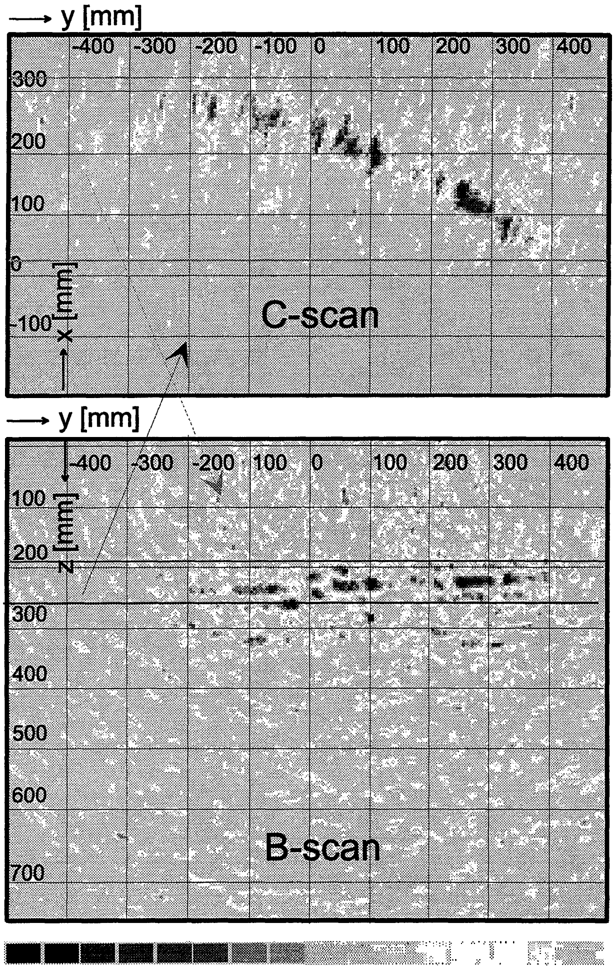

Figure 1 (left): Result of 3D-SAFT reconstruction showing a tendon duct, for details of the specimen, see Figure 7. The experiments were carried out from the back side of the specimen as shown in Figure 7.
Upper part: top view (C-scan) of the projection from a chosen depth range indicated by horizontal lines in the B-scan.
Lower part: side view (B-scan) showing the y-axis vs. depth. Reflections from the near and the lower surface of the duct are seen at ca. 230 mm and 320 mm, respectively.

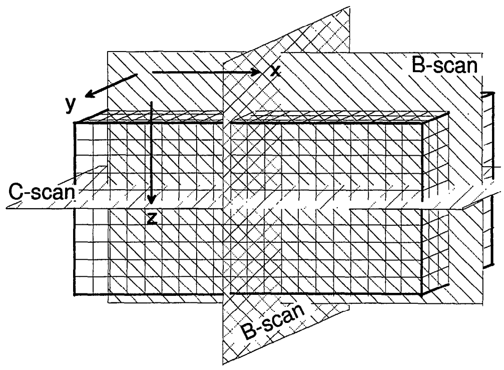

Figure 2: Principal sketch for the projection planes of the results of a 3D-SAFT reconstruction.

3 Evaluation methods and simulation of acoustic wave propagation

To get a rough idea of the geometry inside the material examined The data are evaluated by a time-of-flight-corrected technique [5].

Three-dimensional reconstruction images are obtained by the Synthetic Aperture Focusing Technique (SAFT). High-frequency echoes (HF-A-scans) from the interior of the component are registered, digitized, and superimposed in a special way. In principle this corresponds an averaging of high-frequency signals. A 3D-SAFT reconstruction method was applied for our inspections. After rectifying and filtering the three-dimensional distribution of reflections and backscatter from the interior of the tested object will be obtained [9][10].

The 3D-SAFT results are visualized as two dimensional projections from the three-dimensional reconstructions of the scattered ultrasonic waves. Figure 1 shows the reconstructed image of a tendon duct. An interpretation will be given below. In the upper part of the figure the top view of the projection from a chosen depth range of the interior of the tendon duct is shown (C-scan). The limits of the range of projection is indicated by horizontal lines. The lower part of the figure is a side view (B-scan) showing the depth of the scattering centres. The projection range of the x-axis is also indicated. As a principal sketch Figure 2 shows the reconstructed volume and the position of the planes of projection.

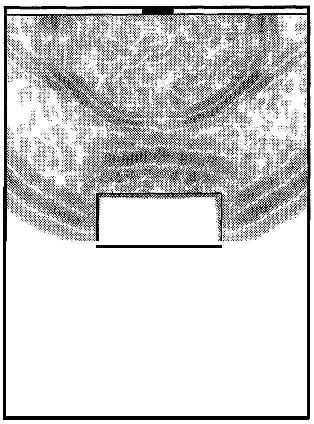
The long wavelength of about 50 mm and the lacking sharpness of the image indicates why these projections should be studied instead of sections. In addition, it should be noted that the tendon ducts are in general bent and are usually not embedded parallel to the surface.

As mentioned above the results described in this paper deal with the localization of grouting defects in tendon ducts and compaction defects around the ducts.

The EFIT-code (Elastodynamic Finite Integration Technique) has been used to model the ultrasonic wave propagation in concrete with tendon ducts of good quality and in the case of injection faults. A description of this method is given in [11].

In this example a 500 x 680 mm concrete specimen has been investigated. The base material is cement and the additives used are granitite, basalt, and plaster with a maximal aggregate size of 16 mm and a grading curve Al 6. The additives have been modelled by 260,000 ellipses varying statistically in size and orientation. A normal pressure probe with a centre frequency of 80 kHz has been used. The time history of the pulse is modelled by a raised cosine with two cycles. The probe has a diameter of 50 mm. On the one side the tendon duct has been modelled as a circle (cross section) and on the other side as a rectangle (longitudinal section). The thickness of the duct is 1 mm, the cross section of the circle is 90 mm, and the size of the rectangle is 200 mm x 90 mm.

The depth of the embedded duct is 300 mm. To identify the echo signals of the duct properly, the concrete has been simulated without any air inclusion. It has been shown [8] that there is a strong dependency between the damping of the elastic wave and the percentage of air inclusions. A two-dimensional modelling setup yields the upper limit of about 6% of air for the detectability of a reflection signal.



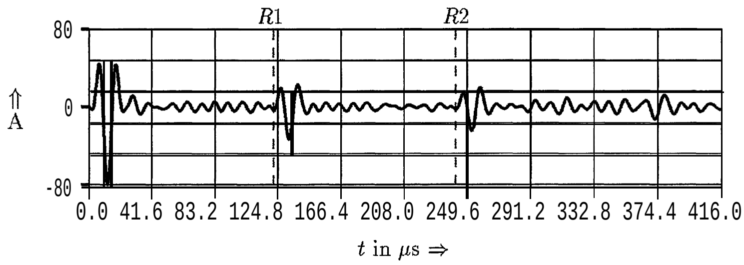


Figure 3: EFIT-simulation of an air filled duct (longitudinal section). The A-scan (above) clearly shows the multiple reflections R1 and R2 between the duct and the surface of the p-wave. The wavefronts are shown in the snapshot (left) at a time of 83.19 μs.

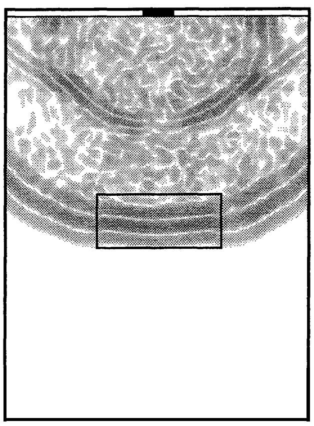

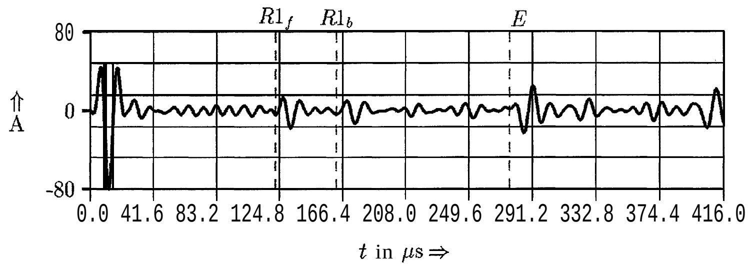

Figure 4: EFIT-simulation of a cement filled duct (longitudinal section). The A-scan (above) shows the front and back side p-wave echo ($R1_f$, $R1_b$) of the duct and the backwall echo E of the specimen. The snapshot of 83.19 μs gives an impression of the wavefront penetrating the duct

The perfectly filled duct is modelled as filled with cement, the non-perfectly filled duct is modelled as completely filled with air. Figure 3 shows a snapshot of the wavefield simulated with EFIT and the expected A-scan for a longitudinal section. The transducer is shown in all figures at the top of the wavefield. Figure 4 shows the same situation for an air filled duct. Both figures clearly show the pressure (cp) and the shear wave fronts (cs). The air filled duct shows a reflection of the duct surface (R1) only. For the cement filled duct the wavefronts travel through the duct. The respective A-scans clearly identify this fact.

The amplitude of the reflected signal $R1_f$ is significantly higher in the case of an empty duct. But the filled duct only gives an indication of the back side of the duct ($R1_b$). The scattered signals may be explained by the wave impedance of the media. Together with the size and the shape of the duct the scattered signals depend upon the difference of the wave impedance between duct and filling. A bigger impedance difference gives a bigger reflected signal. The transition from steel to air gives such a big step in the impedance profile that the incident wave is totally reflected. This is the reason why the back side of the duct cannot be detected.

Figures 5 and 6 reflect the same behaviour for the circular cross section. But the curved surface of the duct reflects less energy in direction of the receiver, and therefore the amplitude of the signal is smaller.

In conclusion the following principles may be deduced from the simulation in order to evaluate the 3D-SAFT reconstructions and to identify defects:

1. The interfaces between concrete/steel/air (empty duct) lead to higher amplitudes of reflected ultrasonic waves than the interfaces between concrete/steel/grout (filled duct).

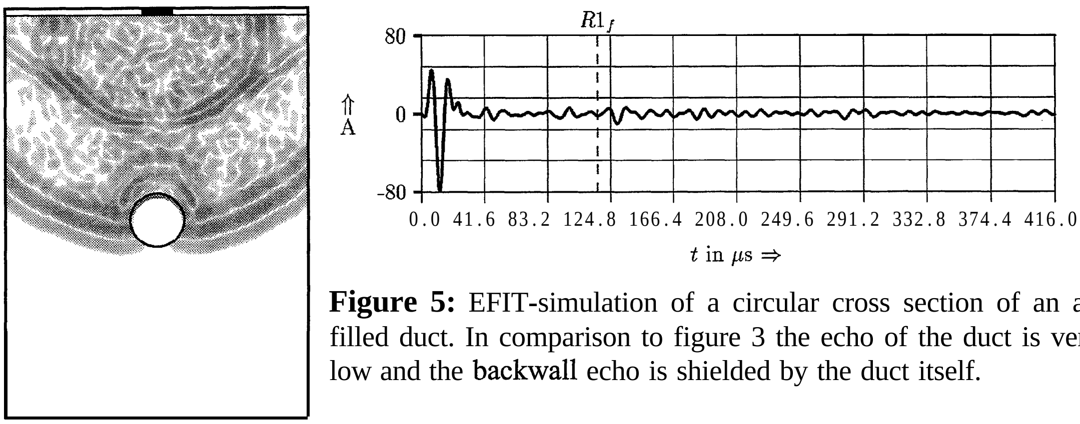

Figure 5: EFIT-simulation of a circular cross section of an air filled duct. In comparison to figure 3 the echo of the duct is very low and the backwall echo is shielded by the duct itself.

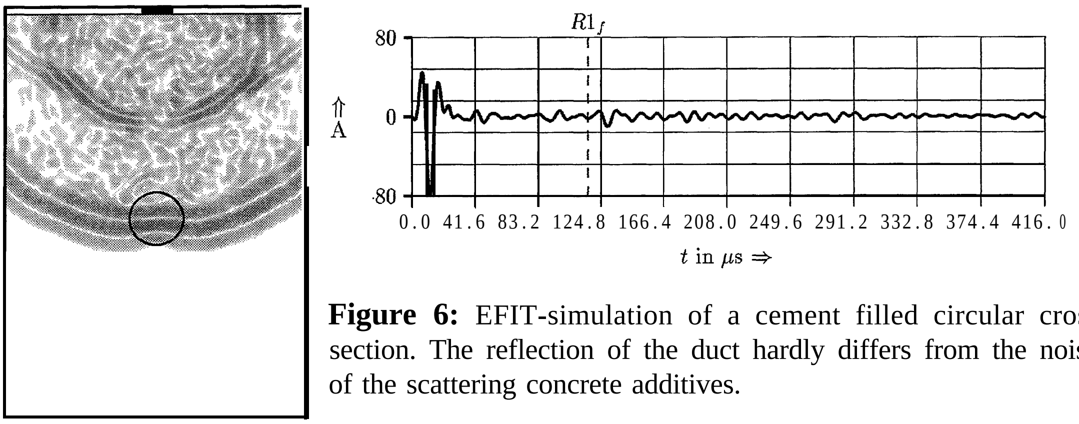

Figure 6: EFIT-simulation of a cement filled circular cross section. The reflection of the duct hardly differs from the noise of the scattering concrete additives.

2. When the ultrasonic waves travel through the interface concrete/steel/grout, the ultrasonic energy passes and partly it is reflected from the lower surface of the tendon duct. In case of grouting defects in the tendon duct no ultrasonic energy passes into the duct and therefore no image of the lower surface will be obtained.

Additionally it is assumed, that a compaction defect around the tendon duct means that there is no clear interface between the concrete and the loose aggregate. Such an area is likely to scatter the ultrasonic energy diffusely and to have a smaller amplitude than the reflection of the duct, the echo of the duct will vanish.

4 Results

We present the results obtained by a round robin test which was carried out in cooperation with the Federal Highway Research Institute (BASt). Radar and six different ultrasonic test methods, impact-echo and simulation calculations were used to compare and assess the present state of technology of these methods [5][8]. The test series were carried out as blind tests, i.e. the construction plans were revealed after the tests. In the present paper only the results are presented which were obtained by the ultrasonic method described.

The construction plan and the results are presented in Figure 7. The tendon ducts to be identified were partly embedded behind grid rebars (spaced 150 mm, diameter 12

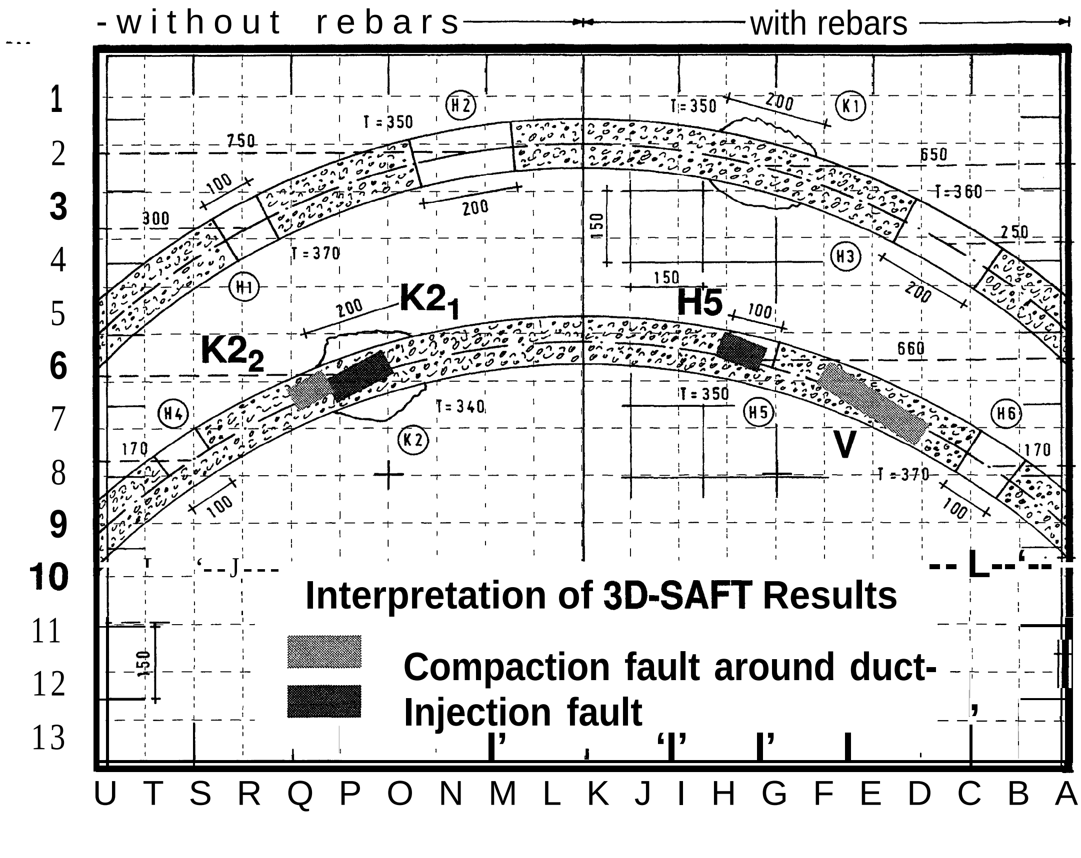

Figure 7: Construction plan for the specimen for the blind test series at BASt (dimensions in mm). Compaction faults (K) and injection faults (H) are intentionally placed around and inside the two ducts.

The grey fields indicate the location of the defects at the lower duct interpreted from ultrasonic testing. V: Compaction defect, which was not intended. The results presented in Figure 1 were measured from the back side.

mm), additionally stirrups were inserted. The lower tendon duct was scanned with the laser vibrometer at 12 different transducer positions and the defects were interpreted from the 3D-SAFT reconstruction. One void (H5) could clearly be identified and a compaction fault around the tendon duct (K2) could be detected quite accurately. However, a part of the compaction fault had been misinterpreted as a grouting defect and one not intended compaction defect was identified.

An example of the 3D-SAFT reconstruction of six measured partly overlapping areas in the part without reinforcing rebars of the test specimen is shown in Figure 1, as mentioned above (for further information refer to the references [5][8]). In the upper part of the figure the bent tendon duct can be identified (C-scan) while in the lower part (vertically to the surface, B-scan) its near surface and about 90 mm below its lower surface may be recognised.

In the upper tendon duct of the specimen the defects were measured after the construction plan was revealed and the grouting defects were additionally localized by destructive testing. Here the lower surface of the duct is not clearly detectable in the reconstruction. So the intensity of reflection was taken into account for the interpretation. In Figure 8 the C-scan obtained with the 3D-SAFT reconstruction is superimposed to the design sheet and the defects measured by destructive testing. The points of high intensity of reflected ultrasonic waves fit most of the intentionally and unintentionally placed defects.

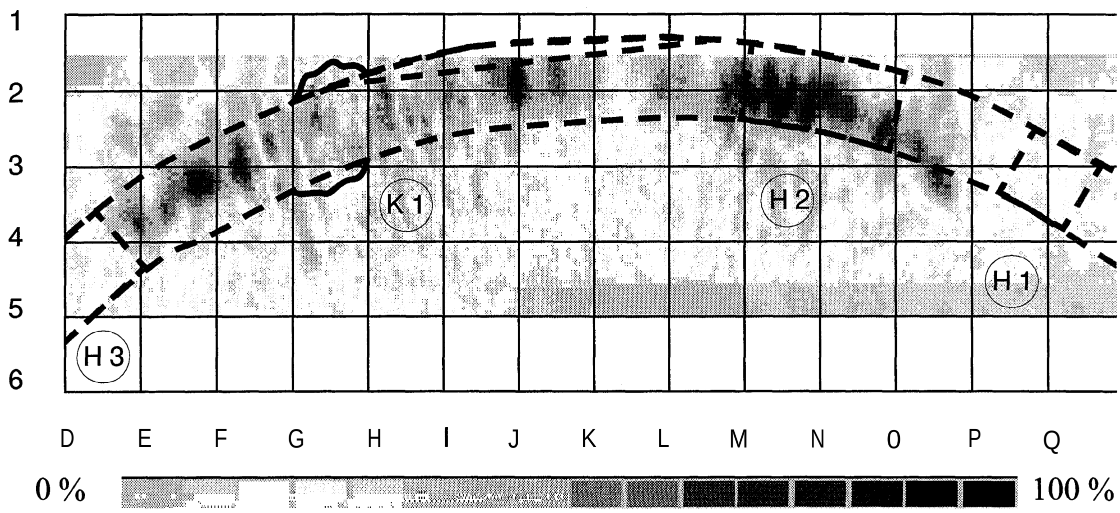

Figure 8: Result of the 3D-SAFT reconstruction at the upper duct of the test specimen of BASt, measured area from axis E to P (see figure 7). This view is shown from the opposite side compared to figure 7. The C-scan is compared with the result of destructive testing of the specimen. High intensity of reflected ultrasonic waves fit with intentionally and unintentionally placed defects.

5 Conclusions

A modification of the ultrasonic pulse echo method using the Synthetic Aperture Focusing Technique provides an imaging system for the detection of internal structural changes in reinforced concrete components. The data obtained were reconstructed by means of 3D-SAFT revealing the image of tendon ducts in concrete. The exact position of the tendon ducts and the depth of the concrete cover could be clearly detected. The method has been applied successfully on a concrete specimen of common characteristics (maximum aggregate size 16 mm, pore content 5 %, depth of the tendon duct 300 mm) and was able to work in presence of grid rebars (spaced 150 mm, rod diameter 12 mm).

From the modelling of the ultrasonic wave propagation in concrete the principles of the interpretation of the results could be deduced. The modelling was performed for the concrete admixture and the dimension of the specimen under investigation.

The good performance of this method was demonstrated in a blind test where several defects in and around tendon ducts were detected.

The high pore content of the concrete complicates the interpretation of the results, as it was also demonstrated by the modelling. It becomes evident that the localization of most of the defects is only possible using scanning systems including reconstruction calculations.

When the lower surface of a duct is not visible in a reconstruction at all, an evaluation of the intensity of the reflected ultrasonic signals is necessary. Then not all defects can, however, unambiguously be identified because the intensity differences of the signals often are not distinct enough. Work on improving the measurement technology and reconstruction calculation, as well as simulation, must be continued at this point to support the interpretation of defects.

The described results at test specimens presented in this paper show, that ultrasonic echo methods can identify important defects in post-tensioned concrete structures. It is a very useful task to develop those methods to be used for the condition assessment of engineering structures in order to assure the durability and to obtain data for the decision, whether an construction is still in a serviceable condition or not.

6 Acknowledgments

We gratefully acknowledge financial support from Federal Highway Research Institute (BASt) for the round robin tests.

Socio-Economic Changes and Sustainable Construction

G. Seaden
University of Ottawa, Ottawa, Canada

Abstract
Western industrialized countries are evolving in their approaches to governance and to economic growth. Many are moving away from a central, welfare for all, top down model to a devolved, small, less interventionist type of government. Independent firms and individuals are expected to ensure their own development. Government is limiting its activity to facilitation and catalytic role.

In that context, sustainable construction approaches and technologies need to be reviewed. Since the very definition of sustainability involves "future generations", current governance, economic and technology systems may not be adequate. The old egalitarian approach of Western democracies, as well as the new minimalist state, do not appear effective in addressing sustainability issues. The free-market capitalism has also shown many limitations in that regard. Nevertheless, in the present socio-economic system, there are opportunities for "win-win" situations, where construction, through enhanced design and technology combined with better public awareness, can achieve environmentally positive results.

Current, incremental mode of technological change requires acceleration and additional research needs to be undertaken in the areas of general modeling and assessment of constructed ecosystems as well as in the understanding of avoidance of environmental hazards, remediation and restoration.

In the face of shrinking markets for new construction in the Western industrialized countries, sustainable construction practices can represent new business as well as an opportunity to create a positive image for the industry.
Keywords: sustainable construction, evolving socio-economic forces, new business opportunities, technology and regulatory challenges

1 Introduction

World has been concerned with the sustainability issue for some time. In the 1970's, an influential international group "Club de Rome" produced a report "Limits to Growth" [1] which was based on estimates of rapidly disappearing natural resources required to sustain life on the Planet Earth. Significant, science based debate started but because of the "zero-sum" nature of the analysis and insufficient consideration of the adaptability of market forces and the potential of technological changes, this report was considered overly pessimistic.

The pressures on world's eco systems (including a number of mini-catastrophes) continued and in 1987, World Commission on Environment and Development produced the report "Our Common Future" [2], often referred to as The Brundlandt Report: It provided what is now broadly accepted as the working definition of sustainable development: "that meets the needs of the present without compromising the ability of future generations to meet their own needs".

Thus, an alternative goal became available to economic development, with considerable interpretation difficulties of inter-generation perspective and need for long term environmental impact knowledge.

Since then, there has been growing concern about various symptoms such as widespread deforestation and desertification, greenhouse and ozone-depleting gases, pressure on arable lands, and in general, doubt that conventional policy, economy and technology approaches may be adequate to deal with the complexities of sustainability and that new approaches may have to be proposed.

The very definition of sustainable development, with its long-term view, challenges currently available scientific data as well as presently known "holistic" models of interaction between ecology, sociology, economics, policy making and technology development. However, action to reduce risk should not await scientific certainty. Precautionary principles of public policy suggest that preventive action must be initiated at early stages while more precise scientific evidence is obtained to prove causality.

There have been numerous attempts to review construction activity from sustainable perspective, particularly various processes, systems and materials. There is no doubt that construction has a very significant role in the sustainable development context:

- through its size, as a very large industrial sector, representing 10%-15% of most countries economies
- through transformation of raw and semi-processed materials and changes to environment, it creates approx. 2/3 of world's fixed assets, characterized by long life and potential for further environmental impact at the repair, demolition or re-use stage,
- it is the largest industrial source of solid waste, in Canada accounting for close to one third of the total
- it is a very significant user of energy in many countries, up to 50% of total being consumed in the operation of constructed facilities
- it is capable of environmental intrusion as well as of problem remediation, with total downstream effects not always well understood

At the present time there is considerable debate, locally, nationally and internationally as to the appropriate environmental goals and standards for most human endavours **[3].** Thus it is considered useful to review construction from the perspective of sustainable development.

It is proposed to use a "system" approach, while being aware that our knowledge of linkages between the sub-systems is incomplete and that dynamic changes are continuously taking place. Most of trends presented are based on review and knowledge of current or emerging practices in Western Europe and North America. It is not clear how such practices apply to Asian countries or to other parts of the world. Given the global diversity, we believe that generalizing our findings may be already somewhat bold and ambitious.

In the first place, we shall review changes taking place in the governance structure of many countries and underline the ever important role of government(s) in environmental matters. Then, we shall look at the market mechanisms currently in place and their ability to deal with short- and long-term factors and externalities. Scientific development has been suggested as a solution as well as a problem to many pollution situations. We shall look at the major groups of technologies that hold promise. Finally, we shall suggest to the construction industry major new business opportunities and challenges, as the world gears up to deal with its future.

2 Governance trends

As previously defined, sustainable development involves intergenerational concerns and, in many instances, transborder movement of polluting matters. Thus, one can reasonably assume that government(s) have an important role to play in defining appropriate policies and collective actions. Significant changes are now taking place in policymaking process, which are already having impact on sustainability problems and solutions.

One of the powerful policy themes of Western democracies, for a significant time, has been the egalitarianism. This philosophy, which has been at the centre of the concept of welfare state, believes that equal opportunities and rights is a desirable objective and that every citizen should be provided with an equal access to available resources, As well, it is generally agreed that there is a principle of governance that ensures the integrity of a national territory, of its resources and economy. These approaches allowed national governments to promote energy conservation in buildings, declare levels of permissible volatile matter in building materials or agree on water purity standards.

New philosophies of minimalist state, of less intrusive nature, are now being introduced in various countries, where individual citizens are expected to be responsible for their own welfare and the state intervenes only in particular situations, when certain individuals are unable to cope and require help. At the same time, there appears to be a shift from top-down entitlement or assured right approach to a devolved, locally established, need-based intervention.

In many environmental instances, such as location of solid waste disposal site, acceptance of certain construction styles or local building materials, such less bureaucratic, more direct and efficient policy making process may appear to be desirable.

How will this shift affect sustainable development policies of a broader nature is uncertain. In North America, where construction is generally under local jurisdiction there is little evidence of long term foresight at that level while more senior governments are involved in massive consultation undertakings, attempting to reconcile often contradictory environmental objectives of different parts of the country or of various vested interests.

Opinion polls, community initiatives and presence of many non-governmental organizations (NGOs) continue to indicate reasonably high level of popular support for sustainability goals. Otherwise, emerging forms of policy making seem to have increasing difficulty arriving at actual decisions, particularly when faced with complex, long term, multivariate environmental problems.

Furthermore, it is not clear how broader national and multinational issues can be resolved without governance based on egalitarian principles as well as on those protecting national integrity. Introduction and transborder movement of building products that may be environmentally harmful, preservation of certain valuable tree species, protection of shared marine sites and many other construction-related problems will require a more active role of senior levels of government.

3 Economic considerations

The actual neo-liberalism or free-market paradigm broke through around 1900, then reinforced with the Schumpeterian model and the Chicago School. The entrepreneur is considered the principal driving force in the free-market, creating business organizations, with the objective of maximizing profits. The basic assumption for creating global wealth is to let entrepreneurs get rich, by free trade, 'laissez-faire' policy and reducing barriers of any kind, then wealth being distributed by their increasing consumption of goods.

Within this context, firms and individuals have destroyed natural resources because they have benefited from doing so. We became a wasteful society and inter-generation issues have been ignored [4].

In a global trade environment, where relative position of a country or a region is determined through market mechanism, there is an uneasy relationship between the cost of protection of the environment, particularly for future generations, and shorter-term economic benefit. Some suggest that market forces, as they are applied at the present time, do not adequately represent the "externalities" of the environment and even less so of the future considerations, hence the need for extra-market intervention mechanisms such as polluter fees, carbon taxes or regulations.

> "Capitalism offers immense dynamism, but markets do not regulate themselves. No policy is also a policy. Globalization does not invite an era of laissez-faire, but a thornier set of questions about governance." [5]

However, in most construction-related matters, assumption can still be made of "win-win" situations. Through better information on impacts, improved analysis and enhanced technology, facilitating market forces, combined with greater public awareness of sustainability, systems can emerge which demonstrate benefits exceeding costs for the short as well as for the inter-generation development [6].

Construction industry, amongst others, has often expressed concern with stringent environmental regulations and controls, stating that they affect its price performance within domestic markets and leaves it exposed internationally to unfair competition by certain countries where laws and/or enforcement may be more permissive. Large, European and American commodity-type producers of cement, steel, dimensional lumber and other building materials have argued that regulations impose significant business costs, diminish productivity and reduce their ability to compete successfully in global markets where certain firms can operate from "pollution havens" with lax controls and/or enforcement.

Studies of relative international competitiveness by Porter [7] and others suggest the contrary. There is evidence that very demanding domestic markets (including tough environmental protection measures), cause companies to improve their internal production and quality assurance processes and to upgrade their technology which eventually leads them to become more efficient in the use of resources. Thus they are able to develop world class products at lesser cost while achieving decreased environmental impact. Examples exist of no-discharge forest product manufacturers or of zero-waste steel fabricators that operate in high wage areas with demanding regulatory regimes yet are commercially flourishing.

These "win-win" scenarios, appear to be particularly successful under the following circumstances:

- companies or industrial sectors are technologically fit and they have research infrastructure and knowledge base which allows them to explore various innovative alternatives
- regulatory regime is of a flexible, performance nature, which allows the development of cost effective solutions rather than a narrow prescriptive standard type, which often forces expensive compliance
- customers are demanding and knowledgeable, asking for quality and performance.

Local decisions by industrial organizations are also of great importance to construction enterprises, which predominantly have local or regional focus. These decisions, after all, create direct building opportunities, which then amplify through local construction markets. In many countries, construction industry associations have been known to lobby against various sustainability measures on the grounds that these may reduce the economic growth and thus building activity. At the present time there does not appear to be satisfactory evidence that this is the case, furthermore such position may be contributing to the negative public image of the industry.

Well respected IMD of Lausanne produces annually The World Competitiveness Report based partially on surveys of senior executives, in order to obtain a blend of "hard" (numerical) and "soft"(opinion) based indicators. Recently, executives of large Western industrial enterprises, when asked to evaluate various input factors, were only mildly concerned with the relative stringency of environmental regulations [8].

4 Technology development

Significant opportunities exist to better manage construction resources but it is through increased knowledge and greater use of technology that the industry is likely to make advances in the context of sustainable development.

U.S. National Science and Technology Council [9] defined environmental technology as a 'technology that advances sustainable development by reducing risk, enhancing cost effectiveness, improving process efficiency, and creating products and process that are environmentally beneficial or benign"

Two large categories of technology development appear to be necessary:

- **Modeling/Assessment Techniques:** creation of realistic, long-term, multidisciplinary models of ecological systems, development of monitoring tools and of performance assessment techniques. Our present knowledge of "cradle-to-grave" behavior of building materials or of infrastructure requirements for an urban agglomeration is very limited. Furthermore, long term approach involves development of "organic construction" that can take into consideration short term needs as well as facilitating renovation to respond to future needs. A higher client satisfaction also involves an integrated approach for better homes or work spaces, easier transportation modes, access to recreation facilities, including fragile "wilderness" areas, and all the wants and needs of our consumer oriented society. In-process monitoring technology is also required, to replace the "end-of-the-pipe" approach with an "early warning" system. Ideally, on-line models would generate continuous stream of information that would allow building practitioners to adjust the construction process for the optimal outcome.
- **Avoidance, Remediation and Restoration:** development of technologies that will reduce creation of environmentally harmful materials, systems or processes (such as use of non renewable resources, harmful waste and pollution); increase recycling and re-use of materials; and facilitate remediation of ecosystems that have been negatively impacted in the past. For example, improved knowledge is needed of adverse impacts of substances on indoor air quality, of further improvements to energy conservation of building envelopes or, of increased recycling opportunities for demolition products.

New technological approaches are gradually being introduced to the industry but much of existing research results remain to be diffused, transformed into commercially viable technologies and put to practice

It is unlikely that there will be a single, large technological breakthrough that will transform the construction industry and make it environmentally compatible. Resistance to change by the industry and by its customers suggests that the present incremental modification of technology processes in waste management, of energy and water conservation, of recycling of materials and land, is correct but it requires acceleration, combined with greater public awareness.

5 Ecobusiness opportunities

Projections for Western industrialized countries indicate relatively low overall economic growth, in the range of 2%-3% per annum, and demographic trends of aging population. Since these are the principal demand factors for the industry, it may be expected that the domestic needs for construction, particularly for new facilities, will remain low.

On the other hand, there is great accumulation of existing buildings and civil works that require repair, rehabilitation and upgrading. Many of these projects were built under less stringent environmental regulations and their owners now face requirements of remediation to achieve healthy environment or legal liability, sometimes at criminal level.

Overall, direct costs of environmental compliance are expected to be very high and there has been some reluctance by all stakeholders to apply pressure for immediate action, nevertheless business activity in this sector has been gradually increasing. Various decisions at the regional, national and global levels regarding reduction of emissions, conservation of resources or creation of environmentally compatible projects have consequences on the construction industry.

Major markets have now been opened for designers, contractors and material suppliers and a great opportunity has been created to change the historical image of the industry, from environmentally intrusive to one of the builder of sustainable environment.

6 Challenge

Implementation of sustainable construction will not be easy.

> "Future development undertaken in an environmentally and economically sustainable manner requires new ways of thinking in planning, designing, building, operating, and maintaining the built environment." [10]

Moreover, sustainable development involves a systemic and holistic approach that appears difficult to achieve in the construction industry. This sector is highly fragmented, consisting of numerous small firms, suffering from a low co-operation culture among participants.

Governments will also have a crucial and far than obvious role to play in promoting promising technologies and developing performance based and flexible standards, with effective consensual processes involving numerous different stakeholders in the country, as well as internationally.

Action of gypsum on recycled aggregate concrete

J. L. Gallias
IUP Génie Civil et Infrastructures, Universite de Cergy-Pontoise, Cergy-Pontoise, France

Abstract

The risk of sulphate attack and ettringite formation is the main reason to limit the use of recycled aggregate in concrete. In fact, French standards exclude any possibility of use of recycled aggregate in concrete, restricting the sulphate content of aggregate for concrete to 0.15% by mass. On the other hand, the RILEM recommendation TC 121 DRG allows concrete to contain recycled aggregate containing up to 1% sulphate by mass. In these conditions, it seems important to evaluate the action of gypsum on recycled aggregate concrete and to appraise by tests if a threshold of sulphate content exists for the recycled aggregates over which concrete expansion becomes critical and mechanical strength diminish.

In this study, mechanical strengths, expansion measurements and mass controls of concretes prepared with recycled aggregates, more or less polluted by gypsum, were compared with those of natural aggregate concrete. Various amounts of gypsum were added to mortars prepared with recycled or natural aggregates and the physical and mechanical characteristics were evaluated up to 3 months of age for specimens cured in fully immersed conditions. The results obtained show that the substitution of natural aggregate by recycled aggregate in a concrete mixture having a constant water-cement ratio and workability, produces a more or less significant decrease in the compressive and tensile strength. The decrease in strength depends on the grading of the recycled aggregate and, to a lesser extent, on the origin of the raw material. The decrease in mechanical strength is more significant when fine recycled aggregate is used in the mixture.

Concerning the effect of sulphate content, the results enable us to conclude that recycled aggregates containing 0.3 to 0.8% by mass of SO_3 do not produce a significant effect on the mechanical strength and the expansion of concretes and mortars because the most part of sulphates are coming from the cement hydrates of the raw material. Only when recycled aggregates contain significant amounts of gypsum impurities (> 1% by mass) does the strength decrease. Gypsum impurities have a more significant effect on expansion of mortars prepared with natural aggregates.

Furthermore, the results show that when recycled aggregate contains more than 0.5% by mass of additional SO_3, the expansion of mortars becomes critical. When portland cement containing lesser amounts of C_3A is used in the mixture, the additional sulphate content in recycled aggregate has to exceed 1.2% SO_3 by mass for critical expansion.
Keywords: Recycled aggregate, gypsum, sulphate content, concrete, mortar expansion, mechanical strengths.

1 Introduction

Because of the lack of development of selective demolition processes in France and the difficulties to control the origin of demolition wastes arriving to recycling plants, recycled aggregates can be more or less polluted by gypsum, the gypsum usually coming from building partition-walls and plasters. Severe expansion and cracking of concrete due to ettringite formation is considered as one of the most important pathological factors related to the use of recycled aggregates in concrete.

The French standard NF P 18 541 limit the sulphate content of aggregates for concrete to 0.15% by mass of SO_3 [1] and hence, limit the use of recycled aggregates only as an untreated by hydraulic binder sand or gravel used in banking and in sub bases of minor roads. On the other hand, the RILEM recommendation TC 121 DRG permits concrete to contain recycled aggregates containing up to 1% by mass of SO_4 [2].

In these conditions, it seems important to determine using tests, if there exists a threshold for sulphate content for these recycled aggregates over which concrete expansion becomes critical and mechanical strength diminish. Firstly, concretes prepared with recycled aggregates containing more or less gypsum impurities were compared with natural aggregate concrete. Secondly, various amounts of gypsum were added in mortars prepared with recycled or natural aggregate. Physical and mechanical characterisations, expansion measurements and mass controls up to 3 months were made for specimens cured in underwater conditions.

2 Materials

2.1 Recycled and natural aggregates

Two types of demolition wastes were selected for recycling :

- reinforced concrete structures and cement or blast furnace slag treated road bases without significant gypsum impurities,
- building demolition wastes containing concrete and masonry polluted by gypsum.

For the first part of the study concerning concretes, a 0/5 mm fine aggregate and a 5/25 mm coarse aggregate were prepared with both types of wastes, named respectively CRF05 (fine aggregate obtained from recycling of concrete), CRC25 (coarse aggregate obtained from recycling of concrete), BRF05 (fine aggregate obtained from recycling of building demolition wastes) and BRC25 (coarse aggregate obtained from recycling of building demolition wastes). Both demolition wastes were crushed and screened in the same conditions in order to guarantee the same grading for the recycled products. A natural siliceous sand 0/5 mm and a natural siliceous gravel 5/25 mm, designated NF05 and NC25, having similar grading to the recycled aggregates, were also used in the tests.

For the second part of the study involving mortars, the recycled fine aggregates, designated CRF05 and BRF05, were used. The recycled coarse aggregates CRC25 and BRC25 were further crushed to a 0/5 mm fine aggregate and named CRC05 and BRC05 respectively according to their origins. Various amounts of gypsum coming from partitions walls were crushed at the same grading (0/5 mm) and added to the fine aggregates. The natural siliceous sand NF05 and a calcareous filler 0/600 μm were also used for the mortars.

2.2 Cements and superplasticizer

Three types of cement were used for concretes and mortars according with the French standard NF P 15 301:

- a high strength portland cement CPA 55 HTS with low C_3A content,
- a rapid high strength portland cement CPA 55R CP2 with high C_3A content,
- a ordinary blended portland cement CPJ 45 with high C_3A content.

In order to obtain fixed water/cement ratio and workability for the mixtures, a polyvinyl naphthalene sulphonate based superplasticizer was added in various amounts.

3 Tests

3.1 Concretes

From a ordinary concrete mixture containing natural aggregates (NF05 and NC25) and CPJ 45 cement, we obtain by volume substitution of the fine and coarse aggregate, six new concrete mixtures containing recycled aggregates (Table 1).

Table 1**: Concrete **compositions.

Composition kg/m³	*NF/NC*	*NF/CRC*	*CRF/NC*	*CRF/CRC*	*NF/BRC*	*BRF/NC*	*BRF/BRC*
CPJ 45	299	303	300	297	304	301	302
NF05	792	825			790		
NC25	1029		981			1027	
CRF05			677	690			
CRC25		874		885			
BRF05						642	659
BRC25					827		820
Absorbed water		32	45	87	51	44	109
Mixing water	206	212	203	208	199	206	197
Superplasticizer			1.5	3		1.5	3
Apparent density	2325	2245	2205	2170	2170	2220	2090
Slump (cm)	15	15	15	14	15	14	16

Before mixing, the recycled aggregates were wetted near their total free-water absorption capacity. The absorbed water by the aggregates was considered separately from the mixing water, because it does not participate in workability of fresh concrete nor cement hydration. Various amounts of superplasticizer were added in the mixtures in order to maintain a constant water/cement ratio and slump. Compressive strength and splitting tensile strength were measured on moist air cured 0 16x32 cm cylinders at 7 and 28 days age. Expansion and water absorption were measured on underwater cured 7x7x28 cm prisms until three months of age.

3.2 Mortars

A method close to that applied for the concrete mixtures was followed for the preparation of mortars. From a ordinary mortar mixture containing natural fine aggregate (NF05), filler and cement (CPA 55 HTS, CPA 55R CP2 or CPJ 45), we proceed at a volume substitution of the natural fine aggregate using the four recycled fine aggregates (CRF05, CRC05, BRF05, BRC05) previously wetted to their total free water absorption capacity. The cement content of the mortars was fixed at 350 ± 10 kg/m^3. An amount of 1% by cement mass of superplasticizer was added to the mixture. The mixing water was adjusted to obtain a constant workability (4 ± 1 s on the LCL « maniabilimeter » French standard NF P 18 452). This fist series of mortars was comprised of fifteen different compositions.

A second and third series of fifteen mortar compositions were prepared in the same conditions than the first series by adding an sufficient quantity of crushed gypsum from partition-walls in order to obtain 0.5 and 1 .O% of additional SO_3 by mass of dry aggregate.

Compressive strength and flexural strength were measured on moist-air cured 4x4x16 cm prisms at 28 days. Expansion and water absorption were measured on 4x4x16 cm prisms cured in underwater conditions until 3 months of age.

4 Results and discussion

4.1 Characterisation of recycled aggregates

French standards for concrete aggregates were used for the physical and chemical characterisation of the fine and coarse recycled aggregates. The values obtained are shown in Table 2.

Table 2 : Physical and chemical characteristics of recycled aggregates.

Aggregate	*CRF05*	*CRG25*	*BRF05*	*BRC25*	*CRC05*	*BRC05*
Dry density (kg/m^3)	2155	2230	2265	2090	2315	2305
Wet density (kg/m^3)	2290	2360	2410	2245	2385	2430
Absorption coefficient (%)	6.3	5.5	6.3	7.5	3.0	5.4
Total porosity (%)		12.8		21.1		
Fineness modulus	3.2	2.2	3.1	2.7	3.2	3.3
D 50 (mm)	1.2	11.7	1.2	12.5	1.4	1.5
Fine particles (< 80µm %)	5.1	1.3	7.6	1.2	6.7	8.5
SO3 content by mass (%)	0.56	0.38	0.78	0.74	0.38	0.74
Cl content by mass (%)	0.04	0.04	0.03	0.02	0.04	0.02
-C- content by mass (%)	1.28	0.75	0.26	0.14	0.75	0.14

We can observe that the physical and chemical characteristics of recycled aggregates depend on origin of the waste. Recycled aggregates obtained from concrete and hydraulic binder treated materials (CRF05 and CRC25) increase in density as the particle size of the aggregate increase. The inverse is true for recycled aggregates derived from building demolition wastes (BRF05 and BRC25). In both cases, secondary crushing of coarse aggregate seems to improve the physical properties and to increase the dry density (CRC05 and BRCOS). Except the fine recycled aggregate obtained by secondary crushing of reinforced concrete and hydraulic binder treated materials, the absorption capacity of recycled aggregates is higher than the thresholds fixed by the French standards, according to which the absorption coefficient must be lower than 5%.

The sulphate content of aggregates coming from building demolition wastes is higher than that of aggregates coming from reinforced concrete and cement treated materials due to the presence of gypsum impurities observed in the raw materials before crushing. We determined by X ray diffraction that about half the sulphate content of building demolition wastes is present as gypsum. In this case, the sulphate content of concrete and cement treated material seems to be rather important. We surmised that the presence of blast furnace slag as binder in the raw material is the principal reason for this value. In both cases, the sulphate content remains much higher than that fixed by the French standards as the limiting value for concrete aggregates (0.15%). On the other hand, the organic compounds content is more important in the fist type of recycled aggregates because of the presence of some bitumen treated aggregates mixed with the road demolition materials.

4.2 Study of concretes

The mechanical characterisation of concrete mixtures with and without recycled aggregate at 7 and 28 days show that natural aggregate concrete in general provides the higher strengths (Figures 1 and 2). The decrease of strengths by the insertion of recycled aggregate in concrete mixture is lower only when coarse recycled aggregate is used (NF/CRC and NF/BRC). In this case, the decrease varies between 0 and 25%, the mean value is about 15%. On the other hand, when fine recycled aggregate is used, the decrease in strengths varies between 20% and 40% with a mean value about 30%. The measured decrease in strengths is slightly more significant only if fine recycled aggregate is added (mixtures CRF/NC and BRF/NC).

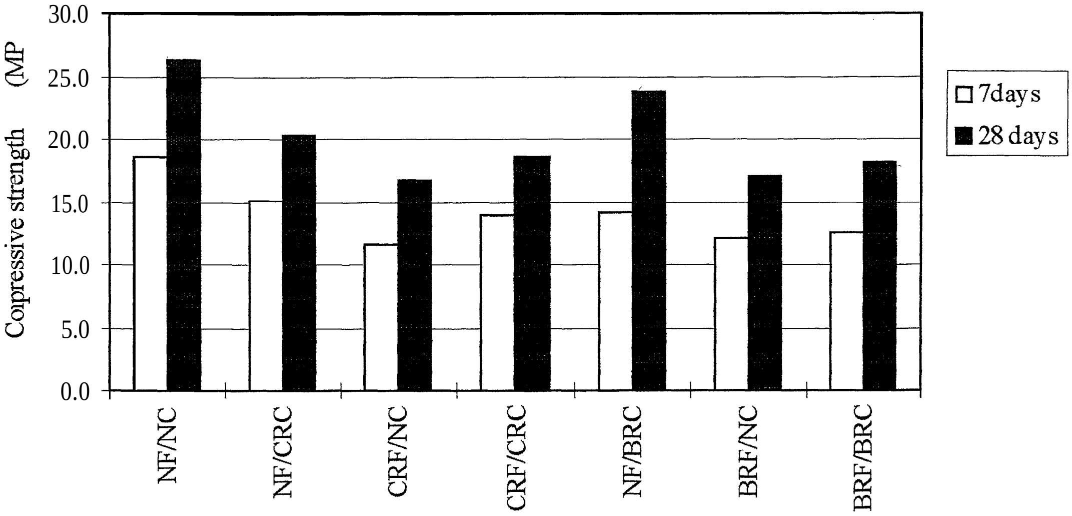

Figure 1 : Compressive strength of concrete mixtures at 7 and 28 days age.

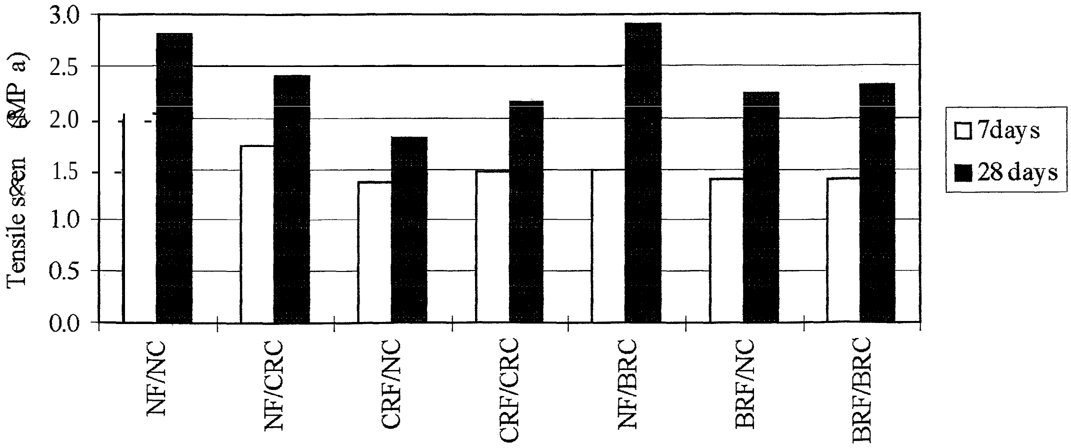

Figure 2 : Splitting tensile strength of concrete mixtures at 7 and 28 days age.

The origin of recycled aggregates does not significantly influence the mechanical strengths. In fact, the fine recycled aggregates provide concrete mixtures with nearly the same mechanical characteristics regardless of their origin. Only the coarse recycled aggregate coming from building recycled wastes, when inserted alone, gives higher quality concrete than that obtained using coarse recycled aggregate derived from recycled concrete structures in spite of its lower dry density and its higher absorption capacity.

In all cases, the presence of small amounts of gypsum in the building recycled wastes has not any obvious disadvantageous effect on mechanical strengths.

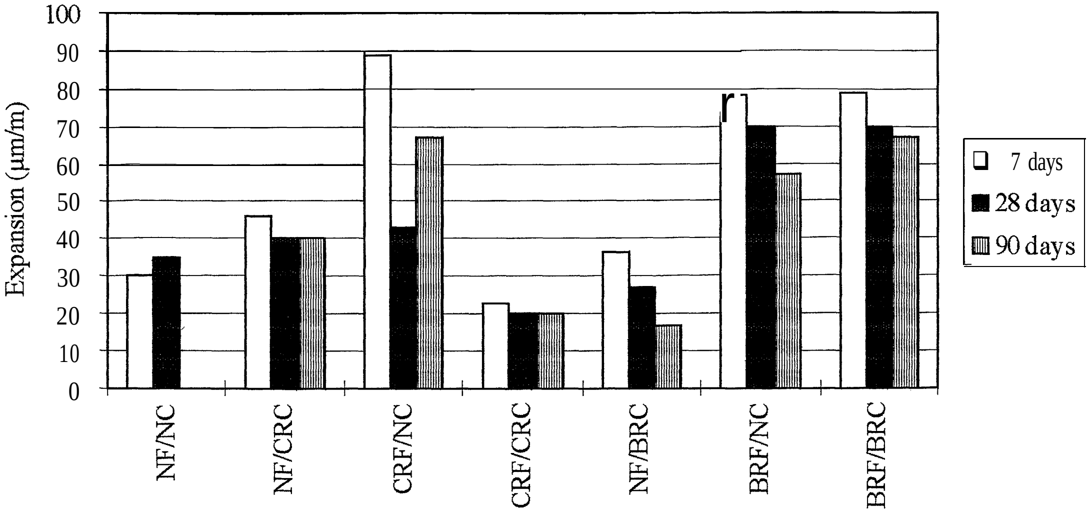

Figure 3 : Expansion of underwater cured 7x7x28 cm prisms until three months age.

The expansion measurements up to 90 days of age on specimens cured in underwater conditions (Figure 3) show that for the different concrete mixtures the values fluctuate between 20 and 90 µm/m. Mixtures with fine recycled aggregate seem to present higher expansion than that measured with natural aggregate or coarse recycled aggregate. But in any case, the expansion values are manifestly lower then 200 µm/m considered as the critical threshold for cracking.

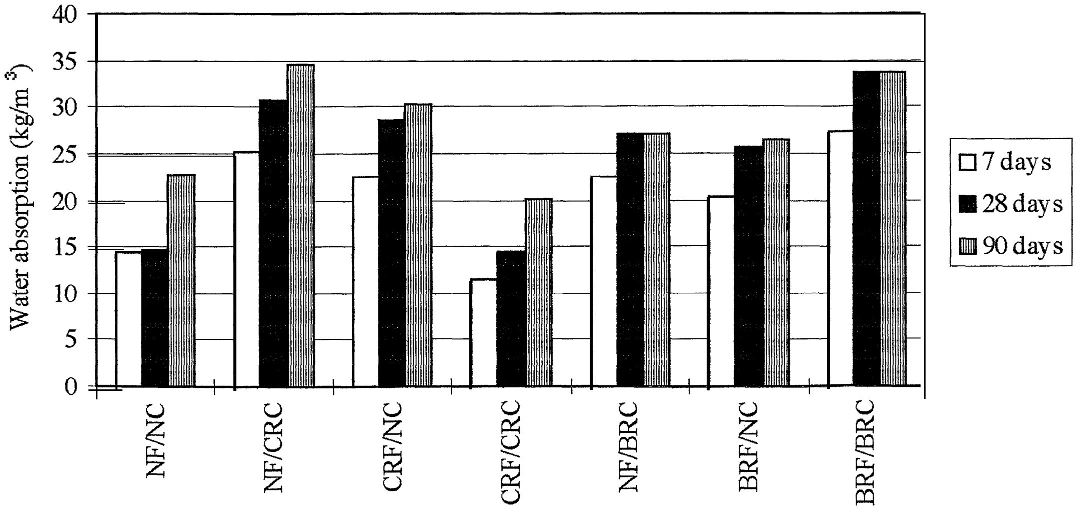

Figure 4 : Water absorption of underwater cured 7x7x28 cm prisms until three months age.

Water absorption of the recycled aggregate concrete mixtures is limited at usual values for concrete, between 10 and 35 kg/m^3, and never reach important thresholds (Figure 4). The values of water absorption are consistent with those of expansion and permit concluding that no significant amount of expansive ettringite is formed in concrete with recycled aggregate when its total sulphate content is limited to 0.8% even if a part of sulphate content (up to *50%)* contained as gypsum. The results also permit to observe that, when recycled aggregates are effectively wetted before -mixing, the resulting concretes are practically saturated and free water absorption remains low.

4.3 **Study of mortars**

Figures 5 and 6 present the variation of the compressive and the flexural strength of mortars as a function of the total sulphate content coming from recycled aggregates and added gypsum expressed as a mass percentage

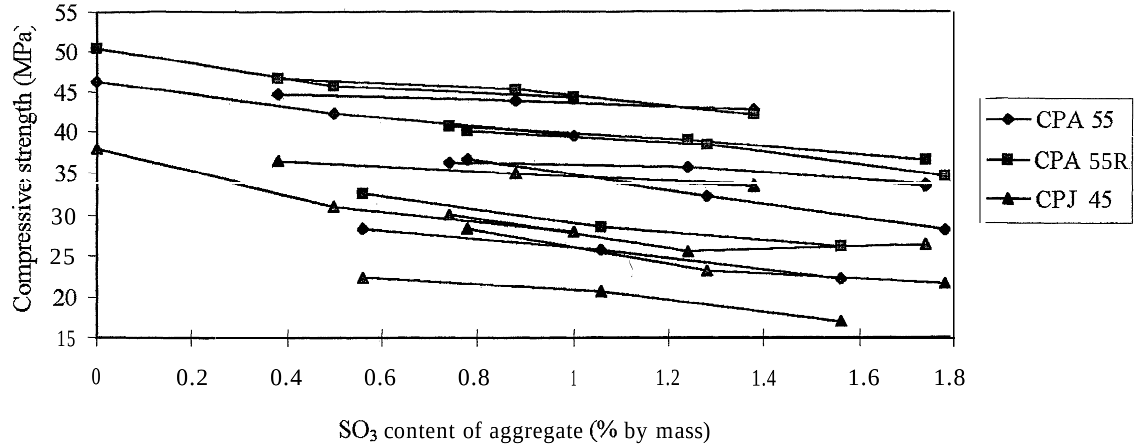

Figure 5 : Compressive strength of mortar mixtures at 28 days age as a function of sulphate content and cement type.

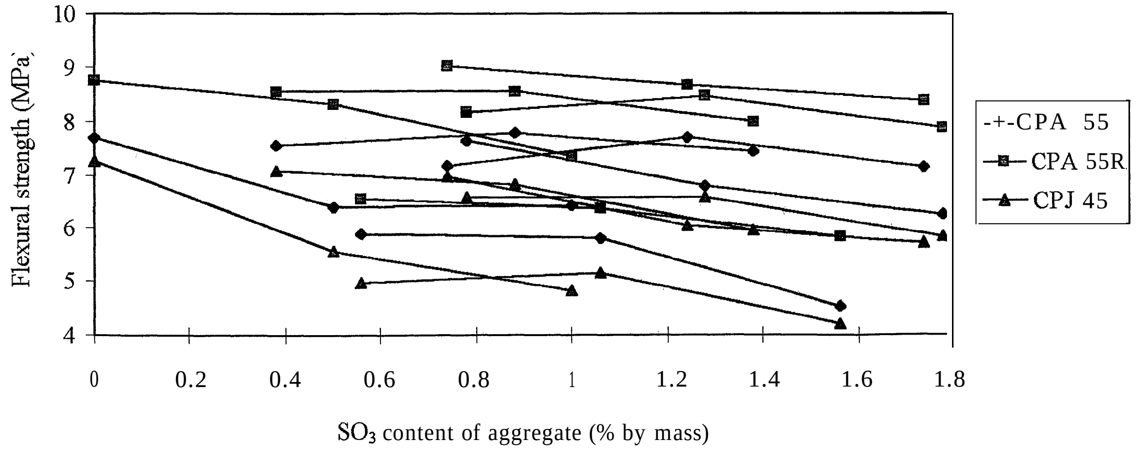

Figure 6 : Flexural strength of mortar mixtures at 28 days age as a function of sulphate content and cement type.

We can observe that the mechanical strength of mortars decreases in proportion to the sulphate content of aggregates. Among natural, sulphate-free aggregate and recycled, high sulphate content aggregate, the compressive strength could be reduced between 20% and 35% and the flexural strength between 10% and 40% depending on the type of cement used in the mix. For a fixed amount of sulphate content the mechanical strengths vary according to the physical properties of the aggregate as it was previously observed in the case of concretes.

The measurements taken at 90 days show that the expansion of mortars is closely correlated with the sulphate content of aggregate (Figure 7). In fact, the critical threshold for cracking of 200 µm/m is reached in the case of blended, high C_3A content cement (CPJ 45) mixed with natural aggregates when the sulphate content is 0.5% by mass. The sulphate content must be higher than 1 .O% if portland cement with low C_3A content (CPA 55) is mixed with natural aggregate. Recycled aggregate mortar expansion is significantly lower than that observed for natural aggregate mixtures. The critical expansion threshold is reached for more than 1.2% sulphate content, except the case of blended, high C_3A content cement (CPJ 45) mixed with secondary crushing reinforced concrete wastes (CRC05), which physical properties are close to those of the natural aggregate.

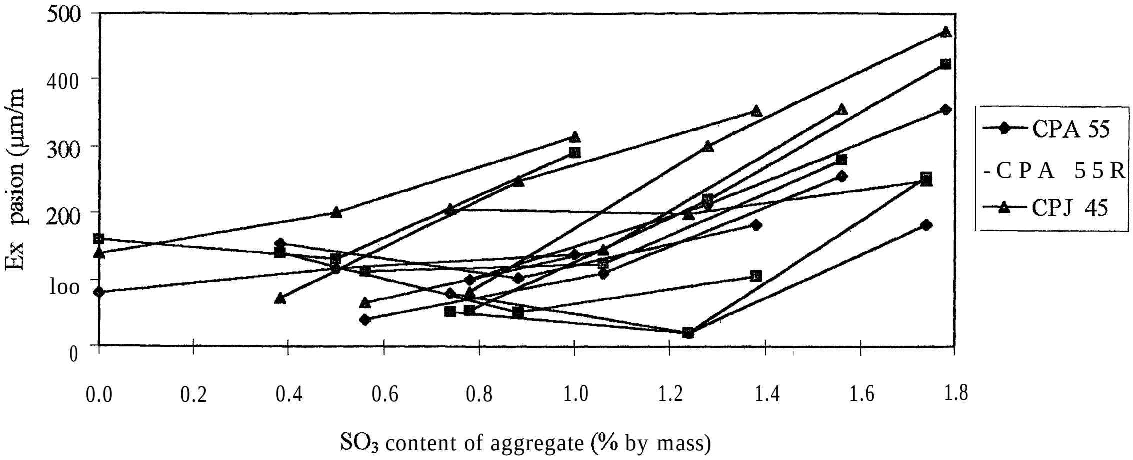

Figure 7 : Expansion at three months age of underwater cured 4x4x16 cm prisms of mortar as a function of sulphate content and cement type.

5 Conclusion

The results obtained enable us to conclude that recycled aggregates, derived from reinforced concrete structures, hydraulic binder treated road bases, masonry and building wastes, contain significant amounts of sulphate (0.3 to 0.8% by mass of SO_3) that are combined in cement hydrates that do not produce significant expansion of concretes or mortars. Mortars expansion becomes critical only when recycled aggregate contains at least 0.5% of additional SO_3 by mass, typically found from gypsum impurities (plasters and partition-walls). The additional sulphate content of recycled aggregate could exceed 1.2% SO_3 by mass when low C_3A Portland cement is used in the mixture. In a general way, gypsum impurities have more effect on expansion of mortars prepared with natural aggregate. On the other hand, compressive and flexural strength of mortars decrease in proportion to the sulphate content.

Recycled Waste Clinker X-ray Structural Analysis

V.S.Gryslov, A.I.Fomenko
Cherepovets State University, Russia

Abstract
Environmental protection policy and economic reasons brought about a sharp rise in the utilization of industrial waste in the manufacture of construction materials. But recycled waste can be a source of allergic, toxic, radioactive, carcinogenic, and other dangerous substances. Besides, technical process of waste recycling can be unstable.

To make the production of construction materials out of waste products ecologically safe and economically reasonable, it is necessary to provide a complete and thorough inspection of the chemical and phase composition of the components and products used. For this purpose an X-ray structural analysis of solid waste and sludge of chemical production has been performed to determine their mineralogical composition, physical and mechanical properties; and on this basis the composition of the raw materials mixture for Portland cement production has been developed.

The chemical composition of the waste was determined through an X-ray spectrum analysis; and the phase composition of both the waste used and cement clinker obtained was determined by using an X-ray diffractometer in the Cu **-** Ka emission range. Physical and mechanical tests of the cement stone samples were conducted in accordance with standard procedures.

X-ray investigations ascertained the possibility of using solid waste of chemical production in the production of construction adhesive materials. It is proved that dumped self-slaked lime, neutralized sludge of lime after chemical purification, and of diethylbenzol production sludge can be used for production of Portland cement of the usual mineral-containing composition.

Composition of the raw materials mixture, data of the X-ray analysis of the mineralogical composition of the clinker obtained, the results of physical and mechanical tests of Portland cement are provided.

Key words: X-ray method, phase composition, diffractography, solid waste of production, Portland cement.

1 Introduction

Natural resources saving and industry blow-out reduction have brought out a sharp rise in amount of the secondary resources in the manufacture of construction materials thus promoting the solving of economy and ecology problems. But in this case allergic, toxic, radioactive, carcinogenic and other harmful substances can get into construction materials and items with the recycled waste. The technological process can be of unstable character. Chemical and phase compositions of initial components and products are to be analyzed totally and thoroughly in order to substantiate the ecological reliability of the recycled waste and to reduce the energy, labor and material expenditure when the production technology is made and construction structures are operated. For this the modern methods of physicochemical analysis are used.

We conducted X-ray structural analysis of solid waste and sludge (taken from dumps and storage ponds of chemical production). On their basis we worked out the compositions of raw material mixture for Portland cement. We determined the composition of the Portland cement and its physical and mechanical properties.

2 Methodology

The phase composition of the investigated waste and of the obtained cement clinker was determined by the DRON-3M X-ray diffractometer (Russia) in the Cu-Kα emission range. The samples for diffiactography were prepared in cuvettes packed with powder.

The chemical composition of the investigated waste was determined by X-ray spectrum analysis with the CPM-25 instrument (Russia).

Physical and mechanical tests of the cement stone samples were conducted in accordance with the working standard procedures in Russia.

3 Discussion

Waste of self-slaked lime, neutralized sludge of lime after chemical purification of water, and of diethylbenzol production sludge can be used as initial raw materials to Portland cement of usual mineral-containing composition. Diffractography of the mentioned waste is given in Fig. 1 and 2. Diffractographies of the tested samples of the self-slaked lime and neutralized lime (fig. 1) show the clear-cut phases of $CaCO_3$, $Ca(OH)_2$, SiO_2. Presence of calcite, calcium hydroxide and quartz phases only indicates the possibility to replace the carbonate rock by the above mentioned waste for production of clinker.

Diffractographies of sludge of lime after chemical purification of water (fig. 2, curve 3) show the phases of $Fe_2O_3, Fe_3O_4, CaCO_3. SiO_2; Ca(OH)_2$ is detected by the reflex 2,63Å. Analysis of diffractographies of diethylbenzol production sludge (fig. 2, curve 4) shows that the main phases of the tested samples are Al_2O_3, Fe_2O_3 and SiO_2. As appears from the phase composition investigations the mentioned waste can be used instead of argillaceous rock containing aluminum oxide, silica and ferric oxide.

Thus raw materials mixture for clinker production can be made out of the investigated waste without using natural resources.

Average chemical composition of the investigated waste is given in Table 1.

Calculation of the raw materials mixture to manufacture the Portland cement of usual mineral-containing composition has been performed on the basis of the average data of the chemical composition of all raw materials components in accordance with method [1,2]. Since industrial waste characterized by inconstant mass ratio of the components is used as raw materials calculations were done by a computer in order to provide the conformity of chemical composition of the raw materials mixture to the preset mineralogical composition of the produced clinker. Calculated data of seven compositions of the raw materials mixture are given in Table 2.

Chemical composition of the obtained samples of the raw materials mixture was determined by the calculation in accordance with data of Table 1 and Table 2 and was monitored by the X-ray spectrum analysis. Comparative characteristic of the raw materials mixture is shown in Table 3.

The mineralogical composition of the clinker was calculated in accordance with the data of chemical composition of the raw materials mixture. Comparative characteristic of the preset and calculated mineralogical composition of the clinker is given in Table 4.

To determine correspondence of the clinker mineralogical composition produced from the waste to the calculated data the raw materials mixtures of the compositions given in Table 2 were calcined in a tube electric furnace under 1,300 C temperature during 30-40 minutes. After grinding of the obtained clinker up to specific surface of 3,000 cm^2/gram its phase composition and its physical-mechanical characteristics were determined.

Diffiactographies of the obtained cement (fig. 3) show the phases of tricalcium silicate C_3S, dicalcium silicate C_2S, tricalcium silicate C_2S, dicalcium silicate C_2S, tricalcium aluminate C_3A and tetracacium alumo-ferrite C_4AF. Minerals which are not specific for Portland cement of usual mineral-containing composition were not found in the investigated samples. Presence of CaO phases (reflexes 2.39; 1.69; 1.46 A), SiO_2 (reflexes

4.29; 3.37; 2.28 A) and AL_2O_3 (reflexes 5.58; 4.87; 3.195 Å) indicates the low temperature conditions of the calcination of the raw materials mixture caused by characteristics of a laboratory electric furnace.

Results of the physical-mechanical tests given below testify also to advisability of the analyzed waste use for Portland cement production of usual mineral-containing composition which meet demands of the standard.

Normal thickness of the cement paste, %	25
Density, G/cm^3	3.2
Setting time, hrs - minutes:	
the beginning	1-20
the end	7-45

Strength (after steaming)
at the age of 28 days, MPa:

when bending	**4 . 6**
when compressing	**32.6**

4 Conclusions

Conducted investigations have ascertained the chemical and mineralogical composition of the dumped and unused solid waste of chemical production.
It is proved that the main components of waste are carbonate and calcium hydroxide, silicon, ferrite and aluminum oxides.
It is suggested to use the investigated waste as raw materials for production of Portland cement instead of argillaceous and carbonate rocks.

New Information Service
Environmental Declaration of Building Products

M. Salmi
The Building Information Institute, Helsinki, Finland

As a part of “Environmental technology in construction” The Finnish Building Information Institute has developed, in co-operation with industry and Technical Research Centre of Finland, a model of environmental declaration of building material and products. R&D has been carried out in co-operation with the Swedish information dealer Svensk Byggtjänst.

The model of environmental declaration consists of following components

- Product identification
- Service life
- Energy consumption in production and during the service life
- Consumption of raw materials
- Emissions like greenhouse gases, acid rain gases and emissions causing oxidants
- Solid wastes
- Recycling of product and packages
- Healthy at work and assembly and indoor climate.

Model will be tested by creating environmental declarations for some 40 building products (trade names). Declarations and the procedure will be described in the presentation.
Keywords: Ecology, product information, sustainable development.

1 Background

Consumers and decision makers are today conscious about sustainable development and ecology. This is the situation also in construction sector although we know that building has only limited effect on the development of our Globe. So there is a need for new building information about the impacts on biodiversity, harmful emissions and usage of natural resources.

We should remember, that ecology is only one aspect of sustainable development. The others are economical possibilities, social acceptance, political possibilities and cultural traditions. All these aspects should be taken into consideration when making decisions to build a new house or repair an old one.

Therefore its is important, that new, "ecological" information is stored and served as a part of the over all building information. No new organisations are needed, building information centres can take care of information services for sustainable building.

2 R&D activities in the Building Information Institute

The Finnish Building Information Institute has carried out series of state-of-art -studies of sustainable building design in Sweden, Norway, Denmark, Germany, The Netherlands, England and USA. As a result of these studies the Institute has published **Ecological Criteria for Building Design in Finland.** The publication is available in English and free of charge at our homepage www.rts.fi. My presentation is totally based on these criteria.

Ecological criteria are meant to be the basement for our R&D-activities (research and development) concerning both renewal of RT-Building Design Guidelines and creating Environmental Declarations for building products based on Life Cycle Analyses (LCA).

The Institute's R&D is partly financed by TEKES (Technology Development Centre of Finland) through Environmental Technology in Construction programme (1995-99), see www.tekes.fi. A short description of our projects is in www.rts.fi.

3 Recommendations for design guidelines

It is necessary to include environmental information in publications used in project management and design. In client and designer task lists, a checklist is needed of the major questions to be decided in different phases of the project, when the goal is sustainable building. The owner of the building is responsible for defining the level of quality of the project, environmental impacts considered. In publications guiding design and construction quality,(i.e.RYL 90; General Quality Requirements of Construction Works), specification guidelines, design guidelines (RT information sheets), and product information (RT product sheets) more detailed information is called for.

Environmental information about building, and tools for using the information are needed by

- owners with a responsible interest in their own project,
- designers who have to present alternatives to the initiator of the project,
- producers, importers, and exporters, in order to direct their sales according to an environmentally conscious demand,
- construction firms seeing environmental consciousness as a marketing advantage, and
- building branch information services, in order to disseminate information further.

Manufacturers carry the major responsibility of providing information about the environmental impacts of construction products. They have, or should have, information concerning the origin of raw materials of construction products, the impacts caused by their acquisition, their composition, the consumption of energy during production, and the characteristics of emissions caused. The same requirement concerning environmental information applies to prefabricated products, because producers hold the initial information.

The situation is different, when it comes to in-situ building components defined in the specification: no single producer can be expected to provide information about the future *component* (about particular supplies, yes), because the component will only be created on site. Environmental information concerning product components must be calculated based on information about supplies and work processes. The information is to be found in the corresponding design guideline (RT information sheets).

Concisely, information distribution needs to be developed in the following manner:

- product-specific information is provided by the manufacturer in product sheets;
- information concerning prefabricated products is provided by the manufacturer in product sheets;
- information concerning typical components is provided on the basis of calculations in instruction sheets or guidelines.

Information about the environmental impacts of construction is to be concatenated as follows: products and work processes –> typical components –> typical spatial units. A need to update is created by product development, as the chain of production or a working process is improved in order to win a competitive position. Complementary information is needed, when new solutions for building components gain general acceptability, and when new types of spatial units become common.

Compiling environmental information about building in a database that makes comparisons possible means ongoing development activity. Compiling such information provides a challenge for developing products and work processes to become ever more competitive in order to decrease the environmental changes caused by construction, both locally and globally.

4 Product information in building design

4.1 Life cycle analyses and new product information

The result of a life cycle study as well as information concerning the functional qualities of products can be used as a basis of product choice during building design.

An entire building or a mechanical component as well as a construction product can be the subject of a life cycle study.

Because of the abundance and openness to interpretation of information describing the environmental qualities of a product, the conditions of a well-developed utilisation of life cycle study results in the gradual development of design solutions would be significantly improved, if the information were applied in consensus between the producer or component provider and the designer.

When the basic criteria of environmental impacts potentially useful in guiding solutions and choices in the design process are examined, at the moment it is a question of resources and harmful emissions. When it comes to construction products, production processes on the one hand and the service life of products on the other hand have an immediate impact on the creation of environmental stresses.

In building design, the basic intellectual condition for using a result of a life cycle study is that

- the environmental qualities of products are assessed and made known, and
- the distribution and updating of information is organized.

The alternative to be recommended, when it comes to environmental assessment and information distribution concerning products, is that the studies be made by producers. The recommendation is based on the assumption that such a study can then best be grounded in the knowledge about the realised material and energy flows, and, additionally, the study can easily function as a basis for decision-making in process development.

The quality requirements concerning the information about the environmental characteristics of construction products should be set so that the information can be considered useful initial information in a design process.

4.2 Proposal for principles of environmental declaration of a building product

The following is a proposal for the basic principles of assessment of the environmental qualities of construction products. When the basic principles of assessment are agreed upon, it is mainly a question of the limits of the study, arriving at the factors mentioned above, determining the quality of the information.

1. Environmental characteristics are assessed on the basis of a life cycle study, following the methodology presented in the proposal ISOIWD 14041, Life Cycle Inventory Analyses. The following particular principles are observed during the study:
2. The numerical result of environmental impacts is calculated based on the material and energy flows created, starting with the acquisition of raw materials, energy raw materials, and auxiliary materials, and up to the end of product service life. The material and energy flows caused by the unavoidable maintenance operations in order to ascertain the service life will be included. The creation of infrastructure, renovation of production, accidents, and environmental impacts created by workforce will be excluded.
3. Energy resources will be classified as non-renewable and renewable. The energy content of raw materials will be included and can be listed separately. Harmful emissions will be classified to those attributed to air, water, and land. The burning of wood will not be considered to cause carbon dioxide emissions. Occupational health, indoor air, odour, and noise impacts will not be considered in a life cycle study.

4. Land use as a use of resources will not be included in the numerical end result. Environmental impacts caused by the acquisition of raw materials can be estimated qualitatively.

5. The quality of the information is described by its technological, chronological, and geographical coverage, and by an estimate of its representatives. The basic information consists of the annual average values of the material and energy flows of the system under study. In addition to an annual value, information must be acquired about the potential range of fluctuation of the value.

6. If more than one product is created in the process, environmental impacts will be ascribed on the basis of natural causality, or a physical parameter like mass, chosen with reason. Environmental impacts will not be ascribed onto secondary products of little value.

7. The result of a life cycle estimate will be presented in relation to the product service life indicated by the producer. For a life cycle study, a building and a building component must have a proposed service life. In a service life estimate of building components and products included in them, only technical damage will be taken into account. A life cycle study will include an estimate of the material and energy flows necessitated by maintenance.

8. The estimated numerical end result of environmental impacts will not include the material and energy flows during a potential re-use or recycling of the product. In a life cycle study, only the actual practice will be taken into account. If the re-use of the demolition products has been organised, some of the environmental impacts will be allocated to the next round of use. Environmental impacts will not be allocated to a recycled product, if it is of little value compared to the original one. The use of wood products as fuel after their service life will be taken into account in the energy balance.

9. "Savings" in energy consumption occasioned by the exceptional thermal characteristics of a product will not be included in the numerical end result. The impact of the exceptional thermal characteristics of a product can, however, be estimated numerically, and indicated separately.

10. The result will be given as per mass and a suitable functional unit.

11. The best comparable unit in a building is a space. The environmental characteristics of a space will be derived from building components, which consist of certain products. In comparing products, building products consisting of materials and supplies will be discussed as functional units. Equivalent products will be defined as follows:

- function,
- composition, and
- proposed service life.

4.3 Environmental characteristics as part of the attributes of building products

Systematic lists of attributes are available for organising information in the field of building. Internationally significant lists of attributes have been devised by CIB (Conseil International du Batiment) and IS0 (International Organization for Standardization) (CIB Master List 1993, IS0 6241). On the basis of the CIB and IS0 results, a Finnish master list of attributes has been created, with the following areas of information:

- identification
- description
- composition

- agents, requirements, properties, and
- additional information.

Among properties, the attribute of environmental properties is listed. According to the master list, energy expended in manufacturing and the proportion of non-renewable and renewable natural resources used will be indicated in the description of environmental properties, and re-use and recycling characteristics, demolition, or returning to the manufacturer after use will be reported.

In the following, an expanded definition of the attribute of environmental properties will be proposed:

> In the description of environmental properties, the consumption of renewable and non-renewable raw materials for energy, and the production of harmful emissions per functional unit will be indicated, on the basis of a life cycle analysis (raw materials acquisition, manufacturing processes, transportation, construction, use and maintenance, recycling or final destination). A functional unit is a space or construction product with a predicted service life at point of use.

4.4 Service life and the environmental impacts of products

One way of approaching environmentally conscious solutions in building material development and choice is to distribute the environmental damages caused by resource use and harmful emissions over a period of time longer than previously, i.e. to attempt to extend or ascertain the technical service life of products. Attempts toward a service life extension of construction products can be made besides

- product development, also by
- developing quality assurance of products and construction processes, and
- developing use and maintenance directions of materials and products.

In order to take into account the significance of such procedures in environmental impact assessment and product choice based on environmental properties, service life assessment methods must be included in life cycle analyses of products. In order for manufacturers to be able to give service life estimates, and for the estimates to be comparable, uniform methods should be agreed upon for the estimation procedures of products of various types, and for the argumentation expected for indicating the service life estimates of products.

Significant advances have been made in recent years in service life estimating and planning by ISO, CIB, RILEM etc.

In the environmental assessment of construction products, it is important to be able to utilise the existing knowledge of technical damage assessment for the service life assessment of selected functional units.

5 Environmental declaration of building products in Finland and Sweden

Environmental declaration is a part of normal product declaration. It's target group is a planner or designer in a building process or supplier of building products.

The Building Information Institute and VTT from Finland and Svensk Byggtjanst Ab and Instutet for Byggekologi from Sweden have agreed to start co-operation in producing environmental declarations according the following principles:

1. Environmental declarations will be based on the information produced by life cycle analysis or equal studies that fullfill the quality criteria of ISOIWD 14041 and national recommendations such as those produced in Sweden by Byggsektorns Kretsloppsrad.
2. Environmental declarations will be published in Finland and in Sweden so, that Building Information Institute, in co-operation with VTT, will certificate the Swedish declarations to be valid in Finland and Byggtjänst, in co-operation with Institutet för Byggekologi, will certificate the Finnish declarations to be valid in Sweden.
3. Environmental declarations will include the following information both in Sweden and in Finland.

   1. Identification information of the product
      - Trade name
      - EAN-Code
      - Classification
      - Service object
      - Product dimensions

Analysis of the performances of concrete components made with recycled aggregates

P. Dessy, C. Badalucco, L. Bignami, F. Cantoni, L. Morfini, L. Nironi, S. Palmieri, A. Strini
CNR ICITE, San Giuliano Mil.se, Italy

Abstract

The paper presents the first phase of a research programme that investigates the utilization of recycled aggregates coming from crushed concrete rubble in the production of precast blocks. In particular, the paper reports the results of the characterization of the aggregates and of the performance evaluation of concrete specimens in which different percentages of recycled aggregates are contained. The testing of the precast blocks will be carried out during the second phase of the study.
Key words: characterization, concrete performance, recycled aggregates.

1. Objectives and research phases

The aggregates resulting from the processing of concrete rubble in a crushing plant located in Corbetta (Milan, Italy) have been analyzed, and their compliance with the Italian standards about the use of aggregates in medium strength concrete has been verified. In particular, first the characterization of the aggregates has been carried out and then different series of concrete specimens have been prepared following a mix design procedure which optimized the use of these aggregates, with respect to what is known about their performances from international studies. The research was aimed at finding out indications both for the utilization of these aggregates in precast concrete and for the improvement of rubble crushing technologies. In detail, it has mostly focused on the following:

- grading curve of the concrete mixtures: the fine fraction of recycled aggregates, which is believed to be the most problematical, has been replaced with natural sand;
- water/cement ratio of the concrete mixtures, taking into account the water absorption properties of grains;
- mix design.

The analyses have been carried out according to the test procedures and acceptance limits envisaged by the Italian standards on natural aggregates (UNI 8520 series) and to the exposure classes envisaged by prEN 206 on fresh and hardened concrete. These standards are an useful reference also for recycled aggregates, awaiting the European standard approval.

The UNI 8520 series proposes three categories of acceptance limits for aggregates. Each category corresponds to specific final uses, as mentioned in Table 1:

Category **A**	Category B	Category C
use in concrete with $R_{bk} \geq 30$ MPa or exposed to aggressive actions	use in concrete with R_{bk} up to 30 MPa	use in concrete with $R_{bk} \leq$ 15 MPa

Table 1: UNI 8520 acceptance limits

The relationship between requirements for concrete and enviromental conditions is expressed by the exposure classes envisaged by prEN 206 "Concrete - performances, production and conformity", which relate the properties of the aggregates to the final use. The most important property for the aggregates, envisaged by prEN 206, is their density which is regarded as an effective indicator of their global quality.

2. Characterization of recycled aggregates

The analysis of the properties of recycled aggregates is an important step in order to formulate their best use. Therefore, two fractions of aggregates with grading 0/7 mm and 0/16 mm have been characterized. The following paragraphs show the test results.

2.1 Composition and grading curve of the aggregates

The studied aggregates include the following material fractions, expressed by weight: "natural" coarse aggregates (gravel): 75%; tile: 7,5%; old mortar 14%; sand (grading < 0,5 mm): 2%; polluted aggregates: 1%; bitumen: 0,62%; expanded clay: 0,13%; vegetable lightweight lumps: 0,02%. The percentages expressed by volume are similar. Table 2 and Table 3 show the grading curves of the fractions 0/7 mm and 0/16 mm.

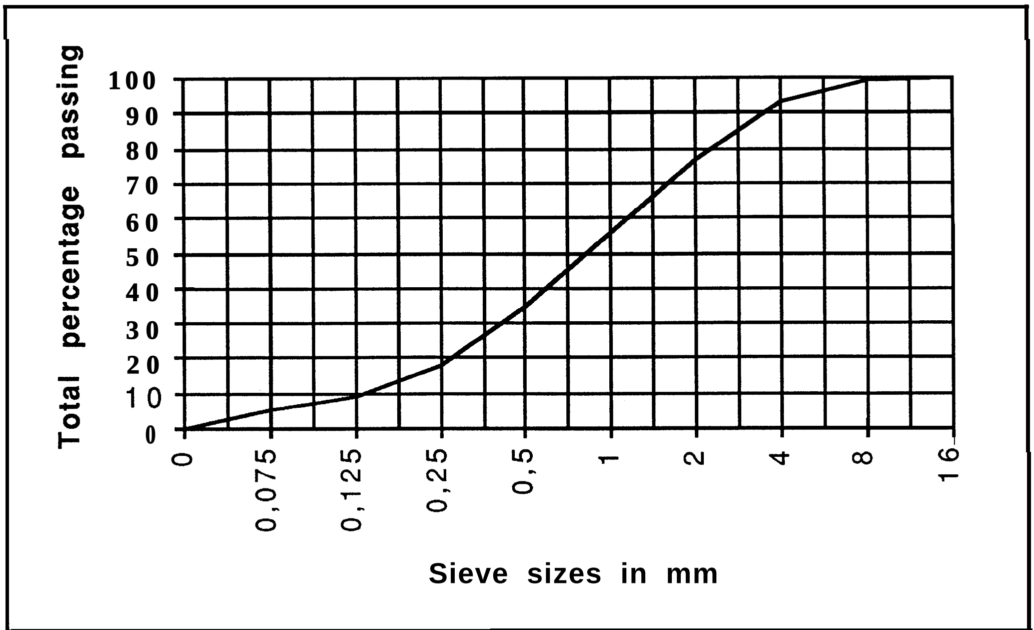

Table 2: Grading curve of aggregates 0/7 mm (UNI 8520-5)

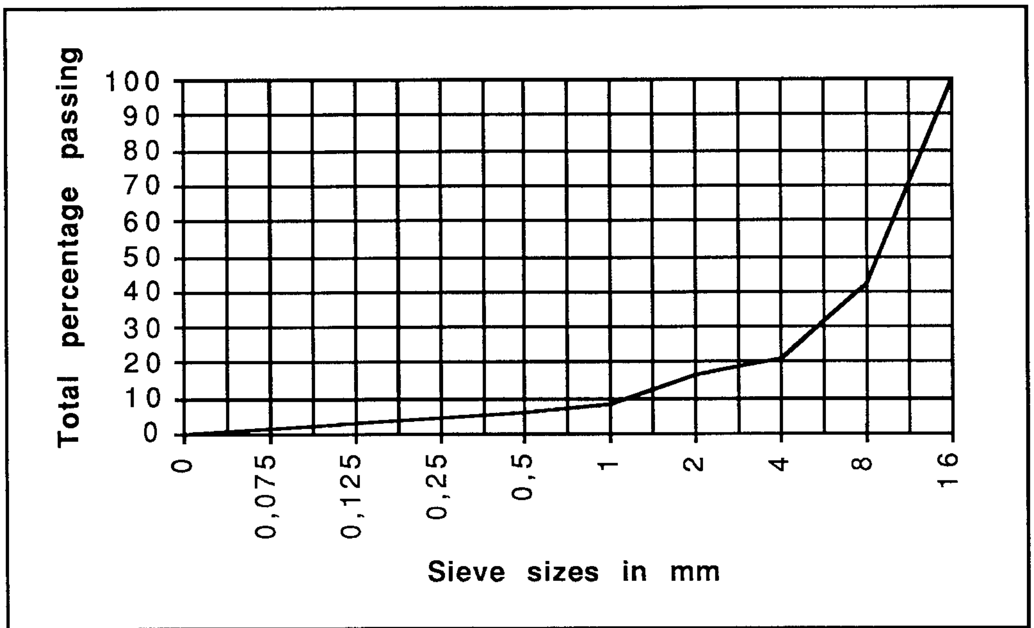

Table 3: Grading curve of aggregates 0/16 mm (UNI 8520-5)

2.2 Fineness Modulus (UNI 8520-5)

The Fineness Modulus (MF) individualizes with a single numerical parameter the particle size distribution as a whole. The analyzed aggregates have the following fineness modulus:

- Fraction 0/7 mm: 4,08
- Fraction 0/16 mm: 6,97

2.3 Determination of soluble sulphates (UNI 8520-11 Method A)

The sulphates contained in the aggregates normally originate from gypsum but only soluble sulphates are reactive and, if present in big amounts, may cause damage to concrete because of their swelling inside the material.
Test results set the fine fraction slightly beyond standard acceptance limits, while coarse fraction falls within those values. Table 4 shows the results.

Average Soluble Sulphates content % (SO3)		Acceptance limits (UNI 8520-2)
Fraction 0/7 mm	0,2439 %	$SO_3 \leq 0,20\%$.
Fraction 0/16 mm	0,1923 %	

Table 4: Soluble sulphates content

2.4 Sand equivalent and methylene blue value of fine aggregates (UNI 8520-15)

Sand equivalent (ES), which expresses the volumetric percentage of clean sand on the whole sedimented aggregate, is used as an indicator for detecting an excessive presence of slime clayey material, which is noxious for concrete. If ES value is under 90, it is advisable to define the methylene blue value (VB) which, unlike ES, distinguishes between slime clayey material and very fine ground stony material useful for concrete.
The ES test has been carried out only for the 0/7 mm fraction because it is envisaged only for fine aggregates; it is however important to specify that the analyzed recycled aggregates cannot actually be considered as fines: in fact, the standard regards as fines

only those aggregates more than 95% of which passes through the 4 mm sieve; on the contrary, only 93,57% of the analyzed fraction (0/7 mm) passes through the same sieve.
Test results set the analyzed aggregates within the acceptance limits (see Table 5).

ES	Acceptance limits (UNI 8520-2)	VB (cm/g)	Acceptance limits (UNI 8520-2)
86,63	Category A: ES ≥ 80	0,32	Category A: VB ≤ 0,6 cm3/g of fine
	Category B: 70 ≤ ES ≤ 80		Category B: VB ≤ 1,0 cm3/g of fine
	Category C: ES = 70		

Table 5: Sand equivalent and methylene blue value of fine aggregates

2.5 Determination of organic impurities content of fine aggregates (Colorimetric determination - UNI 8520-14)

Organic impurities can give rise to different problems such as reduction of cement hydration, worsening of the dimensional instability of concrete when subjected to alternate dry/wet cycles, trapping of excessive air amounts in concrete, which reduce its mechanical properties.
As envisaged by the standard, three single specimens have been analyzed: they have shown a clearer coloring in comparison with a reference solution.
Such results widely fall within the acceptance limits.

2.6 Density and water absorption of fine aggregates (UNI 8520-13) and of coarse aggregates (UNI 8520-16)

The density and water superficial absorption test has been carried out with the pycnometer method for the fine aggregates, while for the aggregates with diameter larger than 4 mm (to be used in concrete) the utilized method was hydrostatic weighing. Table 6 reports the results.

	Fraction 0/4 mm	Fraction 4/7 mm	Fraction 4/16 mm	Acceptance limits (UNI 8520-2)
Mvess (kg/m3)	22143,3 (kg/m3)	2238,2 (kg/m3)	2334,61 (kg/m3)	//
Mvsa (kg/m3)	2394,9 (kg/m3)	2361,28 (kg/m3)	2452,88 (kg/m3)	Category A: MV≥2400(kg/m3) Category B: MV≥2200(kg/mc)
Water absorption %	8,15 %	5,43 %	4,68 %	Category A: ≤ 5% Category B:≤ 10%

Mvess = Real average density with dried particles
Mvsa = Real average density with water saturated dry surface conditions
Table 6: Density and water absorption

Fractions 0/4 mm and 0/7 mm are included in Category B of UNI 8520-2, while fraction 4/16 is included in Category A; it seems that the inclusion of fine grains in Category B

can be ascribed to the larger percentage of cement paste which coats them and gives rise to a density reduction. As a matter of fact, the international standard trend is to limit the possible cement mortar contents in recycled aggregates by defining an acceptance limit of density for them.
The analysis has shown that recycled aggregates have a high water absorption value compared to the set limits for natural ones. The mix design hereafter proposed has considered this chatacteristic.

3. Performance evaluation of concrete

A series of concrete specimens have been prepared using the analyzed recycled aggregates in order to verify the mechanical properties of concrete. In particular, the following mixtures have been compared:

- a mixture prepared with 100% of recycled aggregates;
- a mixture in which the fine fraction has been replaced with natural sand;
- a mixture prepared with 100% of natural aggregates ("witness mark"), which represents a reference mark for the performance evaluation of concrete made with recycled aggregates.

The mix design and the mixture procedures have considered both the international experiences on the matter and the results of the previous characterization phase: the definition of the mix design has in particular consisted in the search of the best possible grading curve and in the study of the water/cement ratio. Moreover, the recycled aggregates have been pre-wet before the preparation of the mixture in order to obtain saturated dry surface conditions. As far as other characteristics of the concrete mixing process are concerned (slump, type of cement, casting time, etc.), they have been kept constant in order to better outline the different performances of concrete made with recycled aggregates. The cement used is type 42,5 R UNI ENV 197 - 1 CEM II.

3.1 All recycled mixture (AR3)

It is the mixture produced with 100% of recycled aggregates; in order to define the best admeasurement of the two available fractions, a numerical method based on Fineness Modulus has been applied. The proportions thus defined have then been adjusted, by approximation, to Fuller optimum curve. In fact, the available granulometry had proved to be too rich in fine fraction (2 mm sieve), which is very critical for recycled aggregates; the proportion of the two fractions has been therefore corrected by reducing the fine fraction percentage.
The mixture which most approaches the Fuller optimum curve is made with 35% of 0/7 mm fraction and 65% of 0/16 mm fraction.

Mixing procedures

The aggregates have been let saturate for 15 minutes in the concrete mixer with 8,25 litres of absorption water and some revolutions have been applied; then the traditional procedure has been carried out. The main characteristics of the mixtures are the following:

- Water/cement ratio: 0,77 • Slump: 4 cm • Casting time: 12 minutes

Table 7 reports the compressive strength values:

AR3 Characteristics	***fresh concrete***	***48 hours***	7 ***days***	28 ***days***	90 ***days***
Average density (kg/m3)	2232,30	2192,49	2148,52	2170,67	2117,33
Average compressive strength (MPa)	//	//	21,95	28,59*	31,48

*Mean Quadratic Deviation among the 28 days Compressive Strength values: 0,746

Table 7: Compressive strength values of AR3

3.2 Recycled mixture with natural fine fraction (RSF2)

In this mixture the recycled sand fraction with a diameter less than 2 mm, which is considered the most critical for this kind of material, has been replaced with natural sand in the proper proportion. In order to compare the results, the grading curve has been calculated so as to be as similar as possible to the one of the previous mixture: the fine fraction replaced with the natural sand represents the 41%.

Mixing procedures

In this mixture, a pre-wetting phase has been carried out only for the recycled fraction (15 minutes with 11,5 litres of absorption water). Main characteristics:

- Water/cement ratio: 0,69
- Slump: 3 cm
- Casting time: 11 minutes

Table 8 reports the compressive strength values:

RSF2 ***Characteristics***	*fresh concrete*	***48 hours***	7 ***days***	28 ***days***	90 ***days***
Average density (kg/m3)	2270,61	2231,31	2217,48	2188,15	2186,67
Average compressive strength (MPa)	//	//	26,50	32,48*	38,10

*Mean Quadratic Deviation among the 28 days Compressive Strength values: 0,472

Table 8: Compressive strength values of RSF2

3.3 All natural mixture (NT2)

The "witness mark" mixture has been prepared with natural aggregates only. A granulometric assortment as similar as possible to the one of the recycled aggregates mixtures has been calculated; this mixture has been taken as a reference mark for the comparison of the different hardened concrete types.

To define the appropriate mix design it was necessary to analyze the grading of the available natural fraction (0/3 mm, 3/7 mm 7/15 mm). The calculation of the fineness modulus has allowed to identify, by approximation, the correct proportions of the different fractions which could give rise to a curve as similar as possile to the optimum theoretical one also used for the recycled mixtures: fraction 0/3 mm: 30%; fraction 3/7 mm: 35%; fraction 7/15mm: 35%.

Mixing procedures

For this natural aggregates mixture no pre-wetting procedure has been carried out. Main characteristics:

- Water/cement ratio: 0,66
- Slump: 4 cm
- Casting time: 10 minutes

Table 9 reports the results of compressive strength values:

NT2 Characteristics	*fresh concrete*	**48 hours**	7 ***days***	28 ***days***	90 ***days***
Average density (kg/m3)	2320,98	229 1,46	2274,07	2256,59	2259,56
Average compressive strength (MPa)	//	//	29,39	37,71*	39,72

*Mean Quadratic Deviation among the 28 days Compressive Strength values: 0,911

Table 9: Compressive strength of NT2

4. Conclusions

The analysis of the test results allows to draw up a few comments.

First of all, the evaluation of the fitness for use in concrete of recycled aggregates has resulted into compressive strength values much higher than the minimum required by law for reinforced concrete structures (D.M. LL.PP. n. 19 -1996), that is to say a characteristic resistance R_{bk} of 15 MPa (the Compressive Strength values found at 28 days are assimilable to R_{bk} owing to the small mean quadratic deviations). Even though the same law does not allow to use recycled aggregates in structural concrete, the present study points out that this is not only an acceptable alternative from a technical point of view, but also a promising application, given the environmental advantages that this recycling technology offers: reduction in the exploitation of non-renewable resources and in the production of Costruction and Demolition (C&D) waste to be disposed of in landfill.

Secondly, the comparison between the performances of the three different mixtures has allowed to confirm the assumptions based on the existing writings on the matter, which outlined the effects of certain parameters (water/cement ratio and concrete density) on the hardened concrete compressive strength. With reference to this, the variation of compressive strength values in connection with the variation of water/cement ratios and concrete density values (Table 10) has been examined.

	R_{bk} 28 ***days*** *(MPa)*	*w/c* ***ratio***	***density*** *(kg/m³)*
100 % Recycled (AR3)	28,59	0,77	2170,67
41% Recycled (RSF2)	32,48	0,69	2188,15
100% Natural (NT2)	37,71	0,66	2256,59

Table 10: Main characteristics of three mixtures

NT2 mixture bears the highest compressive strength value obtainable with the selected cement type and slump (37,71 MPa), whereas AR3 mixture bears the lowest value in the set of three for the three mixtures prepared; ultimately, RSF2 mixture (with 41% of recycled aggregates) lies approximately in the middle between the two extremes.

As far as the different water/cement (w/c) ratios only are taken into account, a correlation between their increments and the correspondent reduction of compressive stregth values in the three mixtures stands out. This correlation, though, is much clearer between AR3 and RSF2 mixtures than between RSF2 and NT2. See the variations (A) in w/c ratios :

- $A_{Rbk(RSF2-AR3)}/A_{RbkTOT}$= 42,6%; $\Delta_{a/c(AR3-RSF2)}/\Delta_{a/cTOT}$= 72,7%
- $A_{Rbk(NT2-RSF2)}/A_{RbkTOT}$= 57,3%; $\Delta_{a/c(RSF2-NT2-)}/\Delta_{a/cTOT}$= 27,3%

In fact, the increment of w/c ratio between RSF2 and AR3 is relevant and is likely to be the cause of the contemporary reduction of R_{bk}: if this is the case, then the possible reason for the reduction of compressive strength appears to be the presence in RSF2 of recycled aggregate fine fraction (grading < 2 mm) with its high water absorption value, already addressed by international studies as the origin of the decrease in compressive strength values of concrete.
However, if the NT2 versus RSF2 characteristics are looked into, a much less relevant difference between the respective WC ratios can be observed, while the decrement (A) in the compressive strength values is still comparable to the one already noticed between AR3 and RSF2. The fact that w/c ratios in RSF2 and NT2 are very alike leads to expect the water absorption properties of recycled aggregates contained in RSF2 (41% of the total aggregates by weight and with a grading >2 mm) to be much more similar to the water absorption properties of the natural ones than in the case of AR3 versus RSF2. Therefore, there would appear to be, in this case, another factor responsible for making the compressive strength decrease: the concrete density (∂), which gives a direct measure of the internal presence of voids. In fact, the available data for density decrement are:

- $\Delta_{Rbk(RSF2-AR3)}/\Delta_{RbkTOT}$= 42,6%; $\Delta_{\partial(RSF2-AR3)}/\Delta_{\partial TOT}$= 20,3%
- $\Delta_{Rbk(NT2-RSF2)}/\Delta_{RbkTOT}$= 57,3%; $\Delta_{\partial(NT2-RSF2)}/\Delta_{\partial TOT}$= 79,6%

As previously assumed, the average density values are much more different between NT2 and RSF2 than between RSF2 and AR3, which induces to believe that what is responsible for the further decrement in compressive strength between NT2 ad RSF2 is actually the larger number of voids inside the concrete, since the decrement cannot be entirely put down to the slightly different w/c ratios between NT2 and RSF2.
All in all, the good compressive strength values found for recycled concrete need to be confirmed in the near future through further research dealing with the problem of quality constancy of recycled aggregates over the time, given the non-homogeneity of C&D waste processed in crushing plants. The next phase of the study will look into the possibility of utilizing recycled aggregates in the production of precast concrete blocks.

Life Cycle Impact of Floor Coverings: A Model for the Contribution of the Usage Phase

J. Paulsen
Division of Building Materials, Department of Building Sciences, Royal Institute of Technology, Stockholm, Sweden

Abstract
Compared to other industrial products, building products have a significantly longer service life. When applying LCA methodology to building products, one obvious problem is how to take into account the environmental impacts from the usage phase. In this paper, the usage phase is analysed and a proposal for a model is given based on a division of the usage phase into three parts representing frequent, periodical and upgrading maintenance. The model is applied to floor coverings and some preliminary characteristics and results are presented and discussed.
Keywords
LCA, Service life, Environmental impacts, Floor coverings, Usage phase.

Life Cycle Impact of Floor Covering: A Model for the Contribution of the Usage Phase

1. Introduction

Life cycle assessment (LCA) methodologies have developed rapidly during the recent years. The technique is to a large extent used and developed for environmental assessments of short life products from industrial sectors such as packaging and vehicles. LCAs are frequently used for assessment of materials and components either for the purpose of comparing different alternatives or for proposing improvements. The methodologies have to a large extent been adopted into the building sector and have given much valuable input. But, one obvious distinguishing property of building materials and components is their significantly longer service life compared to other industrial products. Therefore, the usage phase might be of major importance in the building sector from an environmental point of view.

Unfortunately, it can be problematic to take the usage phase into account in a product or component LCA. The problems are connected to the lack of information on this phase (Paulsen & Lundblad 1996). To give an overview of the problem, the life cycle is here divided into three main steps:

1) Raw material extraction and production of a product or a component.
2) Maintenance of a product or a component during the usage phase.
3) Waste treatment or recycling of the product or component.

According to LCA methodology, the analysed object has to be assigned a functional unit and the environmental impacts expected from this unit. This means information and data are needed for the whole life cycle of the object (cradle to grave). Normally, for building products, the information and data range is available to the first part of the life cycle, step 1, extraction of raw materials and production of the object, also called cradle to gate inventory. This stage is therefore normally quite simple to handle.

To collect data on the usage phase (here called step 2), information is needed on for example the application of the object in the building, its expected lifetime, maintenance ‘methods and intervals, auxiliary products and local conditions. Without this type of data/information, it is almost impossible to include the usage phase in an LCA for building products.

To analyse stage 3, waste treatment or recycling, information is needed concerning contents of hazardous materials in the product together with knowledge about techniques and market for recycling and development of techniques for waste treatment. Here scenarios normally are based on the assumption that today’s techniques are used in the future. It does not give the same reliability as in step 1, but possibly a reasonable estimation of the possible environmental impacts.

In summary, the first and the last stage of the life cycle can be regarded as less complicated to analyse while the stage in the middle, the usage phase, is more complicated to analyse since the environmental impacts from this stage are difficult to predict. However, one reason for being concerned about the usage phase for building products is the long-term perspective. It could possibly turn out to be the step with the largest environmental impact.

A number of LCAs have already been carried out on long-life products from the building sector, despite the problems with lack of information concerning the usage phase (Erlandsson et al 1994, Jönsson 1995, Erlandsson 1994). In general, two different methods have been used to circumvent the problems. It has either been assumed that the environmental impact from the usage phase is zero, or a comparative analysis has been carried out with the assumption that the environmental impacts from the usage phase are the same for the analysed products. In this case, they cancel out each other.

A method to take this step into account might enable the choice of more favourable products, auxiliary materials or maintenance methods, and at the same time give feedback to manufacturers. Only considering impacts from the first and third step could lead to sub-optimisations, and thereby failure to reduce the total environmental impacts.

One possible solution to this problem is to divide the LCA into the three different steps (1,2 and 3) mentioned above. For steps one and three, an LCA can be carried out with the most commonly used LCA methods. On the other hand, step two has to be analysed in a less traditional way, due to lack of information. The assumed condition is that the product type is known, but not the exact conditions for the usage phase. However, for some product groups it might be possible to predict the most important parameters causing environmental impacts in the usage phase, even though the extent of these impacts can be hard to estimate for each parameter. The needed information is normally unknown until the application of the product is known. However, if the most probable application and circumstances can be reduced to a limited number of possibilities, maybe different scenarios can then be carried out and the expected quantities and extents estimated for each scenario.

In this paper, an inventory of the usage phase for floor coverings is carried out to illustrate this approach and to examine the extent to which environmental impacts can be predicted in the usage phase.

2 LCA-model for floor coverings in the usage phase

The suggested model refers to a scenario in Sweden where the floor coverings are placed in large buildings and maintained by a contracted cleaner, assuming that an industrial cleaning machine is used. No specific floor covering type is selected.

The emphasis is on the external environment. Human health and indoor environment will not be included.

2.1.Determination of environmental impacts from the usage phase

For this kind of flooring, it can be assumed that the maintenance consists of three maintenance stages (Lidström 1997, Franzén 1997), which are frequent, periodical and upgrading maintenance respectively. The aim of the frequent maintenance is to remove dirt and maintain a healthy and aesthetic indoor environment. The aim of the periodical maintenance is to satisfy the technical function of the floor e.g. an easily cleaned surface. For some types of floor coverings, this can be achieved by periodical polishing. Other types of floors do not need any periodical maintenance at all. The aim of the upgrading is to improve an older floor covering to a level where both the aesthetic and technical functions are satisfactory. The upgrading is similar to the action performed for periodical maintenance, but is likely to be more extensive, e.g. non-periodical polishing or grinding of linoleum, wood or stone flooring. This is done only a few times during the whole usage phase, in some cases never. The suggested model in this paper is an overview model where the type of floor covering is not yet decided. With specified type of floor covering, the importance of environmental impacts from periodical and upgrading maintenance should be easier to estimate.

It is suggested that the environmental impacts for floor coverings during the usage phase are a combination of impacts from maintenance products and the maintenance methods in all three maintenance stages mentioned above. This gives six parameters to determine (see table 1).

Table 1	Maintenance stages		
Source of impacts	Frequent	Periodical	Upgrading
Impacts from products	I_{pf}	I_{pp}	I_{pu}
Maintenance methods	I_{mf}	I_{mp}	I_{mu}
Totally from the stage	I_f	I_p	I_u

The total environmental impact I_{tot} in the usage phase can then be calculated as shown in equation 1a or 1b:

$$I_{tot} = I_{pf} + I_{pp} + I_{pu} + I_{mf} + I_{mp} + I_{mu} \quad (1a)$$

$$I_{tot} = I_f + I_p + I_u \quad (1b)$$

For all the environmental impacts one square metre can be used as the functional unit.

2.2 Determination of environmental impacts from the frequent cleaning

The environmental impacts from the frequent maintenance I_f can be expressed as shown in equation 2:

$$I_f = \int_0^T \left[i_{pf}(t) + i_{mf}(t) \right] dt \quad (2)$$

where $i_{pf}(t)$ and $i_{mf}(t)$ are the time-depending momentary environmental impacts per time unit from frequently used maintenance products and methods.

However, this study concerns floor coverings placed in larger buildings and maintained by a contract cleaner. Therefore, the variation over time for daily cleaning can be considered minimal, at least during one year (Lidström 1997). Assuming that the same products and methods are used during the whole usage phase, the yearly environmental impacts will be constant. This is not quite accurate but one possible way to give an estimate of the total environmental impacts. With this assumption, equation 2 can be simplified to equation 3:

$$I_f = N^* (I_{pfy} + I_{mfy}) \qquad (3)$$

where N is number of years for the maintenance period, I,, and I,, are the yearly environmental impacts from maintenance products and maintenance methods respectively, in the case of frequent cleaning. Assuming that only one cleaning product is used, and that the environmental impacts from the maintenance method are caused by energy use, I, can be calculated from equation 4 and I,, from equation 5:

$$I_{pfy} = E_{pf} * A_{pf1} * n_f \qquad (4)$$

$$I_{mfy} = E_{el} * n_f * A_{fel1} * \eta_1 + E_{ew} * n_f * A_{fw1} * AT * c_w * \eta_2 \qquad (5)$$

where

E_{pf}	Environmental impacts from one litre or kg of the used cleaning agent.
E_{el}	Environmental impacts from one MJ electricity, primary energy.
E_{ew}	Environmental impacts from one MJ energy produced to heat water.
A_{pf1}	Amount of cleaning agent for one cleaning.
A_{fel1}	Amount of electrical energy required for one time of cleaning (MJ).
A_{fw1}	Amount of water required for one cleaning (litre).
n_f	Number of times the floor is cleaned during a year.
η_1	Efficiency for electricity production and machinery.
η_2	Efficiency for energy production to heat water.
AT	Increase in temperature when heating water for cleaning.
c_w	Heat capacity for water (0,0042 MJ/kg*°C).

2.3 Determination of environmental impacts from the periodical cleaning

The environmental impacts from the periodical maintenance I, can be expressed as shown in equation 6 also assuming that the same products and methods are used during the whole usage phase, for each periodical maintenance occasion:

$$I_p = N * (I_{ppy} + I_{mpy}) \qquad (6)$$

where I, and I_{mpy} are the yearly environmental impacts from maintenance products and maintenance methods respectively, in the case of periodical cleaning. Here it has to be assumed that several maintenance products are used. At least one product is needed to prepare the floor surface and another to treat and protect the surface for the future. Furthermore, it is assumed that the environmental impacts from the maintenance method are caused by energy use. Thus, the I,, can be calculated from equation 7 and the I_{mpy} from equation 8:

$$I_{PPY} = n_p * \sum_{k=1}^{k=K} E_{pp,k} * A_{pp1,k} \qquad (7)$$

$$I_{mpy} = E_{el} * n_p * A_{pel1} * \eta_1 + E_{ew} * n_p * A_{pw1} * AT * c_w * \eta_2 \qquad (8)$$

where

$E_{pp,k}$ Environmental impacts from one litre or kg from maintenance product No. k.

K Number of maintenance products used for periodical maintenance.

$A_{pp1,k}$ Amount of maintenance product k for one periodical maintenance.

A_{pell} Amount of electrical energy required for one periodical maintenance .

A_{pw1} Amount of water required for one time of periodical maintenance (litre).

n_p Number of times the floor is periodically maintained during a year, (can be less than 1).

2.4 Determination of environmental impacts from the upgrading

The upgrading maintenance can be expressed in almost the same way as the periodical maintenance assuming that the impacts are the same for each occasion, but here there is a difference in the time perspective. The upgrading can be expected to be done only a few times during the whole usage phase. Therefore, it is not appropriate to express the environmental impacts on a yearly basis. Equation 9 shows the environmental impacts from the upgrading maintenance.

$$I_u = m * (I_{pu1} + I_{mu1}) \qquad (9)$$

I_{pu1} and I_{mu1} are the environmental impacts from maintenance products and maintenance methods respectively, related to one upgrading maintenance. The factor m is the number of times this can be expected to be done during the whole usage phase.

Products like abrasive paper and other grinding materials can be taken into consideration, but are excluded in this study, assuming they cause a negligible environmental impact. Therefore, the I_{pu1} and I_{mu1} can be calculated similarly to equation 7 and 8. This is done in equations 10 and 11:

$$I_{pu1} = \sum_{h=1}^{h=H} E_{pu,h} * A_{pu1,h} \qquad (10)$$

$$I_{mu1} = E_{el} * A_{uel1} * \eta_1 + E_{ew} * A_{uw1} * AT * c_w * \eta_2 \qquad (11)$$

where

$E_{pu,h}$ Environmental impacts from one litre or kg from maintenance product No. h.

H Number of maintenance products used for upgrading maintenance.

$A_{pu1,h}$ Amount of maintenance product No. h for one upgrading maintenance.

A_{uel1} Amount of electrical energy required for one upgrading maintenance.

A_{uw1} Amount of water required for one upgrading maintenance (litre).

3. Predictability of input data

In table 2, the parameters from the suggested model are listed together with a suggestion as to where the information should be collected.

Table 2

Type of parameter	Parameter	Where to collect information
Length of usage phase	**N**	Recommendations and feedback from practice
Amounts of products	A_{pf1}, A_{pp1k}, A_{pu1h}	Contracted cleaner
Amounts of electricity	A_{fel1}, A_{pel1}, A_{uel1}	Contracted cleaner
Amounts of water	A_{fw1}, A_{pw1}, A_{uw1}	Contracedt cleaner
Maintenance intervals	n_f	Recommendations
	n_p	Recommendations
	m	Recommendations
Environmental impacts from maintenance products	E_{pf}	Cleaning-agent producers
	$E_{pp,k}$	Manufacturer
	$E_{pu,h}$	Manufacturer
Environmental impacts from energy production	E_{el}	Swedish average
	E_{ew}	Swedish average
Other factors	η_1, η_2	Swedish average
	AT	Estimation of Swedish average

For some parameters, Swedish averages can be used allowing quite acceptable estimates. This concerns environmental impacts from energy production, efficiency factors for water heating and temperature increase needed for water in the different maintenance steps.

With regards to environmental impacts from the products, it is important to know firstly which products are used, and secondly what environmental impacts they have. Therefore, it is important to have LCAs or LCIs (life cycle inventories) carried out on the most commonly used products. Products with the largest market share could be selected and also some environmental labelled products which could serve as benchmarks.

Other key factors are the amounts of products, electricity and water involved. Here it is possible that larger cleaning companies have standard machinery where it is possible to estimate the electricity use and efficiency, and the amount of water for one square metre of floor (Franzén 1997). The dosage of cleaning agents for the frequent maintenance will probably depend strongly on the type of products used. Amounts of products for the periodical and upgrading maintenance are likely to be more predictable when the type of floor is specified.

Regarding maintenance intervals, the specification of type of floor and premises can be used to facilitate the determination. Here, experience from real-estate owners could be useful together with statistics from the Swedish building stock. Predicting the life time of a floor covering can be very difficult (GBR 1996, Langowski 1997). Actually, it is impossible to give an exact answer about the expected life time, because it depends on a number of independent factors, which together determine the total life time of the floor covering.

4. Discussion

It could prove to be possible to give a reasonable estimate of the environmental impacts in the usage phase for floor coverings in Sweden for special types of premises. However, it strongly depends on the predictability of the maintenance method and intervals. Furthermore, an extensive data base on maintenance products has to be created. As mentioned above, the lifetime of floor coverings is difficult to predict and needs further research. Still, a recommendation can be used in a scenario.

The suggested model introduced in this paper has to be tested in a number of case studies to reveal which parameters are most important. To carry out an LCA normally causes problems in deciding on limitations. The question is what to include and what to exclude in an analysis, as it is impossible to take everything into account. This suggested model may have to be extended or reduced depending on which parameters prove most important.

As a final point, it is important to remember that a product LCA is normally performed in the production stage with good knowledge of this step. In contrast, an inventory on the usage phase and waste/recycling stage contains many uncertainties about long lived products. Therefore it seems reasonable to divide the presentation of the LCA into three parts, production, usage phase and waste treatment/recycling, in a transparent way.

Autoclaved aerated concrete for construction in hot regions

H. Almudhaf and F. Al-Ragom, Kuwait Institute for Scientific Research, Kuwait

Abstract

The common construction system used in Kuwait is a frame structure consisting of reinforced heavy concrete beams and columns with reinforced floors and roof slabs. Walls are constructed by filling the skeleton with masonry blocks. This type of construction is the dominating system used in the Arabian Gulf Countries and is even used in one and two story residential buildings.

Autoclaved aerated concrete (AAC) was introduced in the mid 1980's as an alternative material that can provide both the structural and heat resistance characteristics required. AAC is produced as masonry units to be constructed in RC skeleton construction, in addition to reinforced AAC panels which are constructed as a homogeneous AAC precast system.

This paper reviews the performance of buildings constructed using AAC. The structural and thermophysical properties are presented. Patterns of energy consumption of a typical building were developed using a computer building simulation program and energy savings calculated. Finally the findings are reflected on the national scale as environmental aspects of the production process, building performance and power supply requirements.

Keywords: Autoclaved aerated concrete, building performance, energy consumption, hot regions.

1 Introduction

Concrete frame structure is the common construction system in Kuwait. Such a system consists of a skeleton of reinforced concrete beams and columns with reinforced concrete floor and roof slabs. Walls are constructed by filling the skeleton with masonry blocks. This type of construction is even used in one and two story residential buildings. Load bearing wall construction is rarely used. The most commonly used masonry blocks are made of solid heavy concrete with a low compressive strength. With such practices, the unit weight of wall construction could reach 380 kg/m^2 while the unit weight of roofs reaches up to 440 kg/m^2.

Kuwait's summer lasts from April to October; it is hot, with maximum temperature reaching 50 °C or more in shade; and it is dry, although relative humidity can reach 60% in late summer and 90% in autumn and winter. Solar radiation is high; in late summer it may reach 1,100 W/m^2, and there are more than 230 days of clear sky in a year. Winter temperatures arc in the range of 10-20 °C. Rainfall, which occurs between October and May, is sparse; it may range from as little as 50 mm to more than 300 mm. Average wind speed is 3 m/s. The prevailing wind is northwesterly and is dry, since it passes over a large region of desert; the secondary wind is southeasterly and moist, since it comes in from the Arabian Gulf.

Electrical energy consumption is governed by the need for space cooling, to the extent that air-conditioning peak power consumption in Kuwait during the summer reaches 70% of the total generated . The excessive demand for air-conditioning is attributed to the extreme ambient air temperature during the summer. Though a large proportion of the increase in demand has been caused by the steady increase in per capita consumption, an important factor contributing to the increasing consumption rate is the government's subsidy to consumers, reflected by the low price of the electric unit. This is as low as 2 fils/kWh, representing 5% of the actual present cost. Another factor is the erroneous assumption that, due to the wide availability of low-cost fuel in oil-rich countries, like Kuwait, power generating costs are trivial. In fact, the production, transmission and distribution costs of electric power place a heavy burden on the state budget, in light of the world energy crisis and such factors as the import of equipment and technical skills.

2 Energy conservation measures

In response to the rapid increase in electricity demand, conservation measures had to be introduced and enforced to curtail the energy requirements in buildings. The Kuwaiti Ministry of Electricity and Water (MEW) code of practice for energy conservation in buildings [1] sets several requirements to limit the peak loads for space cooling. The peak electrical load for residential buildings is set at a maximum of 65 W/m^2. To meet such requirements, the code presents target minimum standard for energy conservation measures. Table 1 specifies maximum thermal transmission allowed for walls and roofs of heavy construction. To comply with the Kuwaiti energy code, exterior heavy walls should include a layer of 5 cm thermal insulation material while a 7 cm thermal insulation material should be embedded within heavy roof sections.

Table 1. Maximum Thermal Transmission (U-Value) Allowed for Walls and Roofs of Heavy Construction.

	Maximum Overall U-Value	
	BTU/h ft^2 °F	W/m^2K
Wall	0.10	0.57
Roof	0.07	0.40

3 Autoclaved aerated concrete

The enforcement of strict limits on the thermal resistance for exterior walls gave way to the introduction of autoclaved aerated concrete blocks as an efficient material that can provide the necessary thermal insulation properties without the use of specific thermal materials. Autoclaved aerated concrete was developed at the end of the 1920's in Sweden [2]. Cement and lime, together with siliceous fine materials such as sand, slag or fly-ash and water, are used as raw materials. A small amount of aluminum powder is added. A chemical reaction between the aluminum powder and the lime increases the volume by forming air-filled cells. The product is autoclaved for 10 hours at 10 atm at 180 °C. The autoclaving initiates a reaction between the calcium and silica to form calcium hydrosilicates.

Autoclaved aerated concrete has a low bulk density and a particularly favorable ratio between material strength and bulk density. The lower bulk density consequently causes a lower consumption of raw materials which is shown by the way of comparison to other building materials in figure 1 [3]. Furthermore, autoclaved aerated concrete posses remarkable possibilities for waste processing and recycling. Since the material can be easily cut and sawed with simple tools making it possible to reduce the waste in the site to a minimum. A main feature in that is the recycling processes used in typical AAC plants.

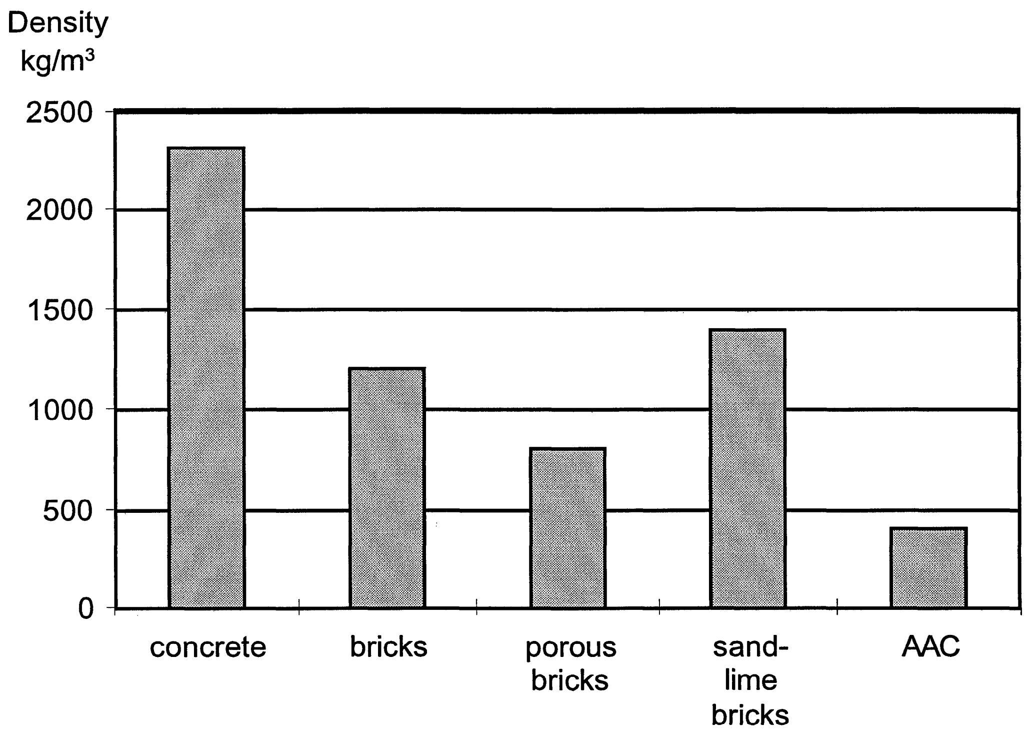

Fig. 1 Consumption of raw materials in the production of building materials [3].

Autoclaved aerated concrete, being a light weight material, provides a useful thermal inertia because it possesses an advantageous combination of mass, thermal conductivity and specific heat properties. This means that autoclaved aerated concrete can reduce the extremes of internal temperature compared with buildings made of lighter structures (which have minimal thermal capacity) or heavier structures (providing less thermal insulation). During the warm season, the thermal inertia of an autoclaved aerated concrete roof of normal thickness works in such a way that inside the building the rise of temperature due to solar radiation is delayed by as much as 6-12 hr, counted from the time of the day when the solar radiation is at its maximum. After this time the effect of radiation decreases considerably. The roof then emits its accumulated heat during the cooler part of the day. Consequently, the capacity of the power plant required for heating or cooling (and the energy required for their operation) can be reduced. Figure 2 presents a typical dynamic heat flow in which there is a time variation of the exterior surface temperature, but the interior temperature is kept constant by heating or air-conditioning [4].

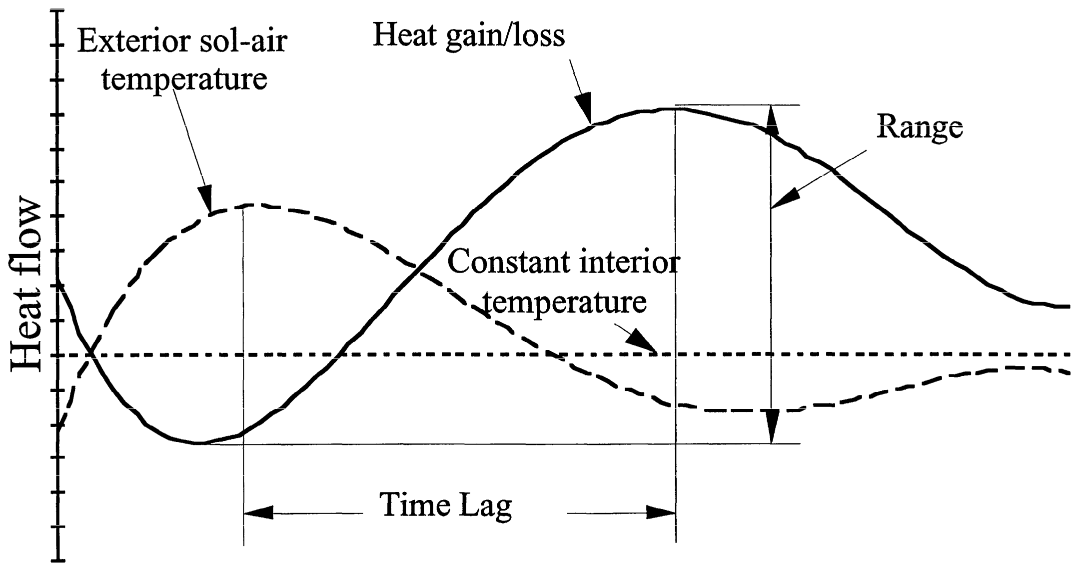

Fig. 2 Dynamic heat flow [4].

4 Use of autoclaved aerated concrete in Kuwait

Autoclaved aerated concrete blocks are produced in Kuwait in densities ranging from 450 to 600 kg/m^3. The most common size is 60 x 20 x 20 cm. A special 2-mm thick epoxy glue mortar is used to bond the blocks. With its superior thermal insulation properties, a 20 cm thick autoclaved aerated concrete block wall finished with sand cement rendering and sand lime brick can satisfy the Kuwaiti energy code without the addition of a thermal insulation material.

Precast autoclaved aerated concrete panels are also produced for use in roof wall construction. Typical panel size is 25 x 60 x 200 cm with densities reaching up to 900 kg/m^3. A building constructed using autoclaved aerated concrete panels precast system in the building envelope (roof and walls construction) will maintain the advantages of this type of construction to its full extent when compared with the mixed system currently used in Kuwait where autoclaved aerated concrete blockwork is integrated with a heavy reinforced concrete frame structure.

5 Energy consumption patterns

To analyze the effect of energy consumption, a typical Kuwaiti house was considered. The technique employed to predict the thermal performance of the building used computer based building simulation. Figure 3 shows a typical hourly power consumption for the building constructed using conventional heavy weight wall and roof systems for both insulated and uninsulated cases. On the national scale, power consumption have been increasing steadily as shown in figure 4. It should be noted that the drop in 1991 was due to the interruptions induced by the Iraqi invasion during 1990/91.

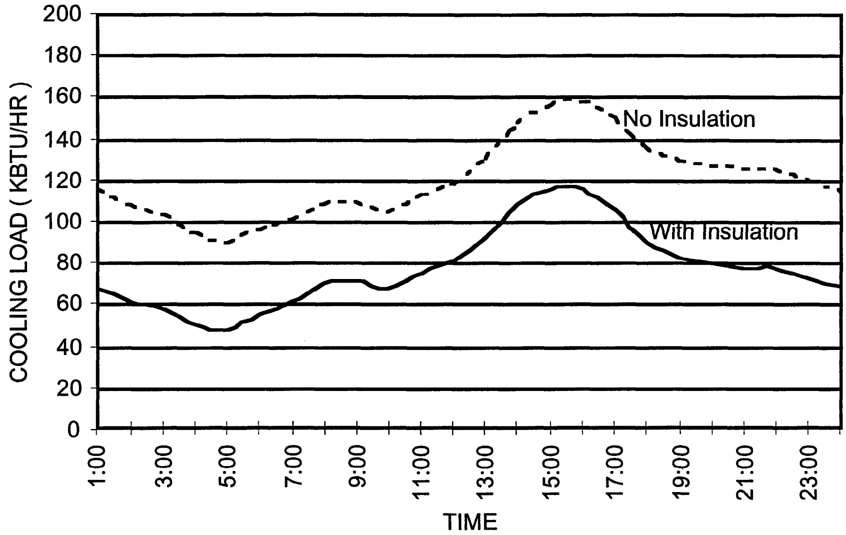

Fig. 3 Typical hourly power consumption for a Kuwaiti house.

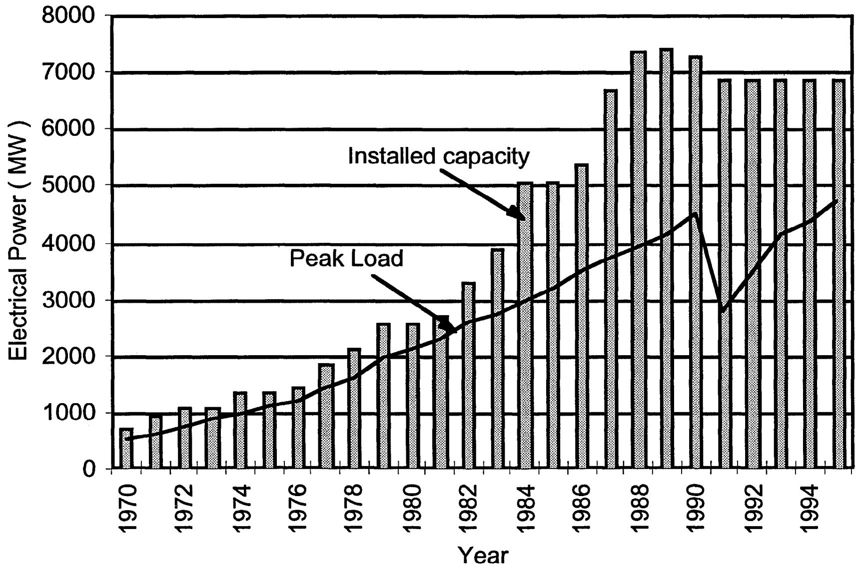

Fig. 4 Peak power consumption compared to installed capacity in Kuwait [4].

As discussed earlier, buildings constructed using autoclaved aerated concrete are expected to posses different hourly power consumption pattern in which the peak load is expected to shift compared to the traditional heavy weight structures. As autoclaved aerated concrete is considered lighter in mass, it is predicted that the peak load will occur with a less time lag compared to heavy structures. Hence if the overall peak load for the residential sector, which represents 85% of the total number of power consumers in Kuwait [5], occurs on 4:00 pm, the amplitude of such peak load can be reduced by shifting to other construction systems that can maintain a different peak time, in this case autoclaved aerated concrete.

Assuming a target of 30% of residential buildings constructed using autoclaved aerated concrete, expected to maintain a time lag that is 2 hours shifted from the 4:00 pm current peak time, will reflect on a peak load shaving of around 260 MW on the national scale. Further demonstration analysis and studies are required to determine the exact reduction in the national peak load as conservatively expressed earlier. It should be noted that achieving such percentage of residential buildings that utilize autoclaved aerated concrete construction is not a difficult goal. A direct sector that can be targeted is the governmental housing program that is expected to deliver around 1000 housing unit annually.

6 Discussion and recommendations

Autoclaved aerated concrete is a building material which can be produced with low consumption of raw materials some of which are recycled waste. It offers remarkable heat insulation characteristics while maintaining strength requirements.

The light weight and thermal inertia properties of the material provides a useful energy consumption pattern that, when integrated with other buildings of different mass, can contribute effectively in peak load reduction on power plants.

A national plan need to be developed for the optimum distribution of buildings as heavy, medium and light weight construction. The optimization will contribute further into reducing the electric peak load consumption. To encourage such shift in the construction industry, incentives need to be developed. Such incentive may be lower prices of the electric unit or defining a lower thermal resistance requirements for light weight walls and roofs. Some authorities have recognized the thermal inertia contribution, such as the California Energy Commission which defines lower R-values [3].

Assessment of the environmental compatibility of concrete admixtures

R. Gälli and M. Ochs
BMG Engineering AG, Schlieren, Switzerland
U. Mäder
Fachverband Schweiz. Hersteller von Betonzusatzmitteln FSHBZ c/o Sika AG,
Zurich, Switzerland

ABSTRACT

Concrete and mortar adrnixtures are substances added to concrete or mortar with the aim of influencing their fresh and hardened properties by their physical or chemical action For example, in the case of fresh concrete the flow, the cohesiveness and the setting behaviour are controlled but also the hardened concrete properties such as strength, impermeability, shrinkage, or frost thaw resistance can be positively influenced by the use of a concrete admixture.

Because of their low dosage concrete admixtures play a subordinate part in the multicomponent system concrete. Nevertheless it is our task to evaluate the effect of these chemical substances on the environment before and druing construction but also in the hardened state

In this article we focus on the toxicological and physico chemical properties of the mostely used products in Europe (water reducers and high range water reducers) and their leaching behaviour in recycled concrete.

Keywords: concrete admixtures, environment, leaching, superplasticizers, concrete demolition material

1. Introduction

Concrete admixtures are used specifically to improve workability and the end quality of the concrete to be obtained. With regulation use of concrete admixtures the pollution of the environment to be expected is very slight so that the products can be rated as environmentally compatible.

2. What are concrete admixtures and why are they needed?

Modern concrete contains in addition to cement, gravel, sand, additive and air normally also one or more concrete admixtures. In this way, depending on the nature of the admixture, it is possible to influence specifically concrete properties such as strength, flow behaviour, resistance to frost and deicing salts, sulphate resistance, setting characteristics, pumpability and others. According to prEN 934-2 (Final Draft 1994) a distinction is made between the following categories of concrete admixture (Table 1): The action of superplasticizers is based on long familiar principles. Abram found at the beginning of this century that for a given set of materials and conditions the compressive strength of concrete depends on the proportion of cement in the cement paste. However, as the cement paste consists of cement and water, it becomes clear that the so-called water/cement (w/c) ratio is to be kept low in order to achieve good strength values and durability, for as is well known only a part (approx. 25%) of the water can react with the cement, the excess water evaporating leaving behind pores. The w/c ratio thus has a dominating influence on the properties of the green and the hardened concrete. Using plasticizers or rather superplasticizers (SP) makes it easy to achieve this objective. Air-entraining agents, for example, are indispensible for making concrete resistant to frost and deicing salts. Air voids of a certain size and distribution are deliberately created to act as expansion spaces capable of absorbing the pressure of the freezing water.

	German abbreviation
Concrete plasticizers	(BV)
Superplasticizers (SP)	(HBV)

Antifreeze agents	(FS)

Table 1: Classification of concrete admixtures

Ecological demands on concrete and also the continuous adaptation and development of construction and working techniques represent a constant challenge to researchers and developers of concrete admixtures. An "ecological concrete" is a concrete which according to ecological criteria has an optimized composition of the individual components (sand/gravel, cement, water, concrete admixture, additives), A crucial criterion in this is the durability of the concrete exposed to the environment. The latter is positively influenced by the proper use of modern concrete admixtures. In total according to FSHBZ statistics approx 14,000 t of concrete admixtures were sold in Switzerland in 1994, whereby the SPs with approx. 75% make up the largest part. Today approximately one third of concrete placed has been modified with a concrete admixture.

Environmental pollution from the use of concrete admixtures has been critically questioned by various quarters. This publication summarizes the state of knowledge regarding environmental pollution caused by the use of concrete admixtures and the effects on man and environment to be expected.

3. Choice of concrete admixtures used for the study

From the different concrete admixtures described above it was superplasticizers (melamine sulphonate polymers and naphthalene sulphonate polymers) that were chosen because of their wide range of uses., the total quantity used in construction and the material properties.

4. Are concrete admixtures environmental1 incompatible?

The effects of chemical products on man and the environment are assessed in accordance with the relevant chemicals legislation [1, 2, 3]. All emissions to be expected in the course of the life cycle of a product are covered and assessed with regard to possible effects.

The following procedure has proved itself in practice:
I. Data collection and evaluation
II, Listing of the life cycle
III. Assessment of environmental compatibility
IV. Measures for improving environmental compatibility

I. Data collection and evaluation
Data from safety data sheets, product tests and scientific studies were used as the database, Various data are product-specific so that special test methods were used. In part the investigations were conducted in cooperation with relevant institutes (e.g. EAWAG[1], EMPA[2]). A selection of relevant data for the currently most important superplasticizers is summarized in Table 2.

[1] Swiss Federal Institute for water, Waste water and Water Protection (EAWAG Diibendorf, Switzerland)
[2] Swiss Federal Materials Testing Institute (EMPA Diibendorf, Switzerland)

Parameter	Naphthalene sulphonate polymer (NSP)	Melamine sulphonate polymer (MSP)
Water solubility	>100 g/l	>100 g/l
Octanaüwater distribution Cow (log)	<<-1*	6-4
Toxicity for mammals LD50 rodent (mg/kg)	3400->4000	>4000
Aquatic toxicity EC50 fish (mgA)	100-2000	560-3200
Aquatic toxicity EC50 daphnia (mgA)	>220	>100

Biodegradability OECD 302B (%)	43	15-51
Poison category (CH)	free	free
Water hazard class (D)	~ 1	1

* = calculated

Table 2: Selection of relevant data for superplasticizers

All substances are readily soluble in water, have very low octanol/water distribution coefficients (i.e. they do not concentrate in the fatty tissue of organisms) and are not volatile. They are classified in Switzerland as non-toxic and have an acute toxic effect on water organisms only at very high concentrations. They are not easily biodegradable.

II. Listing of the life cycle

The following stages in the life cycle of concrete admixtures can lead to pollution of the environment:

- Production
- Transport
- Storage/handling
- Use of the concrete admixtures
- Service life of the building
- Recycling of concrete from demolition
- Disposal of building waste and residues.

Figure 1 shows the simplified life cycle of concrete admixtures taking the example of the use of ready-mixed concrete.

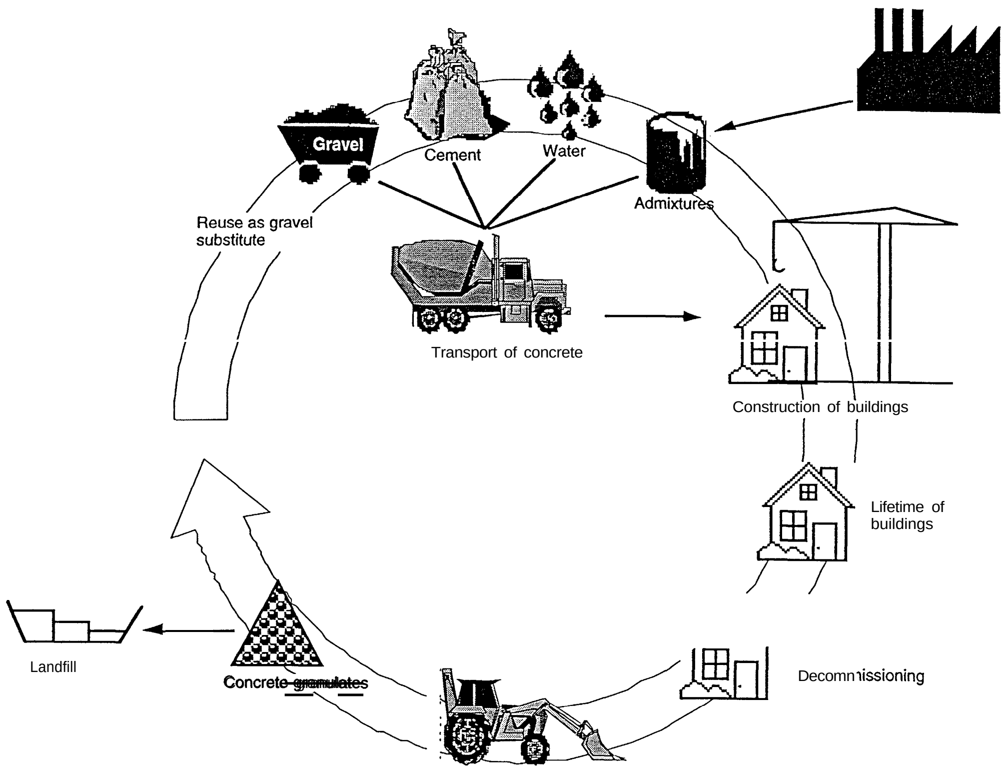

Fig. 1: Simplified life-cycle of concrete admixture

III. Assessment of environmental compatibility

The burden on man and environment was assessed using the emissions found or estimated for each stage of the life cycle. The toxicological and ecotoxicological characteristics of the concrete admixtures served as a basis for the assessment.

4.1 Emission and mass flows

Pollution from SPs was determined experimentally or estimated for each stage of the life cycle of the products It was found that environmental pollution can occur above all when using SPs and when storing concrete granulate containing SPs and when using this granulate in road construction.

4.1.1 Production

Thanks to specific treatment of waste water with recovery of the substances contained in the waste water only very small quantities of SPs get into public purification plants.

4.1.2 Use

It can be assumed that when using SPs in producing precast concrete units no relevant emissions occur.

The use of SPs for preparing in-situ concrete is in swift decline. With proper handling the environmental pollution (e.g. washing of implements) is expected to be very slight.

When used for ready-mixed concrete the main focus is on waste disposal from the rinsing of ready-mix trucks. These emissions are strongly on the decline as on the one hand rinsing water is being increasingly used for preparing concrete and on the other retarders can be added to the concrete remaining in the trucks which delay hardening.

4.1.3 Emissions from existing prefab units

EMPA studies on concrete test specimens have shown that SPs do not cause any appreciable emissions of volatile organic compounds [5].

4.1.4 Emissions from concrete demolition material

Leaching tests with broken material (4-8 mm) from defined concrete test specimens have shown that it is not the originally used SPs that are leached but their decomposition products.

These are readily biodegradable which is favourable for environmental behaviour. Under the strict conditions of testing a total of some 20-30% of the SPs used were leached. As estimates taking one product showed, more than half of the leached material is present in the form of decomposition products.

A comparison of the leachability of defined test specimens containing SPs with concrete granulate from recyclers has shown that only part of the leachable substances come from the use of SPs (Fig. 2). A large part must come from products used in construction (coatings, adhesives, mastic joint sealers, etc.), from foreign materials (wood, gypsum, asphalt, etc.) and the cement itself.

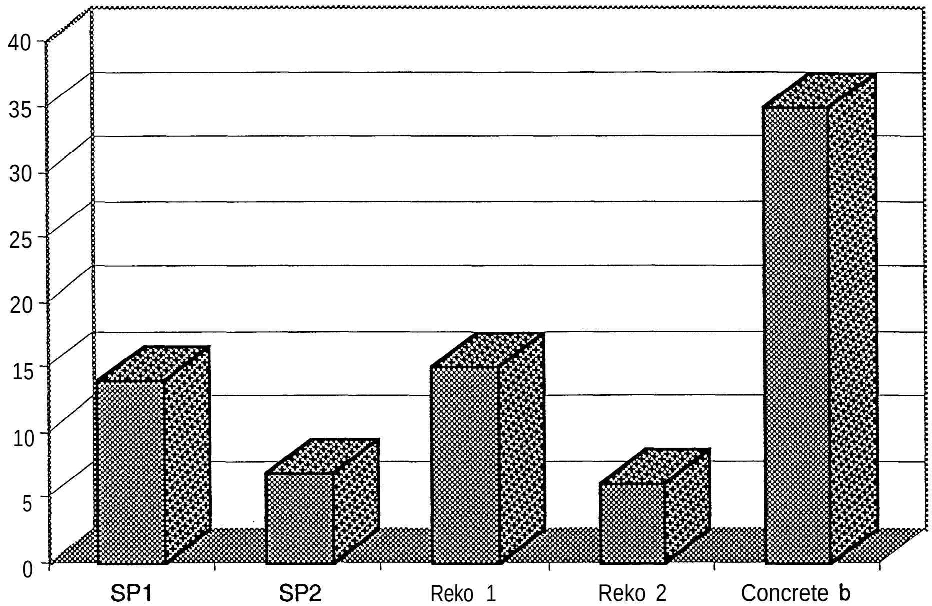

Fig. 2 - List of contents in dissolved organic carbon (DOC) in eluates from concrete specimens (broken material). Specimens which contain only SPs (SP 1 = naphthalene sulphonate polymer, SP 2 = melamine sulphonate polymer) are compared with concrete granulate specimens (Reko 1 and 2) and coated concrete demolition material. SP specimens contain 4% active substance in relation to the cement weight.

Concrete demolition material is stored in heaps in the open until it is reused (Fig. 3). As concrete admixtures have only found widespread use in about the last 30 years, it can be assumed that the concrete demolition material currently becoming available should in large part be free of concrete admixtures. In order to be able to estimate future emissions from the leaching of SPs, tests were carried out with test specimens with a defined SP content. If the total quantity of concrete demolition material (SPs at today's batching rate) becoming available yearly in the Canton of Zurich is stored in the open, max. 300 kg of SPs in total can be leached each year by precipitation falling upon it. Similar considerations with the use of concrete granulate in unbound form for road beds (Fig. 2) show emissions of max. 900 kg of SPs a year for the whole Canton of Zurich, These emissions would in the worst case (assumption: there is no degradation) lead to measurable concentrations of organic compounds of max. 0.2 mg DOCA in the ground water immediately below the heaps and roads in question.

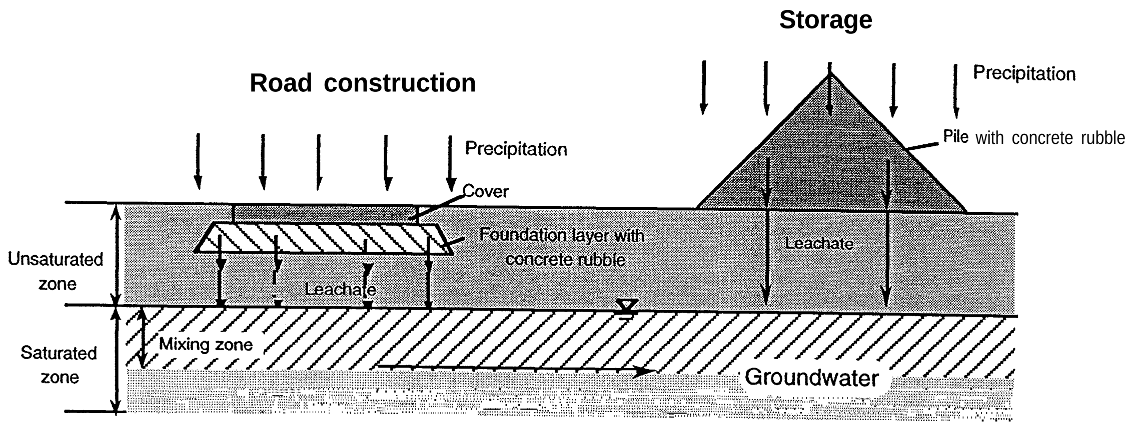

Fig. 3 - Typical scenarios with occurrence of precipitation when storing concrete demolition material or granulate (right) and when using processed concrete demolition material as road bed (left).

These estimates are based on very unfavourable assumptions. If one considers, for example, the guidelines issued by the Canton of Zurich for the use of secondary building materials [6] the emissions to be expected should be less by l-2 orders of magnitude.

Swiss legislation on waste [TVA, 7] stipulates that building waste must be recycled if possible. Concrete granulate is mostly used in hydraulically bound form as a substitute for gravel. The question therefore arises of whether an accumulation occurs with the repeated recycling of concrete with the addition of concrete admixtures. Calculations show that at most a doubled content results with a proportion of 70% concrete granulate in the aggregate (assumption: infinitely many recyclings).

No problems arising from SPs are to be expected when dumping concrete demolition material as an inert substance in compliance with legislation (TVA).

4.2 Risk assessment summary

On the basis of existing data and estimates the superplasticizers under consideration can hardly be classified as ecologically hazardous from the point of view of environmental technology, With correct use and disposal of SPs no adverse effects are to be expected for the health of man and environment. As the concrete admixtures are very readily soluble in water, no accumulation is to be expected in soils, water-bearing strata or organisms, The products used as SPs are also used in significantly greater quantities in other sectors, Caution is therefore required in the interpretation of measurement data, for example when it comes to waste water.

IV. Measures for improving environmental compatibility

Emissions which lead to significant burdening of the environment must be reduced to a compatible level. In principle a distinction is made between three categories of measure:

- Information and recommendations (e.g. recommendations on on-the-job safety)
- Safety measures (e.g. taking-back of product residues)
- Reduction (e.g. restrictions on use)

In general measures to improve the environmental compatibility of these products should be taken where the greatest emissions are to be expected, In the case of ready-mixed concrete wash water is increasingly being reused as gauging water and unused concrete is being mixed and used again with fresh concrete.

Of the sources of emission discussed here leaching during storage should have the greatest potential effects on the environment. In the context of precautionary measures therefore care should be taken that yards where concrete demolition material is stored are drained and the drained water led off to a purification plant.

The incorporation of concrete demolition material in road foundations should be far less relevant. In order here too to minimize emissions into ground water, the concrete demolition material should as far as possible be used in bound form. This reduces the amount of water infiltrating and thus emissions into the subgrade,

5. A look into the future

Even if the database for concrete admixtures can be described as good compared with other products the knowledge gaps still found during this study have been partially completed. The following questions are dealt with in particular:

How quickly do concrete admixtures decompose in concrete?
How is the leaching behaviour of concrete admixtures from intact concrete structures?

In another step environmental compatibility is to be balanced against the benefit of concrete admixtures, which will allow an overall assessment of concrete admixtures. New products are in future to be assessed in accordance with the above-mentioned procedure and taking into account the experience gained.

Indoor Environment and sustainable development
Toward a more ascetic way of living

G. Blachère, AUXIRBat, France

Abstract :

The problem of a building compatible with sustainable development involves the adequation of four factors :

The increase of the world human population
The increasing level of comfort
The consumption of resources to achieve this level
The disponibility of these resources on Earth

Until today almost all the efforts to solve the problem have been concentrated on the third factor.

It is rational to examine the possiblity to act on the others.

Here it is proposed to examine the possibility to lessen the level of comfort in buildings. Indoor temperature has been legally lowered in the 70s.

People lived in less comfortable situations in the past centuries. Is it a step-back today feasable?

A. Generals

A.1. Man is a factor of concern to the future of this planet. Are we conscious really that he rivals with large volcanos in the matter of atmospheric pollution and has no rival at all for water pollution and natural products' consumption ?

His action is growing worst for two facts :

- its multiplication,
- the increase in the level of his comfort and commodities requirements.

The consequences of these two facts are :

- increase in pollution of all kinds, arithmatically speaking - two billion people pollute twice as much as one billion,
- increase in consumption of building materials largerly based on natural resources,
- increase in the energy used to exploit buildings.

A.2. The multiplication of men is frequently evocated - and its amplitude discussed.

An optimistic view is that this expansion will stop in some decennies after the doubling of the population. In reality nobody knows, and some prudent (and exposed) countries have taken measures, with more or less luck.

This point will not be dealt with further here.

But the other point : the increase in building comfort and commodities has practically never been dealt with.

Nevertheless, it is a really important point :

From a rough approach we can conclude that : of the actual population a tenth only enjoy the level of comfort and commodities we know in the middle class of the affluent countries, half of the rest consumes half of this level, and the rest a fifth.

Thus if the world population doubles and if it should reach the level of standard of living of the affluent countries, the consumption will be multiplied by five.

A.3 This rise in consumption concerns energy as well as building products. The last mobilises enormous quantities of products and wastes - in construction, exploitation and demolition.

A consequence of all that is that, if reasonable, we should think over the problem under this form : What standard of comfort and commodities' level is compatible, on Earth, with the sustainable development ?

And if you write levels in place of level, imagine the problems.

B. The standard of life level of the human beings in their habitation - Its evolution

B.1 In the affluent countries, the housing energy consumption consists in :

- Heating in cold seansons, air conditionning in hot seasons
- Using sanitary hot water
- Cooking
- Lighting without restrictions nor savings
- Using home and offices equipments.

The sum gives energy expenses of about a yearly 2 Tep (Equivalent oil ton) per home.

As for the volume of constructions, the UN-ECE Compendium of Model Provisions for Building Codes set a minimum area of 12 to 14 m2 of living space per inhabitant.

And the volume of housing construction in a country is roughly equal to that of constructions of other types.

The move towards more comfort is natural.

Thus in France since the beginning of the century, the duration of the heating period passed from 4 months to 5 in 1950 to 8 months today.

One room and the kitchen were heated. Today we enjoy central heating.

And the "clim" (air conditionning) is invading every type of buildings.

The home and office equipments rised from zero to all we enjoy today.

Etc. etc.

And people certainly appreciate all this progress.

But it is continuing :

A demand for more heat comfort doesn't really exist, but new building equipments are appearing which, in general, people accept and which power distributors and manufacturers push for. And, as a common law, no brake exists.

On another hand, less rich people in less rich countries ambitionnate to reach the level of comfort standards of the affluents.

A question is clearly evident :

Are the moves toward more comfort in the rich countries,

and the move of the less rich or poors toward the level of the rich,

are these moves compatible with the sustainable development ?

To answer this question requires :

- Forecastings about volume of populations and level of consumptions linked to the living comfort (but it is always difficult to forecast, especially the future...)

Estimating the level of future energy resources, the mass of natural resources man can exploite without endangering the sustainable development.

But is the concern justified ?

The optimists will say : "The increase in population will stop spontaneously, man will develop new energy sources, non polluting and unlimited, like nuclear fusion or cover the deserts with solar collectors. And all is good - Maybe, maybe not.

It is not reasonable to, at least, study what could be done to face the difficulties, if and when necessary.

In short, to study how and how far, by the means to reduce consumptions to catch a given level of comfort, it is possible to lessen the level of comfort, itself. Id est to live in a more ascetic way than today in affluent countries.

C. Thinking over the problems

Three ways of lowering the standard of living exist :

Coercision

Conviction

Cost correlations, which in fact back stop the two first.

Advanced countries have lived since the 1970s an episode of such lowering :

These countries have been confronted with the necessity, for national economic reasons, to lower their oil consumption. They imposed to lower the winter heating reference operative temperature of 20°C to 19°C. The economy was remarquable : in France about 0,2 Tep per home.

The measure was accepted (which does not mean respected) because people faced a private economic problem. So they accepted to wear a sweater at home, to cut down the heating bill.

But other measures could not be as easily accepted :

The necessary restrictions of air conditionning will face the opposition of the building occupants, of the air conditionning industry, and of the power distributors.

To overcome the obstacle it seems to be necessary to sensitize the people to the problems of sustainable development, to use a lot of coercition, probably under the form of taxations. That people and governments take unpleasant measures for the sake of solving problems of coming generations lies in the field of Vitruve...

What could be envisaged is a study to find the possible restrictions in comfort :

- room temperatures, warm water consumption, dimensions of the rooms, etc. and to disseminate a guide for people concerned with sustainable development.

- to examine the best way - under the form of regulatory obligations, or tax actions, to enforce the corresponding measures.

Classification of Finishing Materials '95

Kari Vikström, The Building Information Institute, Helsinki, Finland

Abstract

The purpose of the Classification of Finishing Materials '95 is to set emission requirements for the materials used in common living and work spaces to achieve good indoor air quality. The goal is to enhance the use and development of low-emitting materials.

The Classification of Finishing Materials has three categories, category M1 being the best and category M3 containing materials with highest emission rates and materials that are not tested. Because total emission and concentration in room air depend on the amount of used materials, the Classification gives guidelines for the use of various materials.

Category M1 is designated for natural materials, such as stone and glass, which we know to be safe in respect of emission and for materials that fulfil the following requirements:

- emission of TVOC is below 0.2 mg/m2h
- emission of formaldehyde is below 0.05 mg/m2h
- emission of ammonia is below 0.03 mg/m2h
- emission of carcinogenic compounds (due to IARC) is below 0.005 mg/m2h
- material is not odorous

Until December 1997 The Building Information Institute has classified 127 finishing materials. Several houses are being built, in which finishing materials have been selected according to the Classification of Finishing Materials.

Keywords: Indoor air, finishing materials, classification, emissions, odours

Introduction

In its meeting of 4 October 1995, the Board of Directors of The Building Information Institute, BII, established Committee TK 185 to study indoor air quality, construction works, and finishing material classifications. Committee TK 185 is responsible for maintaining and developing classifications for indoor air quality, construction works, and finishing materials based on procedures established in the Indoor Air Association Classification Bulletin No. 95. It is the committee's continuous responsibility, aside from determining to which class a material belongs based on the specifications provided, to reach decisions relating to detailed classification procedures such as testing frequency and the formulation of laboratory testing requirements. Additionally, the Committee monitors the use of classification symbols in marketing and takes legal action to correct any possible abuses.

These instructions, approved by BII committee TK 185 in its meeting of 27 February 1996, describe the principles underlying emissions classification procedures.

Proof of Classification of Finishing Materials

Emission classifications are defined in Classification of Finishing Materials Bulletin - ML 95 (15 June 1995). Classification requires an approved testing report conducted according to required procedures.

Requirements for Finishing Materials

Category M1 is designated for emission tested materials whose emissions fulfill the following requirements:

- emission of TVOC is below 0.2 mg/m^2h;
- emission of formaldehyde (H_2CO) is below 0.05 mg/m^2h;
- emission of ammonia (NH_3) is below 0.03 mg/m^2h;
- emission of carcinogenic compounds according to category 1 IARC classification is below 0.005 mg/m^2h;
- the material is not odorous (dissatisfaction with the odor is below 15%)

Category M1 includes also natural materials which are known to be safe in respect of emissions:

- brick
- natural stone and marble
- ceramic tile
- glass
- metal surfaces
- board and log (Finnish wood) whose emissions as fresh, however, may be higher than those specified for materials of category M1.

Category M2 is designated for emission tested materials whose emissions fulfill the following requirements:

- emission of TVOC is below 0.4 mg/m^2h;
- emission of formaldehyde (H_2CO) is below 0.125 mg/m^2h;
- emission of ammonia (NH_3) is below 0.06 mg/m^2h;
- emission of carcinogenic compounds according to category 1 IARC classification is below 0.005 mg/m^2h;
- the material is not strongly odorous (dissatisfaction with the odor is below 30%)

Category M3 includes materials which do not have emission data or the emissions exceed the values specified for materials in category M2.

Application

Classifications' of finishing materials are granted by BII. The application and its supporting documentation is to contain the product's function, trade names and the

Testing Procedure

Sample selection, analysis, and material emissions measurements shall be undertaken according to procedures specified in *European Data Base on Indoor Air Pollution Sources in Buildings. Protocol for testing of building materials.* Odour-related emission measurements shall be conducted according to *Odour Emission Measurement Instructions for Surface Materials.*

If Flec chambers are used in chemical testing, a control sample shall be simultaneously measured for ageing and odour-related evaluation in applicable chambers.

Products are tested for the following properties:

- total volatile organic compounds TVOC,
- formaldehyde H_2CO,
- ammonia NH,
- carcinogens and
- odours.

Selection of testing laboratory

Sample selection, analysis, and material emissions measurements shall be undertaken according to product group acceptance principles by an impartial and competent laboratory with quality assurance adhering to such standards as SFS-EN IS0 9003. Accredited laboratories may be recommended for use.

Product marking

When classification has been granted, products, packaging, product specifications, and instructions for use are marked with classification symbols Ml, M2, or M3.

Additionally, product specifications shall specify any possible limitations for product use or application conditions that would serve to increase emission levels such as:

- application conditions, applicability.
- base requirements (moisture, temperature).
- preliminary treatment.
- operational safety.
- packaging.
- transportation (packaging).
- storage (storage conditions, i.e. packaged, wrapped in plastic).
- use and installation instructions.
- cleaning directions (detergent pH requirements).
- environmental protection and waste treatment.

Product marketing

Classification symbols may be used in advertising and marketing for specific products. Classification symbols may not be used in marketing to create the impression that an entire company or all of its products are classified.

Filing Appeals

Companies wishing to appeal decisions rendered by BII concerning user rights or their rejection may file an appeal in written form within **14** days from the date the decision was received to BII's representative, who will forward it to Committee TK 185 for adjudication.

Directory

BII maintains and publishes a directory of currently valid classified products and holders of user rights.

Reported health problems and indoor environment in single-family houses

H. Högberg
Centre for Built Environment, Royal Institute of Technology, Gävle, Sweden

Abstract
The objective is to investigate the relationship between self-reported health problems and complaints of the indoor climate, and building characteristics and physical indoor climate in single-family houses.

Data collected from 781 single-family houses are used. These data consist of building characteristics collected from on site inspections, indoor climate measurements (temperature, ventilation, humidity of indoor air) and the residents' perceptions of their indoor climate and health obtained from postal questionnaires. A group of 77 single-family houses, in which the residents reported complaints and symptoms at enhanced rates is compared to 704 randomly selected single-family houses.

The principal finding is a significant association between complaints and symptoms and water/mould/rot damage. Complaints and symptoms are also more frequent in houses grounded on concrete slab and in homes with wall-to-wall carpets. Hence, this study support evidence that moisture may cause health problems in single-family houses. This study also indicates that reported allergic disorders, complaints and symptoms are positively correlated. Controlling for allergic disorders, the results remain. We do not find any correlation between perceived and measured indoor climate, however.
Key words: building characteristics, complaints, health problems, indoor climate, moisture, single-family houses.

1 Introduction

In Sweden as well as in most of the developed countries a dramatic improvement of the housing conditions have taken place. Nevertheless, health problems are still experienced in office buildings, schools and residential buildings. Sick Building Syndrome (SBS) has become a common term in indoor environment research. SBS includes a combination of general symptoms and symptoms of mucosal membranes and skin. Moreover, it is implied that the symptoms are related to residence or work in a certain building.

The phenomena of SBS and building-related illness/symptoms have been subject to intense research during the last decades. Still, no specific factor or agent causing SBS or building-related illness has been proven. However, certain environments have been suspected to increase the risk for SBS or health problems, especially damp buildings [1,2,3,4,5,6]. Several studies report associations between type of ventilation system, especially modern systems with humidifiers, and symptoms in office buildings [7,8,9,10]. The results are inconclusive, however, and reports of association between air flow rates and health are scarce [11,121.

Only a few statistically representative cross-sectional studies of national scope have been carried out in order to estimate the extent of SBS and building-related health problems. One of them, the ELIB-study [13], indicated that 600,000 to 900,000 Swedish residents, or about 10% of the population, were exposed to indoor climate in their residences that may affect their health and well-being.

The ELIB-study concluded that complaints about the indoor climate and symptoms were more frequent in multi-family houses compared to single-family houses. However, the physical indoor climate was less favourable in single-family houses compared to dwellings in multi-family houses. In spite of lower frequencies, there are obviously residents in single-family houses who are dissatisfied with their indoor environment and also experience some health problems. Are their houses or the households different in any way?

The specific questions to be discussed in this paper are:

- Are single-family houses in which many residents complain about the indoor climate or report health problems technically different than other houses?
- Are the indoor environment different?
- Is dampness a common factor in those houses?

2 Method

The data used in this study were collected in the ELIB-study [13]. They consist of physical measurements of indoor climate, technical data of building characteristics and data of perceived indoor climate and symptoms.

Measurements of the indoor climate were all of passive integrating type. Monthly averages of temperature, relative humidity and ventilation rate during the heating season were calculated.

Technical inspections on site were performed by technical consultants using a special inspection form. The data included type, age and condition of the building, structural and thermal insulation characteristics, ventilation system, heating system, indicators of moisture problems, and housing characteristics.

The postal questionnaire was developed at the Department of Occupational and Environmental Medicine at the Örebro Medical Centre Hospital [14]. The questionnaire asked the residents about the perception of 11 indoor climate factors and 12 symptoms, see Table 1. The recall period was three months. Three alternative answers were given: "Yes, often (every week)", "Yes, sometimes" and "No, never". The answer "Yes, often" is interpreted as that the trouble or symptom exist.

The total number of single-family houses in the study is 78 1. Based on the results of the questionnaire 77 single-family houses were identified in which at least one of the occupants reported three complaints or more of indoor climate or at least two symptoms. Of the remaining 704 single-family houses in which the residents not had enhanced rates of problems with indoor environment or health problems there were 233 houses in which the occupants had no complaints or symptoms at all. Thus, the three study groups are: "problem houses"(77), "reference houses"(704), and "problem-free houses"(233), see Table 1.

As the criteria for categorising the houses is determined by the residents response to questions about perception of indoor climate and symptoms, important personal related variables in the analysis are made on summary measures of individuals in the households.

In the univariate statistical analysis we cross-tabulate the three groups of houses against the variable of interest in nominal, ordinal or interval scale. Some significant risk and control variables identified in the univariate analysis are then included in two multiple logistic regression models. The independent variables are the same in both models but the outcome in the first logistic model is the binary variable of problem house (value=l) vs. reference house (value=O) and in the second model problem house (value=l) vs. problem-free house (value=O).

3 Results

The proportion of women living in the problem houses is 50%. In the reference houses and in the problem-free houses the proportion of women is 48%. There is a significantly greater proportion of younger people (<40 years of age) in the problem houses compared to the other types of houses. Also, there is a significantly greater proportion of residents suffering from allergic disorders in problem houses compared to the other types of houses. Table 1 shows the proportion of residents answering "Yes, often" to the questions about indoor climate complaints, "Yes" to the questions about allergic disorders, and "Yes, often" to questions about symptoms. The criteria for categorising the houses is reflected in the substantial differences in frequencies of complaints and symptoms.

Variable	Individuals (%) in		
	Problem houses	Reference houses	Problem-free houses
Draughts	6.8	2.0	1.3
Too high room temperature	1.5	1.9	0.8
Varying room temperature	9.8	2.8	1.3
Too low room temperature	6.8	1.5	0.3
Stuffy air	6.7	2.2	0.0
Dry air	15.8	4.0	1.5
Unpleasant smells	5.2	1.5	0.0
Static electricity	1.5	0.4	0.3
Passive smoking	7.5	1.9	0.5
Noise	3.7	0.6	0.3
Dust and dirt	9.8	2.0	0.3
Asthmatic problems	19.1	6.3	5.5
Hay fever	21.2	12.6	9.1
Eczema	20.5	14.2	11.1
Fatigue	26.2	8.2	4.7
Feeling heavyheaded	11.6	2.9	1.1
Headache	11.7	3.4	0.8
Nausea, dizziness	6.1	0.6	0.0
Concentration difficulties	3.1	0.6	0.0
Eye problems	6.8	1.8	0.8

Coughs	7.0	1.7	0.3
Facial skin problems	12.3	2.6	1.0
Itchy scalp	8.5	4.2	0.8
Skin problems on hands	10.0	2.6	2.4
Number of houses in the sample	77	704	233

Table 1. Proportion of individuals reporting complaints of their indoor climate and suffering from allergic disorders and symptoms.

Many of the building and housing characteristics are similar in the studied houses, see table 2. However, some differences may be noted. Moisture damage is more common in problem houses. It also seems as the problem houses are more crowded and built on slab on the ground to a greater extent. Urban localisation of the houses as well as rented ownership are more common among problem houses.

As can be seen from table 3 there are no major differences in mean values and medians of climate measurements between reference houses and problem houses. However, the mean value of ventilation rates, expressed as l/s,person, is somewhat lower among problem houses compared to reference houses and problem-free houses (not significant though). Single-family houses with problems appear to be slightly newer than the reference houses (p-value=0.06).

Variable	Value	Single-family houses % Problem	Reference	Problem-free
Type of building	Detached houses	74.0	80.0	82.4

Indoor relative humidity	39.5	38.9	40.0	38.5	38.0	39.0
Construction year	1961	1954	1959	1971	1965	1966

Table 3. Physical indoor climate measurements in reference, problem, and problem-free houses (P-f).

In the multiple analysis we find the following risk variables significantly associated with occurrence of high rates of complaints and health problems: At least one moisture/mould/rot damage in the house, number of allergic disorders in the household and living space. In addition, foundation by slab on the ground and wall-to-wall carpets are significant in the model comparing problem houses to problem-free houses. Variables included in the model as control variables and confounding variables are: Year of construction (-1940, 1941-60, 1961-75, 1976-), area of localisation (rural, urban), type of ventilation system (natural, exhaust, supply and exhaust), average age of residents in the home and indoor temperature.

Factors	**Odds Ratios (CI)**	
	Reference	Problem-free houses
Foundation by slab on the ground	1.80 (0.89-3.65)	2.40 (1 .OO-5.75)

4 Discussion

In the multiple logistic regression analysis the associations between occurrence of at least one moisture damage and enhanced rates of complaints or health problems are significant, with odds ratios of 2.09 (1.14-3.85) and 3.60 (1.66-7.83), respectively. The physical indoor climate is, however, not significantly associated with enhanced frequencies of complaints or health problems, but indoor temperature, relative humidity and ventilation rate might act as confounders and/or effect modifiers. In Sweden high relative humidity indoors during winter time is unusual. The mean RH in single-family houses is just below 40%, and the values range from 21% to 80%, with just a few values above 60%. Associations between relative humidity and respiratory symptoms has been found in but a few of the studies made, more often these association are not proven [4]. In spite of dry air, problems from moisture still may occur due to air tightness and long time spent indoor during winter time [5]. Thus, it is not surprising to find that relative humidity is not significantly correlated with enhanced rates of complaints and symptoms. Different distributions of constructing year, area of localisation, ventilation system and age of the residents are controlled for by including these variables in the two models.

According to table 1, the frequencies of allergic disorders are much higher among residents in problem houses. Furthermore, the frequencies of allergic disorders are lowest among residents in problem-free houses. It might be so that many of those who report symptoms have got their symptoms from allergic disorders. Thus, occurrence of allergies must be controlled for in a model to describe the relationship between indoor climate and symptoms. The odds ratio for number of allergic disorders in the household is significant and slightly higher in comparison with problem-free houses.

With this type of cross-sectional sample survey we may have problem with selection bias. People with many symptoms and/or people with a tendency of complaining may have a tendency to live in houses with certain characteristics. Factors that may influence the way of how to choose, or be forced into standards of living are, e.g. age, family status, disposable income, employment, chronically diseases and allergic disorders. By controlling for these types of variables one may overcome some of the problems with selection bias. In this study we are only able to consider age and allergic disorders. In a forthcoming study we are going to consider other socio-economic variables as controls.

Some alternative multiple logistic regression models has been tested to assess the importance of certain variables and the stability of estimated coefficients of the main variables. The significant variables allergic disorders, space and moisture damage remains stable, but if ventilation rate is deleted from the model the estimated coefficients change somewhat. Comparing the model log-likelihood for the alternative models concludes a significant impact of ventilation rate on parameter estimates.

For testing if the estimated model is sensitive to the included observations, two independent samples from the available data set has been drawn. The sample sizes are 90% in both cases. The estimated coefficients does not change dramatically, and the conclusions from those models are the same.

The most important result from this study is that moisture damage based on inspection is an important factor for high rates of complaint and health problems. Comparing problem houses to problem-free houses strengthen this tendency. Households with many complaints and health problems are more frequently found in houses built on concrete slab and in apartments with wall-to-wall carpeting.

The approach to define houses as problematic or “sick” on summary measures of symptoms and complaints has limited value for assessment of the aetiology of building related health problems [15]. Various symptoms and complaint patterns has probably its own risk factors. In the ELIB-study we collected many variables related to dampness in the buildings which are to be analysed with respect to certain groups of symptoms and individual symptoms. Moreover, selection bias, living conditions and different socio-economic factors should be studied more thoroughly. This will be done in further analysis of this data, along with a systematic assessment of interaction.

Abstract

The windows are important parts of the building shield due to the indoor climate and to the heat losses from the building. Modern windows are designed with two or three panes in order to improve their thermal performance. The cavities between the panes are often hermetically sealed and filled with a gas with low thermal conductivity. A numerical study has been undertaken of the natural convection within the cavity, which plays an important role in the thermal performance of the window. Thermal radiation transfer will certainly play a major role in the heat transfer process; however, the focus here will be on the convective heat transfer.

The numerical calculations are performed on a model with two vertical parallel panes with constant surface temperatures. The cavity between the vertical panes is enclosed with insulated plates at the top and at the bottom of the model. The model is two-dimensional and the flow is assumed to be steady, laminar and incompressible. The governing equations for conservation of mass, momentum and energy are solved by the finite element code FIDAP.

The numerical results in the present study have been validated with the measurement results presented earlier by Elsherbiny [1]. Flow patterns, velocity and temperature profiles within the cavity are presented. The variation of the Nusselt number along the height of the hot pane as a function of the Rayleigh number is also investigated.

Correlation for the average Nusselt number, Nu, as a function of aspect ratio, *A*, and the Rayleigh number, *Ra*, are determined. The correlation covers the range of values for, *A*, and, *Ra*, which are of practical interest in window construction. Based on regression analysis, the following correlation is proposed, $Nu = 1+ 0.00137\, A^{-1.137}\, Ra$. In addition, for further validating of the present study, the predicted results are compared with the results obtained theoretically and numerically by others.

Introduction

In Sweden and the other Nordic countries the climate is cold several months a year. To a great part the indoor climate of a building depends on the outdoor temperature and the quality of the insulation affects heat transfer in the building, i.e. the components of the building shield. The windows are an important building component for the indoor climate, but there is a down-draught problem, as the temperature is lower on the glass than the indoor air. For the last 50 years, the construction of the windows has developed from single-glazed constructions to today's triple-glazed constructions, with enclosed spaces between the panes, see Moshfegh et al [2]. Examples of gases, usually used in these enclosed spaces, are air, argon, krypton, xenon, CO_2 and SF_6.

Natural convection in vertical and inclined spaces has been investigated both analytically and experimentally for the last 40 years. The first important theoretical analysis was done by Batchelor [3] in 1954, after that many more studies have been carried out. Over the years, the studies have focused different circumstances such as limited Rayleigh numbers, *Ra*, and aspect ratios, *A*. In 1980 Elsherbiny [1] investigated a large scale of Rayleigh numbers and aspect ratios. As computer capacity has improved during the last decade, the possibility to solve the problems numerically has increased considerably. In 1995 H. Schweiger et al [4] made numerical simulations on laminar natural convection in rectangular cavities for different Rayleigh numbers at $A = 40$.

The purpose of this paper is to analyse numerically the convection between two vertical parallel plates forming an enclosed cavity. The region, which is of interest in this paper, is window constructions with Rayleigh numbers up to 20000 and the aspect ratio from 40 to 130. This region normally covers window constructions with a space width of 10- 15 mm, a height from 400 to 1900 mm and with common gases inside the cavity such as air and argon, with outside temperatures normal for Nordic countries in the wintertime.

The numerical calculations will solve the governing equations for conservation of mass, momentum and energy. The actual model is two-dimensional and the flow is steady, laminar and incompressible. The physical model, which the governing equations will be solved on, is a rectangular cavity with an isolated top and bottom and with two vertical plates of different temperatures. The governing equations are solved by the finite element method. The results from the numerical calculations are validated with results from other investigators. The intention with these numerical calculations is to find a correlation where the Nusselt number depends on both the Rayleigh number and the aspect ratio.

Physical model

The numerical calculation is made on a model, very close to reality (see figure 1). *H* is the height of the model, constantly 640 mm. *L* varying from 4.9 mm to 32 mm and is the width of the enclosed cavity between the two vertical panes. Heat transfer between two panes of different surface temperatures in an enclosed space can be performed with the three mechanisms conduction, convection and radiation. Convection and conduction are the two mechanisms considered in this paper. The radiative heat transfer is not negligible but it is not taken into account in the present study. The physical model is intended to be an enclosed space in a window construction therefore the Rayleigh number, *Ra,* and the aspect ratio, *A*, are limited to values which are of interest for window application. Air, argon, krypton, xenon, SF_6 and CO_2 are conceivable gases to use within the cavity in window constructions. The Rayleigh number and aspect ratio of interest is up to 20000 respectively 40-130.

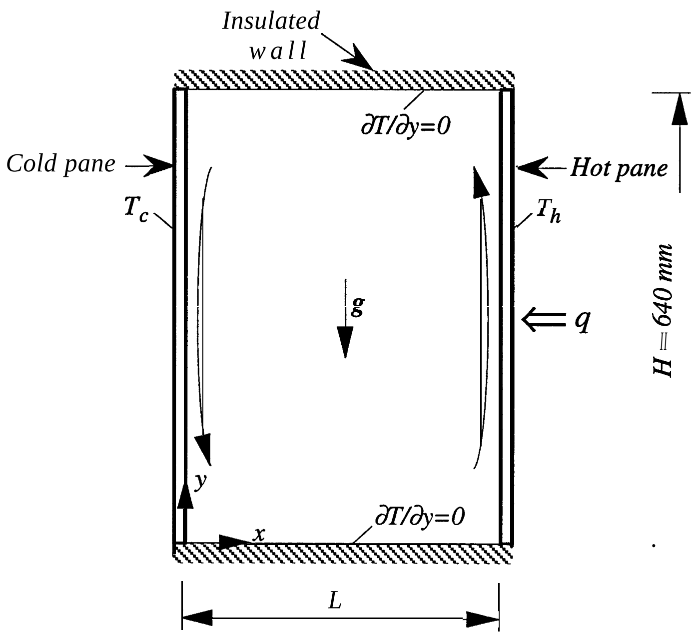

Figure 1. The physical model under consideration

Numerical calculation

The flow inside the enclosed space is assumed to be steady, laminar, incompressible and two-dimensional. Viscous dissipation is neglected and all thermo-physical properties of the fluid in the enclosed space are assumed to be constant, except for the buoyancy term of the y-momentum equation, i.e the Boussinesq approximation, see Gray et al [5]. There are no radiative processes between the surfaces. Considering the above mentioned assumptions the following governing equations are obtained.

Equation of the conservation of mass

$$\partial u/\partial x + \partial v/\partial y = 0 \tag{1}$$

Equation of the conservation of the momentum

$$\rho(u\partial u/\partial x + v\partial u/\partial y) = -\partial p/\partial x + \mu(\partial^2 u/\partial x^2 + \partial^2 u/\partial y^2) \tag{2}$$

$$\rho(u\partial v/\partial x + v\partial v/\partial y) = -\partial p/\partial y + \mu(\partial^2 v/\partial x^2 + \partial^2 v/\partial y^2) + \rho g\beta(T - T_{ref}) \tag{3}$$

Equation of the conservation of energy

$$\rho c_p(u\partial T/\partial x + v\partial T/\partial y) = k(\partial^2 T/\partial x^2 + \partial^2 T/\partial y^2) \tag{4}$$

For faster convergence of the numerical solution the governing equations are solved in a dimensionless form. These following dimensionless parameters are introduced.

$$x^* = x/L, y^* = y/L, \ T^* = (T - T_{ref})/(T_h - T_c), p^* = p/p_{ref}, u^* = u/u_{ref}, v^* = v/u_{ref}$$

Where $T_{ref} = T_c, u_{ref} = \alpha/L, p_{ref} = \mu\, u_{ref}/L$. By using the proposed parameters, the dimensionless governing equations are derived as:

Conservation of mass

$$\partial u^*/\partial x^* + \partial v^*/\partial y^* = 0 \tag{5}$$

Conservation of momentum

$$1/Pr(u^*\partial u^*/\partial x^* + v^*\partial u^*/\partial y^*) = -\partial p^*/\partial x^* + \partial^2 u^*/\partial x^{*2} + \partial^2 u^*/\partial y^{*2} \tag{6}$$
$$1/Pr(u^*\partial v^*/\partial x^* + v^*\partial v^*/\partial y^*) = -\partial p^*/\partial y^* + \partial^2 v^*/\partial x^{*2} + \partial^2 v^*/\partial y^{*2} + Ra\, T^* \tag{7}$$

Conservation of energy

$$u^*\partial T^*/\partial x^* + v^*\partial T^*/\partial y^* = \partial^2 T^*/\partial x^{*2} + \partial^2 T^*/\partial y^{*2} \tag{8}$$

By comparing the governing equations with the dimensionless form of the governing equations these relationships are obtained

$$\rho = 1/Pr, c_p = Pr, \ \beta = Ra\, Pr, \ k = 1, \ g = 1, \ \mu = 1$$

Where

$$Ra = \beta\, g\, (T_h - T_c)\, L^3/k\, \alpha\, \upsilon, \ Pr = \upsilon/\alpha \tag{9}$$

Boundary condition in dimensionless form

On the hot pane	$u^* = v^* = 0, T^* = 1$
On the cold pane	$u^* = v^* = 0, T^* = 0$
On the insulated walls	$u^* = v^* = 0, \partial T^*/\partial y^* = 0$

The finite element code FIDAP, is used to solve the governing equations, see [6]. Non-uniform grids are used in such a way that grids points are placed at geometrically decreasing distances in the regions next to the walls, where large gradients of velocity and thermal gradients are expected. Grid refinement is applied to check the accuracy of the solution. A number of grid systems, eg. 20×100, 30×100 and 40×200 are considered and the grid system of 30×100 nodes is used for the solutions presented here for aspect ratio 40, as a trade-off between accuracy and efficiency. The demand for convergence of the solutions of temperature, pressure and velocity is when the difference between the iterations is less than 10^{-3}.

Numerical results

The results presented here are interesting for window constructions. Attention is focused on the effect of the Rayleigh number, *Ra,* based on the width of the cavity and aspect ratio of the cavity, *A,* and on the thermal behaviour of the gases within the cavity. The numerical results presented here are obtained for Rayleigh numbers, *Ra,* up to 20000, and aspect ratios, *A,* varying from 40 to 130.

The figure below shows results from a numerically calculated case where the Rayleigh number is 12000 and the aspect ratio is 20. The results, which are presented here, are the isotherms and the streamlines in the cavity; also the velocity at the top of the model are presented, see figure 2.

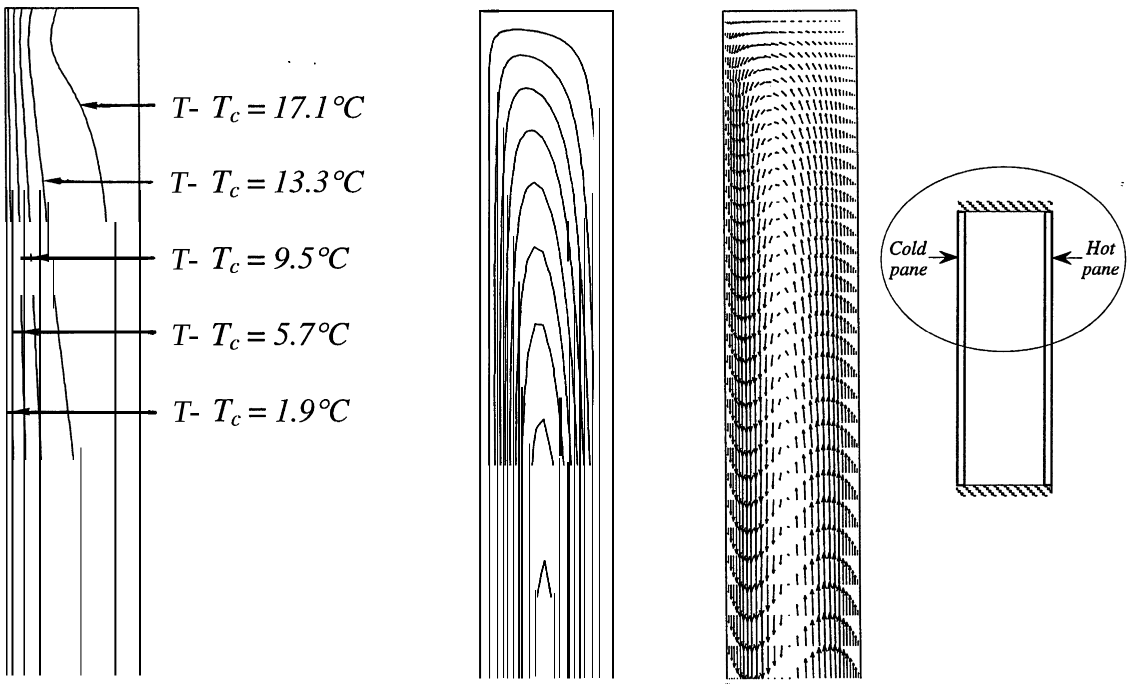

Figure 2. The predicted isotherms, streamlines and velocity for case Ra=12000 and A=20

To ensure the results from the numerical simulations of the model are reliable the results have been validated (see table 1) with measurements from Elsherbiny [1]. In addition, the predicted results are compared with the results obtained theoretically by Batchelor [3] and numerically by Schweiger et al [4] for aspect ratio 40 only, for further validation of the present numerical simulation. When Elsherbiny made his measurements he regulated the Rayleigh number,. *Ra*, by changing the density, p, with different pressure inside the enclosed space. Only calculations for atmosphere pressure were considered in the present study for numerical simulations. Therefore only measured values for aspect ratios, *A*, up to *A* = 40 were used, for higher aspect ratios in atmospheric pressure Nu = 1 which means that there is no convection in the enclosed space.

The mean Nusselt number over the whole height of the cavity is obtained by

$$Nu = \frac{1}{k \cdot \left(H/L\right) \cdot (T_h - T_c)} \int_0^H q \cdot dy \qquad (10)$$

Case	*A*	*Ra*	Nusselt number, *Nu*			
			ref.[1]	ref.[3]	ref. [4]	present study
1	5	2610600	8.374	12.637*	-	8.279
2	10	343250	4.417	6.399*	-	4.367
3	20	37970	2.200	3.103*	-	2.063
4	40	5765	1.062	1.200	1.100	1.083
5	80	4000	-	1.070	-	1.038
6	120	4000	-	1.046	-	1.019

* *Pr = 0.7*

Table 1. Validation of the Nusselt number, Nu

When there is only one flow in the enclosed space, which means there is no secondary flow in the space, the Nusselt number is constant except at the top and at the bottom where the flow turns. In this regime, there is only conducting heat transfer and it is therefore called the conduction regime. The next regime is called the boundary layer regime and in this regime the heat transfer endures through the enclosed space both conducting and convection. Here the Nusselt number is not constant all over the enclosed space. The local Nusselt number decreases along the hot pane and because of that the Nusselt number must be measured all over the space. Elsherbiny measured the average Nusselt number over three areas and these three average numbers form a total average number for the whole space..

The Nusselt numbers along the height of the hot pane as a function of, *Ra*, for *A = 40* are shown in figure 3. The graph shows the numerically predicted local Nusselt numbers and the triangle stands for the measured average Nusselt numbers over the three areas. One reason for the difference between the measured and the simulated results for *Ra* = 5765 was that the value was measured over an area and then an average Nusselt number has been calculated over this area.

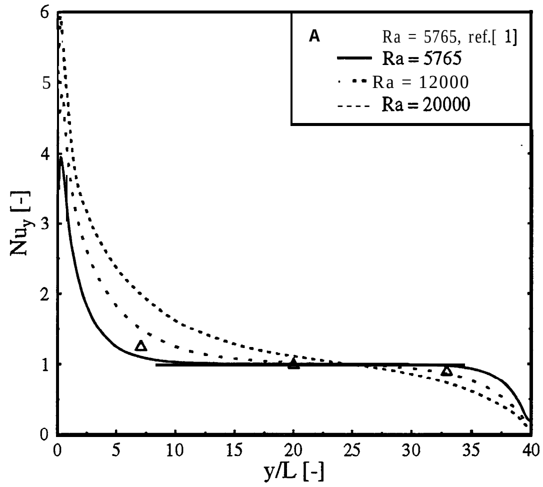

Figure 3. The local Nusselt number along the height of the heated wall

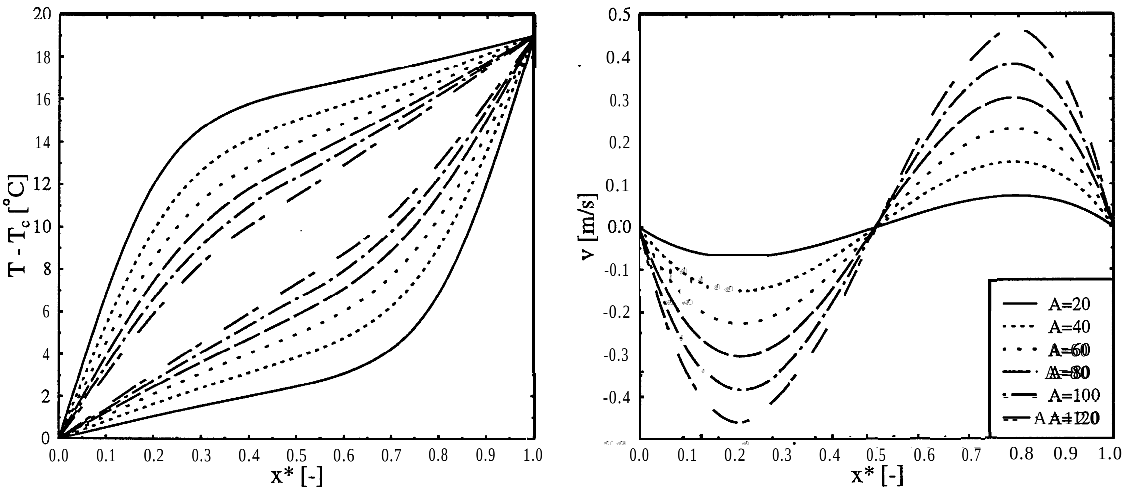
If the Rayleigh number, *Ra,* is constant and the aspect ratio varies, convection heat transfer will change within the enclosed space. When the aspect ratio decreases (the width of the enclosed space increases) the convective heat transfer increases.

Figure 4a presents temperature gradients at heights y = 30.5 mm and y = 609.5 mm. The Rayleigh number, *Ra,* is 12000. The figure shows that when the aspect ratio decreases from *A* = 120 to *A* = 20 the temperature gradient declines gradually, which shows that convection rises with the space width. The figure also shows that the temperature gradient is inversely symmetric at the two heights.

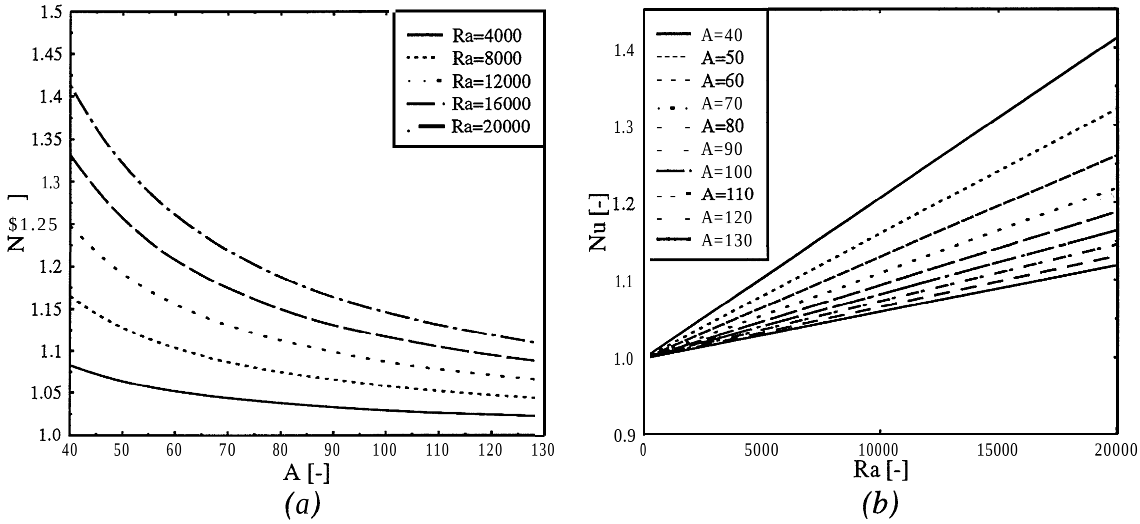


0 *a* (*b*)

Figure 4. Temperature gradient at y = 30.5 mm, y = 609.5 mm (figure 4a) and velocity profile at y = 320 mm (figure 4b) for different aspect ratios.

Figure 4b shows that when the aspect ratio, *A*, increases, the velocity, v, in the enclosed space will also increase. On the side where x^* = 1 (the hot pane) the gas rises while on the side where $x^* = 0$ (the cold pane) it falls. The velocity curves are inversely symmetric at $y^* = 0.5$. The figure 4b shows the velocity in the middle of the height (y = H/2) at a Rayleigh number of about 12000.

Figure 5 shows that there is a dependence between the Nusselt number, *Nu*, and the aspect ratio, *A*, the dependence of the Rayleigh number on the Nusselt number, Nu, is showed in the figure. Figure 5a presents the Nusselt numbers for aspect ratios from *A* = 20 to *A* = 120 at Ravleigh numbers up to *Ra* = 20000. Figure 5b displays the same results as figure 5a bu. the graph is made for Nusselt numbers against Rayleigh numbers.



Figures 5. Variation of the Nusselt number as a function of the aspect ratio (figure 5a) and Rayleigh number (figure 5b).

The main goal of the present study is to obtain a correlation for the rate of heat transfer, Nu, as a function of *Ra* and *A*, over the range of values that are of practical interest in window applications. According to figure 5b the best-fitted expression, which represents the numerical results, has the following form:

$$Nu = 1 + C_1 \cdot A^{C_2} \cdot Ra^{C_3} \quad (11)$$

Where C_1, C_2 and C_3 are 0.00137, -1.137 and 1 .OOO respectively. The coefficients are in good agreement with those proposed by Batchelor [3].

Case	C_1	C_2	C_3	Limitations
Present study	0.00137	-1.137	1 .000	$40 \le A \le 130,\ 0 \le Ra \le 20000$
Batchelor [3]	0.00 139	-1.000	1 .000	$A > Ra/500$

Table 2. Coefficients to equation 11

The gases suitable for window constructions have a Prandtl number, *Pr,* which varies from 0.6 to 0.8. Numerical calculations for *Pr* from 0.5 to 1.0 have been performed with constant Rayleigh numbers and the results from these calculations indicate differences smaller than 1%, which means that the Nusselt number is independent of *Pr,* when the Rayleigh number is specified.

Conclusions

An investigation was made to provide better understanding of the mechanism of convection heat transfer in a rectangular enclosure by means of numerical method. The analysis covers the range of values for aspect ratio, *A,* and the Rayleigh number, *Ra,* which are of practical interest in window construction.

For laminar natural convection within the cavity, the Nusselt number, *Nu*, according to the numerical predictions presented here is proportional to the, A^{C_2}, and Ra^{C_3} where C_2 is -1.137 and C_3 is 1 .O, respectively, for the interval $40 \leq A \leq 130$ and *Ra* up to 20000. The proposed correlation for, Nu, is unique because it covers the geometry and fluid properties as well as boundary conditions which are relevant for thermal analysis of window construction.

The predicted results are in good agreement with the results obtained theoretically and experimentally as well as numerically by other researchers.

Thermotropic layers to provide shading for outside walls

H. Goedeke
Fraunhofer Institute for Building Physics, Holzkirchen and Stuttgart, Germany
(Director: Prof. Dr. Eng. habil., Dr. h.c. mult., Dr. E.h. mult. Karl Gertis)

Abstract
In modern architecture glazing structures for walls, roofs, green houses or malls are common. To avoid moisture condensation and heat losses in winter periods, they have to use Low-E glasses with shading devices to prevent an overheating in the summer. Such shadings with blinds inside or outside are expensive to construct, to work and to. serve. An alternative system is under consideration of all these criterions, with the method of Quality Function Development (QFD), patented: a glazing with a thin layer of a thermooptical polymer as adaptive shading (TOPAS). Such a system is transparent in winter for a higher solar energy gain and opaque in summer periods to reduce the energy transmission. The switching temperature can be influenced and therefore calculated for different use in orientation, locality of the building and favourite climatic conditions inside for human comfort. Prototypes of such thermotropic glazings are in analysis and in production.

Keywords:
adaptive shading, overheating, solar protection system, thermotropic glazing, TOPAS

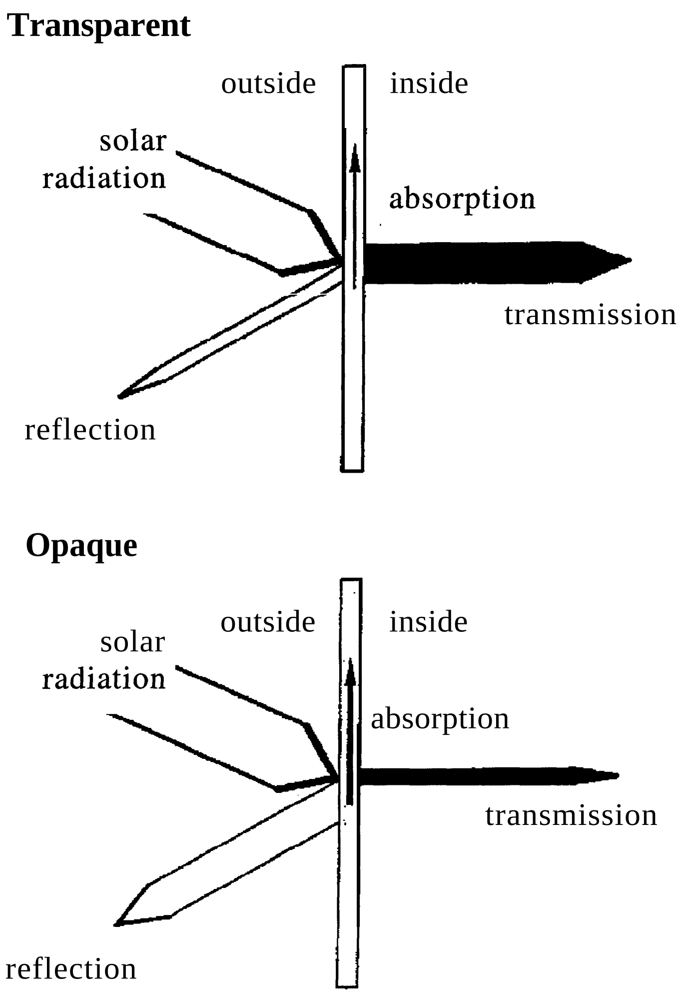
1. Introduction

Taking today's energy costs into account, the utilization of the potential building-heating savings offered by the employment of passive solar energy via transparent building materials in outside walls is extremely restricted. The economical usefulness of this "additional heating source" is decisively influenced by the solar protection system employed. Traditional "mechanical" solar protection devices such as roller-blinds, awnings etc., which are used to prevent the overheating of interiors in summer, are cost-intensive because of their complicated construction, control, regulation and maintenance requirements. In many cases, such systems can only be employed to a limited degree, e.g. when shading overhead glazing or large areas of translucent roofing.

A simple thermotropic shading system in the form of a pure polymer layer in the glazing or the transparent façades could eliminate the cost disadvantage.

The reversible shading mechanism of thermotropic layers is based on the reduction of transmission as temperatures rise. When the temperature of the outside air is low, solar energy can penetrate the transparent layer. But when the temperature of the outside air is high, e.g. during the bright summer months, a large proportion of the solar radiation is reflected by the layer. Fig. 1 is a schematic representation of radiation penetration in the case of such a thermotropic system.

Fig. 1
Schematic representation of radiation penetration through a thermotropic system



Materials consisting of a mixture of polyether and water, encased by an aqueous layer of vinyl carboxyl gel and applied to the interior of the double glazing, have been known since 1985 [1] and developed by the Fraunhofer Institute for Building Physics. Problems connected with the sealing of the edges and the application techniques led to new considerations involving the replacement of the aqueous gel system by an easy-to-apply, thermotropic polymer layer system.

2. Materials approach

The opacity mechanism is based on the existence of two phases above a defined opacity-production temperature with differing optical density. It has already been pointed out in scientific publications that partially mixable systems may exercise a thermotropic function. Partially mi.xable systems have a thermodynamically metastable range which may be utilized as a thermotropic opacity-production mechanism. These metastable systems, however, generally exhibit a high opacity-production temperature [2].

Investigations showed that the phase separation of completely segregating systems can also be used to generate thermotropic opacity [3]. These systems are characterized by the fact that the generation of opacity is not attributable to any chemical connection between the two phases. The effect is, rather achieved via the differing temperature dependence of the refractive index of the two phases, which are always present separately. Primarily, preference is to be given to globule-segregated systems containing a component which, due to a change in modification or conversion of phase, exhibits a strong discontinuity in the course of the refractive index, dependent on temperature.

Since the molecular vibrations of a substance increase as the temperature rises, its optical density diminishes and the refractive index falls. If a change in phase or modification occurs during a change in temperature, this can be mirrored by a strong change in optical density. If a Substance A is mixed with a Substance B exhibiting such a change in structure, a difference in refractive index may occur leading to a diffusion of the incoming radiation. The number, size and geometry of the diffusion centres B and of the difference in the refractive index are the parameters which determine the reflection and transmission properties of the mixture of substances.

Various alcohols, ketones, esters, aromatic and aliphatic compounds as well as carbonic acids exhibit a change in modification or phase within the above-mentioned temperature interval. Fig. 2 shows the refractive index n_D in dependence on the temperature for a few selected monomers. As the course of the graph for the aromatic compound clearly shows, a phase transformation does not inevitably lead to a stepwise course of the measured line, as this is essentially dependent on the structure which forms. Both the selected carbonic acids and the aliphatic compounds are characterized by a clear, structure-dependent modification of the optical density. The aliphatic compound shown in Fig. 2 exhibits the greatest difference in refractive index at phase transformation of all monomers investigated, and should thus be suitable as a thermotropic component.

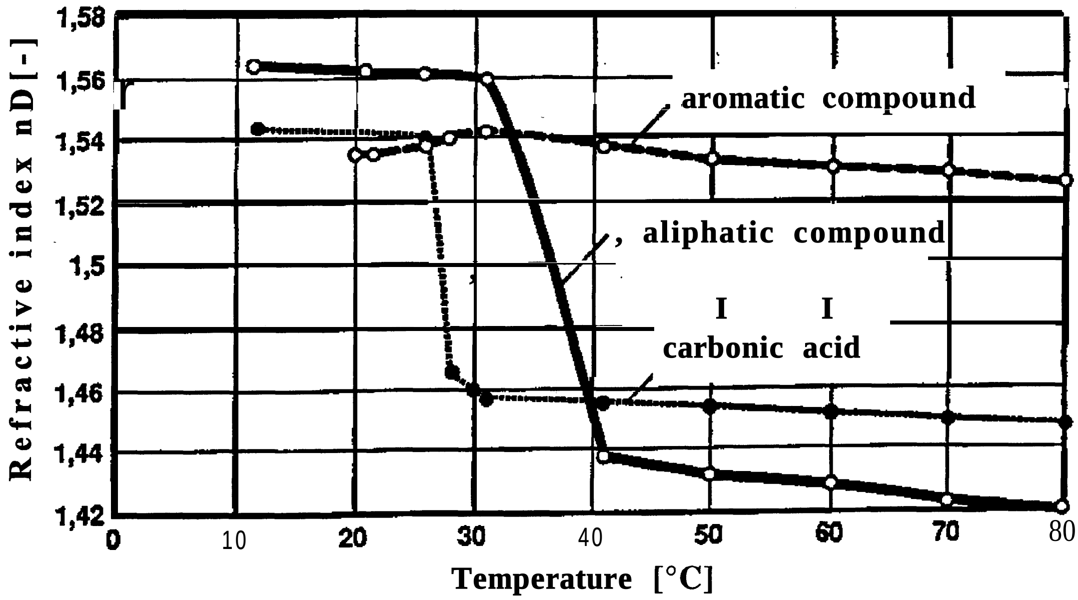


Fig. 2 Refractive index of selected organic monomers in dependence on temperature

By selecting a corresponding class of polymer, the refractive index n_D^{20} of the matrix polymer can be adjusted within a range of 1.48 to 1.60. The use of PES matrix systems is recommending in combination with this aliphatic compound.

3. Production

Starting with the aliphatic compound and a UV-curable polyester, a solution is formulated with the help of a reactive solvent. The easy flowing solution can be poured into to the interior of a double glazing, consisting of a cheap selfadhesive spacer as temporary sealant, using established application techniques. In the next step a quick UV-curing process takes place initiated by a short UV-exposure. Thermotropic layers approx. lmm thick are produced.

When the layer is being formed, the curing conditions determined by time, temperature and intensity of the radiation exercise a strong influence on the radiation-related properties of the thermotropic layers. This is determined by the size of the crystals of aliphatic compound forming within the layer, their distribution within the matrix structure and the possibility of nucleation as re-crystallization of the liquid monomer globules begins after their temperature drops below precipitation level. Fig. 3 shows a photograph of two glass sheets laminated with a 1 mm thick thermotropic layer, the left-hand half of which has become opaque after exposure to a current of hot air of approx. 40°C.

Fig. 3 Photograph of a thermotropic glazing consiting of two glass sheets with a 1mm thick thermotropic TOPAS-layer. (Geometry of sample approx. 700 x 700 mm)

4. Properties

The opacity produced by the change in modification in the case of the thermotropic layer developed can be quantified on the basis of the rectified-hemispherical transmission. Fig. 4 shows the rectified-hemispherical transmission in the wavelength range-from 380 nm to 2250 nm for a layer at two different temperatures. The degree of light transmission is lowered by the reduction of transmission from 0.86 to 0.43.

The degree of radiation transmission is reduced from 0.84 to 0.55. As the measured lines show, no distinct bands of absorption occur in the wavelength range of global radiation. Accordingly, these layers are purely reflecting systems which can be expected to exhibit corresponding values in their overall degree of energy permeability. These investigations are at present being prepared, utilizing a newly developed calorimetric g-value testbed.

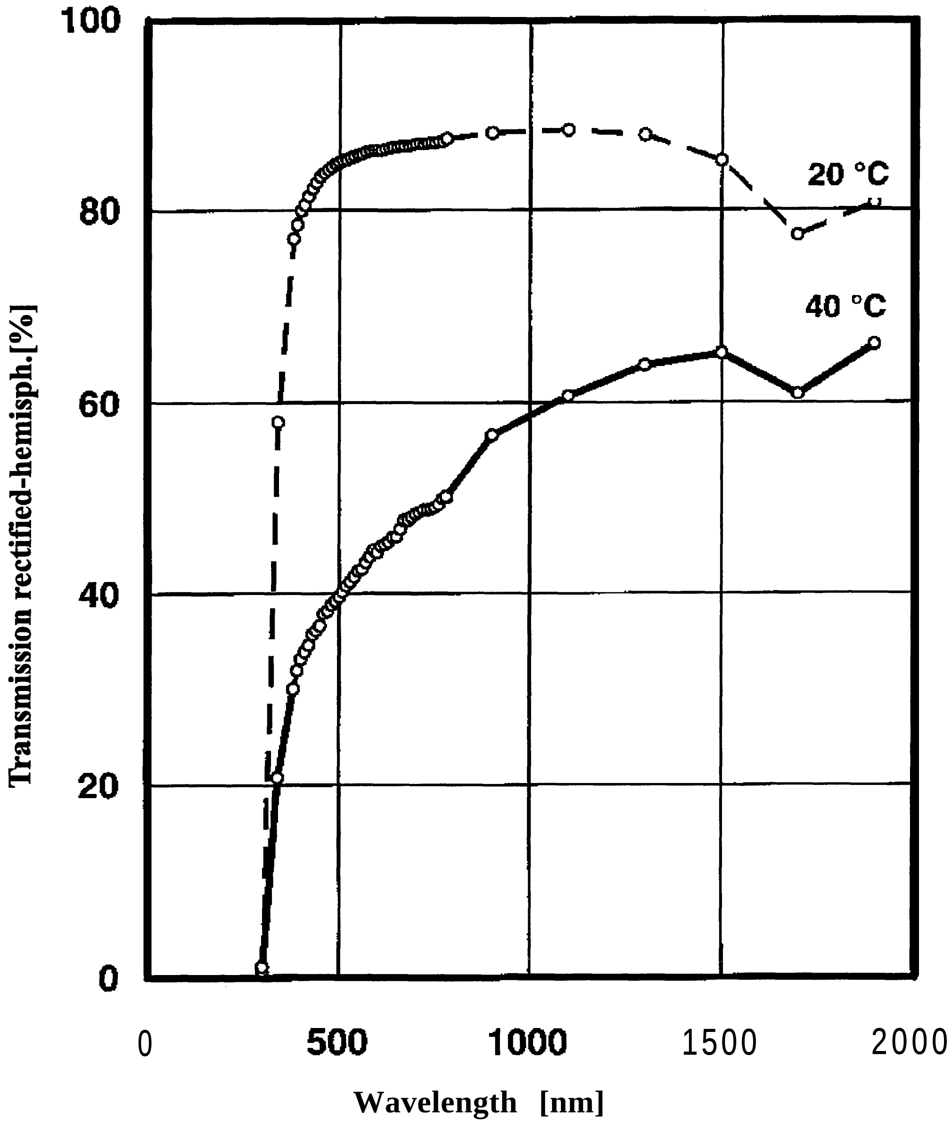

Fig. 4 Rectified-hemispherical transmission of a thermotropic coating at temperatures below and above the opacity-formation temperature.

Boundary conditions:
Layer thickness approx. 1 mm
Oacity-formation temperature 35°C

As ageing investigations show, the embedding of the thermotropic components in the polymer matrix plays a decisive role in resistance to ageing. In order to exclude the influence of any ageing processes and to further develop the product into a industrially usable commodity, a combined project with glass and coatings manufacturers, also including the paint-chemicals industry, has been initiated.

Assessment of a hybride heating system with ventilated concrete ceiling

N. König, D. Oswald
Fraunhofer Institute for Building Physics, Holzkirchen und Stuttgart, Germany
(Director: Prof. Dr. End. habil., Dr.h.c. mult., Dr. E.h. mult. Karl Gertis)

Abstract
To reduce the energy consumption in buildings we developed a heating system with a solar air collector and ventilated concrete slabs in the ceiling, so this heavy building part is the heat storage on sunny days in the afternoon, and we can restore in the evening and night in nothern part of the building the solar gains. Such systems can also be used for summer cooling.
To restore the heat by air ventilation, the tubes in the ceiling are in contact with the room air, so we have to avoid dust and mould growing in the slab with filter systems and in advance by correct design calculations: for different constructions of dimensions, air conditions and insulation in the critical zones of the ceiling (near the collector- adapter) we calculated the risk using a fuzzy transfer function for the probability of mould growing. The calculated energy reduction in the winter period for the hybride system was about 10 to 25 %, compared with traditional fuel heating. In two winter periods the measurements in practice showed a reduction of 11,4 % with an efficiency ratio of hybride gains to solar radiation on the collectors of 15 %.
To get a rent of invest the system components must be simple enough or with double function like the ceiling slab: in the model case with the investigated small l-family house the additional costs for the whole hybride system were about 55000 DM or 4600 DM per m² installed collector area. Compared with the area specific heat consumption of 94 kWh/m²a and the hybride solar gains of about 1 MWh/a the hybride system is as a prototype working very well, but too expensive. But there is a greater potential for rationalization in multi- family houses and when the solar collectors are integrated in a facade system between the windows of the different floors.
The compatibility of new technology, energy reduction and thermal comfort could be measured in the experiments by air exchange rates in sunny winter and summer periods. The indoor air temperatures were in comfortable behaviour and supplemented by direct gains through windows in the afternoon and by the hybride system in the night.This investigation shows that the pre- calculation about modelling of the hybride system gave a sufficient prediction of indoor air temperatur and reduction in energy consumption, so we have some advices for further developments.

Keywords: energy consumption, hybride air heating system, mould risk, solar collector, system costs, thermal behaviour (IAQ), ventilated concrete slab.

1. Introduction

To reduce heat energy consumption in buildings the heating system shall be transfer quick enough the needed amount of heat to make each room comfortabel in temperature and air distribution. In high insulated buildings there are often problems of overheating in the seasons with great solar radiation as direct gain through windows and in the summer due to internal loads. Wall or ceiling elements can be made hollow to reduce the weight and to keep the static stability with air tubes in e.g. leightweight concrete slabs. In combination with an air heating systems, which is easy to regulate, we can ventilate the ceiling or floor element with warm air from a solar collector on the outside of the building in winter or with cool air from underground or northern parts of the building. Such combinations of building and technical equipment are named „Hybride systems" and investigated in IBP by modelling the insteady heat storage and laboratory experiments on different ventilated wall and ceiling components [1,2]. The validation of such a system was investigated to the problem of mould growing in the ventilated components with all the influences of condensation, dust, temperature and moisture content by a lot of laboratory tests and calculations using fuzzy transfer function to avoid or reduce the health risk [3]. Experiments in an one-family house in Zaberfeld nearby Stuttgart are running about a time period of 1,5 years: the results in the reduction of heat energy, thermal behaviour and cost relations are reported.

2. Building and hybride system

The building was installed in 1995 according the data of the optimization calculations e.g. for the ventilated tube diameter (100 mm) in the concrete ceiling (36 m^2 equivalent 6 m^3), the dimensions of six solar air collectors or the air velocity for charging and discharging modes, see Fig. 1. There is also a scheme of the ground-plan (82 m^2) and the air flow from collector on the south wall through the ceiling to north side and back in a closed circuit. Between two charge tubes is one discharge tube, which is an open circuit to the living area for active, ventilator supported mode. The eastern part of the building is built up as a passive storage ceiling without separate discharge ventilators. The complete data about the hybride components and the building are given in [4] and some important values are added in Tab. 2.
The house is occupied by 2 persons since 1995 and the measurement equipment recorded each hour all the relevant data of the additional electric heaters, the condition of collectors, ventilators, heat storage in the ceiling, the room temperatures and the weathering.

3. Experimental results

For the heating periods of November 1995 till May 1996 the monthly temperatures and solar radiation conditions on the outside of the test building are reported in Tab. 1 with the energy balance between gains and losses due to transmission through building parts and air ventilation. The heating consumption depends on the natural fluctuation of the climate and is standardized in [4] to european test reference year (TRY). The original electric heaters in each room installed as night block storage elements are too inert: the

gains due to the hybride system (3 %, Tab. 1) were reduced from an overheating in the rooms, so we changed the elements to electric direct heaters in summer 1996. Then the efficiency of the solar collector in combination with the ventilated storage ceiling could be higher in the total period to 6 % and in maximum to 11 % (Oct. 1996). The distribution of the different parts in the gains and losses are shown in Fig. 2 for both heating periods. It is evident, that only in the months with higher solar radiation (e.g. in march on 19 days at noon > 500 W/m²) the hybride system is working well and the ventilators are running. The area specific heating energy was calculated with 94 kWh/m²a not in the level of a german „Low energy house“, but lower than the allowed government requirement (3 years ago) of 100 kWh/m²a for an A/V-ratio (1,2 m^{-1}) of this building. The efficiency of the hybride ventilated ceiling in relation to the solar energy in the collector is about 15 % over the period 1996/7 and can be optimized because the rate of internal loads and the room air temperature (14 kWh/m² and 22 till 25 °C) were much higher with our people in the test house than the statistical average.
To reduce the consumption of energy for the 12 ventilators (2 at each collector in each charging tube) and the noise in the room we used an air velocity in the tubes of 1,8 or 0,8 m/s: then we can gain 12 or 7 kWh per day with a solar radiation of 4 kWh/m².
The charging of the ceiling with warm air from the collector started at a solar radiation of > 200 W/m² and got a maximum in collector temperature of 50 °C (march 1996; 0,8 m/s) and of 35 to 48 °C in the ceiling near the air entrance. The temperature in the nothern part of the ceiling (tube redirection) was at 23 °C and below under the wanted 26°C, when an active discharging of the concrete storage is regulated. This can be reached with the higher air velocity in the tubes, but the occupant don’t want this mode although the noise of the hybride ventilators is below 35 dB(A), which is acceptable.

4. Assessment, validation and economy

According to the calculations to condensation risk and mould growing [3], we found no such problems in the separeted air circuits for charge and discharge of heat. The collector temperatures in summer were in maximum at 80 °C without shading and had no problems. A relevant part (8 %) of the solar energy is transfered through the wall between the collector backside to the rooms and influenced the direct gains and therefore the room temperatures and is lacking in the hybride energy balance (time shifted). The temperature distribution in the heated ceiling was not homogen: differences between surface and air of 15 K in south and of 5 K in north area. This can be lowered when using different thicknesses of the installed insulation under the ceiling for an active discharging.
The installation costs for the hybride system were for this small house and the production as a prototype too high to reach an ecomomic rent of invest: Tab. 2 gives the specific costs and the sum of 55000 DM without a reduction in the conventional block storage heaters (caused by the restrictions of the power supplier to dimension the units according the DIN- standard). The costs for the period 1996/7 to use environmental energy were 20 DM for ventilators electric power to earn from the sun an equivalent of about 900 kWh electricity or 225 DM. This unfortunately is not in an economic range, so we have to opimize the system in changing the additional heaters to small, cheap units, modification of the insulation layers, integration of window air collectors instead of separate wall element collectors and use of the hybride heating

system in buildings with a great amount of industrial prefabricated components perhaps in multi- store constructions.

5. Conclusions

The measurements in an one- family house over two heating seasons and a summer period have shown a sufficient agreement between predicted calculated temperature and heat energy distribution in hybride building components and the total reduction in heat energy consumption to fulfil1 a good thermal behaviour. Some potential could be identified for a further development and a better rent of invest in multi- store houses. Then we expect for such a heating system with a short- term concrete storage between the floors to transport the too much solar energy from south to north rooms a good chance.

Value of indoor air quality to productivity

G. Flatheim, M.Sc., FLATHEIM A/S, Stavanger, Norway, Indoor Environment Consultant

Abstract

Researchers and others in many parts of the world have become aware that the productivity is dependent on a good indoor environment. The expression Indoor Air Quality (IAQ) seems to be replaced with Indoor Environment Quality (IEQ).

In most buildings in the service industry wages and wage-related costs represent 8590% of the total costs per workstation, and the increase in value is completely dominating the total economy. Our most important challenge in planning new and refurbishing old buildings is to create an excellent environment for productivity as well as for comfort.

Today we have an extensive knowledge of the most important factors in the total environment. In Norway we call them the "Environment's 7 sisters", including thermal, atmospheric, acoustic, actinic, mechanical, psycososial and aestetic environment. Good results depend on willingness to use this knowledge and build up competance, which contains knowledge, insight, behaviour and attitude from all persons involved in the building process.

In the USA and in Norway there have been some studies since the late 1980s concerning productivity related to indoor air quality and the indoor environment [1, 2, 3]. The most comprehensive was carried out by Dorgan Associates, Inc., prepared for National Energy Management Institute in USA (NEMI):

"The conclusion of this study is that improving indoor air environment will provide a high return on investment through productivity gains, health savings and energy reductions.

This paper will describe the preparation of an environmental plan for a new project including the "clean building philosophy" (CBP), energy efficiency and building procedures and show that this is good strategy.

Keywords:clean building philosophy, environmental plan, indoor air quality, productivity, total costs.

1 Introduction

An important factor in today's building industry including rehabilitation of existing buildings, is the owner's attitude towards contractors and all building workers and towards the users of the building after occupation. If, before starting the design work, the owner has insight in total economy and decides that he or she wants a clean and tidy construction site with no accidents during the construction period and good indoor air quality for the users, it is highly probable that he or she will obtain a good result. But it is also essential that in-house qualifications can cope with external architects and consultants, chosen as professionals rather than friends. The building owner must behave professionally and have in mind the final result and the total economy per work station. Financial understanding is necessary, and it must be understood in full that annual costs are dominated by wages and wage-related costs. An excellent indoor air environment including air quality and climate requires the best consultancy, both from architects, civil, electrical and HVAC (heating, ventilating and air conditioning) engineers.

It is documented that a rise in productivity of approx. 0.6 % in office buildings may justify a rise in investments for the HVAC system of about 60 %, according to Haukenes [1]. Totally this means that a good strategy for healthy buildings start with the owner's philosophy concerning the new project.

2. Environmental plan

A part of the important attitude is preparation of an environmental plan. This might be a good strategy. The purpose of such a plan is basically to define the environmental objectives of the project, considering the working environment and the environments.

A principal objective is to create a standard for internal environmental quality, including the amount of the best possibly filtered outside air, choice of heat recovery system and building materials, equipment, furnishing, carpet quality etc. The main goal is to obtain the best internal environmental quality including indoor air quality, thermal, acoustic and lighting environment. Both the design of the mechanical environment and aesthetic factors are important parts of an environmental plan, also including work-stress and psychological factors of different kinds.

Pilot Study on Indoor Air Quality and Climate - a [1]NATO/CCMS project including USA/Canada and 14 countries in Europe - has given us comprehensive knowledge of the most important elements in an advanced environmental plan. To maximise internal air quality during a building's lifetime one must include a plan for cleaning procedures and maintenance to prevent a negative influence on the indoor air quality after occupancy. For example, contents of organic dust can cause asthma and allergy, and the maximum of efforts must be made during the environmental planning period to reduce such (and other) contaminations.

Consultancy has for decades been focused on low investment costs - and later in addition on energy consumption. After the oil embargo in the mid 1970s, several energy conservation efforts have had a negative impact on the indoor air quality. This very unfortunate situation is about to be changed because of better documentation about the health effect of an adverse indoor climate.

---

[1]NATO/CCMS - NATO/Committee of the Challenges of Modern Society

3. The “clean building philosophy” (CBP)

Implementation of a building project which employs new or innovative techniques requires the total cooperation and participation of sub-contractors. Accordingly, great emphasis is placed on the education of contractors and the displacement of conventional attitudes and practices. Unless individual workers can be convinced of the basic value of following “clean” construction procedures, there is no possibility of achieving one of the principal objectives of the original environmental plan, which was made for Tranberg College in Gjoevik and the Lysaker Market in Oslo West, Norway.

In summary, it can be fairly stated that these projects, while conventional in many respects, were carried out with a sensitivity to environmental issues which is quite new in planning in Norway. The main goal was to create educational conditions that will give no objective reasons to complain about the indoor air quality and climate - or the indoor environment.

The following areas were identified as having a potential effect on air quality for people, especially for children and female office workers:

- Dust and particulate matter generated during construction/reconstruction
- The quality and design of air handling equipment
- Maintenance procedures
- Selection of interior building materials and furnishings
- Emissions from office equipment, e.g. copy machines and laser printers

4. Control of contaminants

In response to the foregoing, the following specific measures were implemented for control of dust and other particulates contamination during the construction phase of the projects:

- All interior concrete surfaces to be spray-painted to minimise concrete dust and the smell of cement
- All wall penetrations for duct-work, cable runs, etc. sealed to avoid cross-contamination of building areas by dust/particulates
- All carpeting sealed off with PE-coated paper until all dust-producing construction activities is completed
- All duct-work sealed prior to delivery and after installation until just before start-up
- Use of vaccum cleaner to systematically remove accumulating construction dust and debris - daily and weekly
- All mineral wool insulation materials isolated from any contact with ventilation air, according to Hedge et al. [4]

The standardised air handling units (AHU) (Fig. 1) have been designed and equipped with a number of innovative features to maximise air quality and worker comfort, i.e.:

- No recirculation of air is employed to allow for a continuous purging of the building interior with filtered outside air

- Cross-connections between inlet and outlet duct-work are not allowed so as to eliminate possible "feedback" of contaminated air
- Two-step filtration - in air inlet and after the fan in the AHU - and possibility for a third step - HEPA or adsorption filter

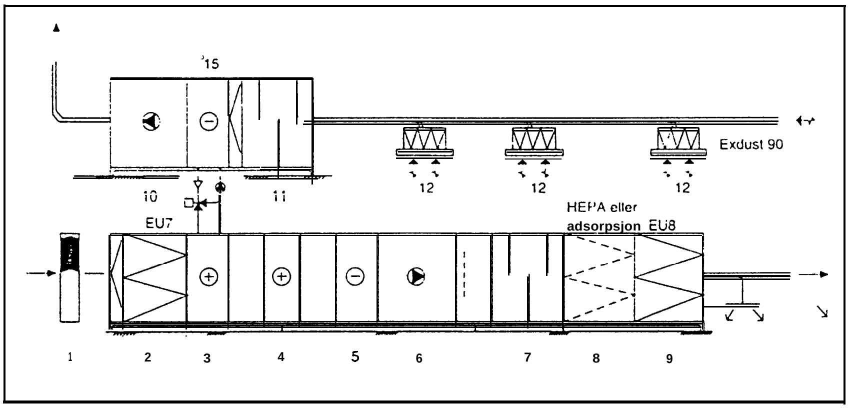

Figure 1. This figure shows an recommended AHU with EU-7 filter in air intake (2), water-glycol heat recovery unit (3/15), heating coil (4), cooling coil (5), supply fan (6), sound attanuator (7), possible adsorption filter (active charcoal) (8) and filter EU 8/9 before duct system. To maintain capacity in exhaust-system we strongly advise co-called exdust valves (12) or EU-7 filter before the sound attanuator (11).

While the build-up of dust and aerosols can be controlled in recirculating ventilation systems with properly designed filter systems, this is generally not true of fumes and gases. It is well known that some modern building materials and furnishings give off chemical fumes and vapours, some of which have been shown to be hazardous (e.g. formaldehyde fumes from wall panel insulation materials). While threats to health was not a major concern in this particular case, it was considered an important environmental factor to install a system which provides for continuous purging of the building interior with filtered, outside air, thereby minimising the build-up of "fugitive" emissions from paints, sealants, insulation, volatile organic compounds, VOCs and even microbial gases due to moisture (MVOCs). Producers have, however, made progress in manufacturing improved materials, and today we have so much knowledge that we can "phase out" the emissison problem if we select the right materials.

5. Building procedures

While a high standard is observed in all aspects of interior design to assure maximum comfort of office workers or pupils, e.g. lighting, acoustics, humidity and temperature control, the following specific features are presented as worthy of special recognition.

Building materials are common sources of VOCs or of particles, including MMMFs. Building materials which cover large areas (e.g. ceiling tiles) may absorb contaminants from other sources and subsequently release them into the interior space (the sink-effect). Building materials is therefore carefully chosen to minimise emissions, and protect against both particle and gas contamination during construction activities.

Biological contaminants (MVOCs) have been known to contaminate buildings because of improper control of moisture, water damaged materials during transport or storage on site, sources of humidification, and because of inadequate cleaning of drainpans and cooling coils. Consideration should be given to these problems in the design of the structure, including easy access to possible sources of biological contamination for proper maintenance.

Provision of a state-of-the-art air handling system to minimise the accumulation of particulate matter and trace gases and assure a working environmentwith the maximum possible air quality (Fig. 1).

6. Energy effkiency

The “no recycle” design basis introduces a difficulty with energy loss during the colder months. The cheapest solution to the energy recovery problem in such systems, so-called “recovery wheels”, requires an interconnection between the inlet and exhaust air duct-work, according to Khoury et al. [5] and Gorman et al. [6]. Since such interconnections are also excluded by the design philosophy, an innovative solution is required. SP in Borås, Sweden has published a report in 1995, concluding that the amount of outside air has to be increased by 20 % if we prefer to use such recovery wheels [7]. This is provided by a system of indirect heat exchangers utilising a recirculating glycol-water medium.

The system provides 52 % recovery of exhausted heat under design conditions, and requires no physical connection between clean and contaminated air streams. The fact that recovery wheels offer a much less costly alternative serves to illustrate the “environment first” philosophy employed throughout the project.

Inadequate supply of outdoor air to occupied spaces in offices, kindergartens and schools is a common cause of indoor air quality complaints. The outdoor air ventilation rate for schools is 14 l/s per pupil or about 415 l/s per room (appr. 60 m^2/31 persons). In offices it is 4.2 l/s per m^2 + a security factor of 30 %.

7. What are total costs?

The annual costs for running a modern office building consists of the building and equipment depreciation on invested capital costs (6 %) plus operational costs, i.e. energy, cleaning and maintenance (2.7 %). When a new building is being planned, it has become common to use total annual costs as a decision-making tool. Operating costs increase relatively with the building’s age, particularly labour and energy costs.

In the past, annual costs have been evaluated per square meter floor space, related to the building costs **only** and not to the employees working in the building, representing 91.3% of total annual costs.

But why do we put up an office building in the service industry in the first place? Of course it is because there is work to be done, and this can be done in a less expensive way if the temperature feels comfortable and the indoor air quality is high. This contributes to high productivity. A good indoor air quality and the best total indoor environment are the most important factors for improving the efficiency of any staff. Total costs must be related to the sum of wage-related costs and building costs. This is shown in the Oseberg complex in Bergen (Norsk Hydro) where annual personnel-related costs per square meter are NOK 14,882 (USD[2] 1,957) (1998).

	Alternative I "IAQ std."		Alternative II "IAQ top"	
Capital costs (depreciations)	**USD 203**	8.8%	**USD 222**	9.4%
Thermal energy (HVAC)	**USD 11**	**0.5%**	**USD 11**	**0.5%**
Cleaning	**USD 21**	0.8%	**USD 14**	**0.8%**
Wage-related costs	**USD 2,081**	89.9%	**USD 2,096**	89.3%
	USD 2,316	**100%**	**USD 2,343**	**100%**

1US$ = **NOK 7.55 (10. February 1998)**

Table 1. The difference in total costs between "indoor air quality (an important part of IEQ)(IAQ) Top" and "IAQ Standard" is marginal due to wage-related costs. This example is from the oil company Hydro in their Oseberg building in Bergen, where they say that only 0.6 % increase in productivity may pay for the difference in employed IEQ standard.

The total costs of an IEQ standard, 7.5 cubic meters per square meter per hour (2.1 l/sec per person), is USD 2,316 (Table 1). If we raise the standard to 15 cubic meters per square meter per hour (4.2 l/sec per square meter) and take precautions with selection of materials, building procedures, cleaning procedures (CPB), etc., the costs will rise to USD 2,343, and the difference is mainly in investment costs: 9.4 - 8.8 = 0.6%. The personnel-related costs dominate totally (89.9 to 89.3% for the two alternatives).

8. Value of indoor air quality to productivity

In most buildings in the service industry wages and wage-related costs represent 85-90 % of the total costs per work station, and the increase in value is completely

[2] **1** USD = NOK 6.65 (**May** 1995)

dominating the total economy. Our most important challenge in planning new and refurbishing old buildings is to create an excellent environment for productivity as well as for health and comfort.

In the USA and in Norway there have been some studies since the late 1980s concerning productivity related to indoor air quality and indoor environment [1, 2 , 3]. The most comprehensive was carried out by Dorgan Associates, Inc., prepared for National Energy Management Institute in USA (NEMI):

"The conclusion of this study is that improving indoor air quality and indoor environment will provide a high return on investment through productivity gains, health savings, and energy reductions. The minimum direct annual employee productivity benefit of $55 billion is feasible by implementing a nation-wide effort to maintain indoor air quality at the level recommended by current scientific knowledge. The benefits of improved IAQ/IEQ are improved productivity, increased profits, improved employee-customer-visitor health and satisfaction, and reduced health costs.

The benefits of improved IAQ/IEQ are so large that this opportunity cannot be ignored. The challenge is to develop a sound and workable plan to implement the link between indoor air quality and productivity.

Anaverage simple payback of 1.6 years is achievable from the total productivity benefits. The improvements in many buildings will have a payback of less than 7 months. Almost all improvements to the environmental systems identified in this study have initial costs that are offset within the first two years through productivity, health, and energy benefits.

In addition to the productivity, health, and energy benefits, there are indirect, long-term, and societal benefits that have not been quantified in this study. Among these types of benefits are:

- Monetary benefits from increased profits and sales in retail buildings
- Long term societal benefits from an overall reduction in work related job stress, gains in worker health, and thus, increased worker productivity

The health and productivity benefits will offset all energy efficiency implementation requirements in buildings today. Some measures, in particular increased make-up air, could be inappropriately implemented in a manner that would increase energy use. However, the economic benefits from health and productivity gains allow the implementation of a comprehensive energy conservation design or energy management practice that reduces the total energy consumption. Energy conservation measures are no longer required to pay for themselves through a direct energy economic offset."

9. Conclusions

For years to come our most important work will be to find documentations of economic benefits of improving indoor air quality and climate. Less work should be put into calculation of the cost of absenteeism compared to productivity loss when we are at work. If you go to work and still have reduced work efficiency, it might be reasonably easy to estimate the value of indoor air quality towards productivity.

We might benefit from asking questions, like:

- What does it cost the private and public economy **not** to have an excellent indoor environment?
- What does reduced work activity while you are at work cost?
- What does it cost society when children and students have reduced learning ability due to indoor air quality and climate?

Sustainable development also means healthy building

A. Maugard, L. Bourdeau, C. Cochet
Centre Scientifique and Technique du Batiment, Paris, France

Abstract
An important dimension in the application of sustainable development principles to the building sector is that concerning health risks related to the occupation of buildings. Today we are constructing buildings that will still be used in decades to come, and the recent examples of public health crises related to buildings oblige us to adopt a cautious approach based on the analysis and management of the risks involved, and driving us closer towards the mythical “zero risk” level.

Even if water supply is also one of the potential sources, this contribution proposes to mainly concentrate on the risks related to the air and the indoor environment, where the risks are numerous and varied.

After listing the various families of contaminants and sources of contaminants that can be found in buildings, some important examples are given: nitrogen oxides given off by heating appliances and gas cookers, and also by people through cigarette smoking; chemical atmospheric pollutants, which are also found in buildings; biocontamination of the air by all families of micro-organisms present in the air; allergens associated with complex mixtures of pollutants; radon, which can be concentrated in homes.

Considering this environment that is particularly open to the outbreak of public health crises and due to the numerous uncertainties, methods for assessment and management of risks have been developed. The general principle of these methods is explained here. Assessment is based on four elementary stages: identification of the danger, determination of the relation between the dose and the effect, estimation of public exposure, and lastly characterisation of the risk. Much work remains to be carried out on these four stages before they can be capable of clearly defining the priorities for defining risk management. In this situation, the possible recommendations must be considered in strategic rather than operational terms.

In particular, it appears important to create places of exchange where building trade professionals, users and public health professionals can learn to work together to develop, with a total independence of their scientific expertise ensured by an appropriate status, monitoring and alert procedures, capacities for informing the public and the players concerned, and also recommendations to enable public powers to act according to needs and constraints.
Keywords: building, environment, sustainable development, health, comfort, risk assessment.

1. Introduction

The act of building in a context of sustainable development must aim to meet the needs of the present without compromising the capacity of future generations to meet their own needs. The analyse of the implications of this principle is both complex and difficult: complex, because the interactions between the building and the environment are numerous; difficult, because the very concept of sustainable development is variable [1].

A first dimension is that of the impacts of act of building on the use of non-renewable resources (including energy resources) and on the quantities of wastes and effluents. A second dimension is the search for a certain harmony between the built environment and the natural environment. However, another dimension, and not one of the least important, concerns the health risks related to the occupation of buildings, and even what could be called a “protective hygienism”.

As a matter of fact, against a background of increasing public awareness of risks, due to recent highly publicised issues such as lead paint, asbestos or wood dust, many people are more and more concerned about health and hygiene problems related to building.

In fact, this question should be considered in its numerous aspects, well beyond just these notable examples, firstly, because people are spending more and more time within the confined spaces created by buildings, and secondly, because the annual rate of new construction only represents an infinitely small part of the building stock and therefore around one year will be necessary to completely renew the stock. This issue of the “close ecosystem” of the man must supplement the issue of the ecosystem of the world.

Therefore the principle of precaution obliges decision-makers and scientists to anticipate the risks and to define the best way of identifying them. Food, water and air, and even electricity, are potential sources of risks. While the first two are relatively well identified, we must now try to control the other two as much as possible.

This contribution proposes to concentrate mainly on the issue of risks related to the air and to the indoor environment.

2. What are the risk factors?

2.1 The main sources of pollutants

European directive 89.106, which specifies the essential requirements for buildings and building products, indicates the families of contaminants and/or potential sources of contaminants to be considered and establishes a general framework for identifying the sources of contamination. The indoor environment, water supply, sewerage, solid waste disposal and the external environment are the various targets of the approach.

On examining the risk factors related to the indoor environment, we find that the sources are multiple and varied. Most of them are related to the quality of the indoor air [2], while another important factor concerns sources of noise (external noise or noise from another enclosed space, impacts, services plant, etc.) and vibrations. In addition, although they are not strictly considered as contaminants, lighting, air humidity and the thermal environment are some of the parameters that can influence the immediate physical environment of the occupants of buildings, and some of them can also affect the future transition of contaminants and the activity of the sources.

Contaminants that can affect the quality of air can come from the following [3]:

- building materials, particularly all those that are in direct contact with the indoor air, such as floor and wall finishes and paints.
- technical services installations such as hot water distribution systems or combustion appliances,
- furniture, fittings and hardware,
- external atmospheric sources,
- the ground on which the structure is built,
- occupation of the building (people, domesticated or non-domesticated animals, plants),
- activities inside buildings (cleaning, maintenance work, painting and varnishing, use of pesticides, cooking meals, etc.).

2.2 A wide variety of contaminants

To this variety of sources corresponds a varied list of contaminants, which we can attempt to group together as follows:

- products of the human metabolism (water vapour, body odours, etc.),
- products of combustion (water vapour, carbon monoxide, NO_x, CO,, hydrocarbons),
- tobacco smoke,
- volatile organic compounds (several hundred individual compounds included under this generic term: formaldehyde, solvents, etc.),
- viable particles and biocontaminants (allergens, moulds, bacteria, viruses, toxins, etc.),
- nonviable particles such as fibres and particles in suspension,
- radon and other radioactive substances,
- emissions from electric and electronic equipment (electromagnetic fields, ozone, etc.).

2.3 Some examples of contaminants and risks

2.3.1 Nitrogen oxides

Nitrogen oxides (NO) are among the main atmospheric pollutants [4]. In the indoor atmosphere, the main emitters are heating appliances and gas cookers, and also cigarette smoking. Note that the indoor air partly reflects the exterior air.

In a nonpolluted rural environment, the basic level is around 5 $\mu g/m^3$. Values in urban areas are very variable. The content in an indoor atmosphere are on average less than in an external atmosphere, but it is highly variable. Thus, 10 cigarettes smoked in a 30 m^3 room will lead to levels of 40 to 80 $\mu g/m^3$. Similarly, in a poorly ventilated kitchen, very high peak values can occur when the gas cooker is functioning.

The effects on health vary from reactions of acute discomfort to chronic illnesses such as asthma or chronic bronchitis. Epidemiological studies published concerning long-term exposure suggest a relation with an increasing risk of illness of the lower respiratory tract in children. The risk increases by around 20% for every 30 μg/m^3. As regards the risks to adults or the impact on breathing, the relation is less clear.

2.3.2 Atmospheric chemical pollutants

The quality of an indoor atmosphere depends largely on the nature and the concentration of indoor sources of pollution and the ventilation conditions. However, the external inputs of pollutants must not be neglected. Their contribution varies according to climatic conditions, the location of the building and the situation of air intakes in relation to external sources of pollution [5].

In France, the most representative exposure data concern offices of the tertiary sector and school and university areas; housing has been studied very little. Similarly, there is virtually no information available for public recreational buildings (theatres, cinemas, etc.) or for sports facilities (sports halls, swimming pools, etc.) although we know that the organism is more sensitive to atmospheric pollutants during physical exercise.

Despite a certain effort in recent years, many subjects remain to be examined or to be studied in greater depth. Modelling approaches appear to be promising, particularly in terms of cost, on condition that better knowledge of the interactions between pollutants and between pollutants and surfaces is previously acquired.

2.3.3 Biocontamination of air

All families of micro-organisms are present in the air: bacteria, microscopic moulds, viruses, protozoa, etc. [6, 7, 8]. These micro-organisms and their metabolites (endotoxins, mycotoxins) can be the cause of infectious diseases (Legionnaire's disease, aspergillosis, etc.), immuno-allergic disorders (asthma, hypersensitivity of the lungs, inhalation fevers, etc.) or toxinic problems. They are also some of the possible causes of the "Sick Building Syndrome" [9], whose mechanisms are still unknown.

Biocontamination of the air varies greatly with time and depends on several factors: technical factors (air filtration, water stagnation, air renewal and communication with the external air), environmental factors (indoor humidity conditions, density of occupation of the areas, presence of plants, behaviour of the building materials [10]) and climatic factors (weather conditions, seasonal variations, etc.). Since the respective influence of these different factors is not yet modelled, normalisation concerning a strategy for realistic assessment of exposure would be difficult in the present state of knowledge.

2.3.4 Allergens associated with complex mixtures of pollutants

Experimental work and epidemiological studies in recent years suggest that there may be an increasing sensitivity to biological contaminants such as allergens, under the influence of various pollutants, some of which are mainly components of urban air pollution [11].

Biological pollutants of buildings are mainly acarids (dust mites), allergens carried by animals, and moulds. Dust mites are mainly found in homes and especially in bedrooms. They can be quantified by quantitive analysis of a marker present in the faeces. Animal allergens have also been quantified, such as those of the cat, found in the dust of classrooms or shopping centres, or of the dog, or those of rodents present in litters but also in floor dust, those of cockroaches in floor dust and in kitchen cupboards. Moulds can develop inside homes on substrates of vegetable or animal origin. Biological pollution also includes bacterial endotoxins, which have been involved in the increase in asthma in housing.

There are many chemical pollutants present in rooms, which are believed to be closely linked to allergic disorders:

- NO,, present in poorly ventilated kitchens with peaks from 400 to 1000 ppb, causes accentuation of the bronchopathy induced by the inhalation of dust mite allergens. The use of gas cookers is recognised as a possible cause of the increased risk of certain respiratory symptoms in adults, such as wheezing, laboured night-time breathing or attacks of asthma.
- The concentrations of volatile organic compounds (VOC) in the indoor air are 2 to 10 times higher than those of the external air. The rates of formaldehyde are particularly high in new houses containing urea-formol foams for less than three years. A recent study showed that, for an asthmatic person, there was a significant relation between the asthma symptoms and the measured concentration of VOC.
- The ozone present in rooms comes mainly from external sources. The effects shown in humans (bronchospasms, increased bronchial hyperreactivity) are mainly found in cases of external exposure due to the associated physical exercise. Several experimental studies show greater sensitivity to the immediate reaction induced by an allergen after prior exposure to ozone.
- During SO, peaks that can be attained when using gas radiators, asthma sufferers can have a bronchospasm.
- Tobacco is a major source of many pollutants, including nitrous oxide and aldehyde oxide. Passive smoking can cause non-specific bronchial hyperreactivity and greater severity of symptoms in asthmatic children.

2.3.5 Radon

Radon 1s a radioactive gas that is omnipresent on the Earth’s surface. On disintegrating, it emits alpha particles and engenders solid radioactive offspring that attach to particles in the air, causing lung exposure during inhalation. By different physical processes, it migrates from the ground to the atmosphere, and it can accumulate in the more confined atmosphere of buildings. Radon represents slightly more than one third of the average radiation exposure of people in France, i.e. 65 Bq/m^3 [12].

However, exposure levels are extremely varied. Thus there are areas where the activity rates in terms of volume are particularly high (for example, in France, the Massif Armoricain, the Massif Central and Corsica). France, like Switzerland, Germany and Spain has an average rate three times higher than that of Holland or the United Kingdom, but half that of Finland or Sweden.

Radon is associated with a risk of lung cancer. It is estimated that a year spent in a house at 200 Bq/m^3 leads to a 2.5 10^{-4} probability of death due to lung cancer. Therefore it is recommended to envisage measures to be taken in existing housing above 400 Bq/m^3 and to avoid a rate of more than 200 Bq/m^3 in future housing.

An extrapolation on the basis of a sample of more than 10,000 measurements taken in France in 1997 showed that around 300,000 homes exceed 400 Bq/m^3, and action taken for these homes would have an effect on around 20% of the general public risk.

3. How can we assess and manage the risks?

3.1 Many uncertainties, but a particularly favourable environment

Considering the numerous uncertainties highlighted above, it can be seen that buildings offer a particularly favourable context for the emergence of public health crises. Note must be taken of the following elements:

- Most risk factors are not perceptible (pathogenic micro-organisms, cancerigenic or toxic substances, ionising or electromagnetic radiation, radioactive substances, etc.).
- The exposure to contaminants in the air is omnipresent and generally involuntary.
- The effects on health are still uncertain whereas they are clearly not generally accepted by the population since buildings are considered as protective places. The levels of requirements, which in fact correspond to the search for the "zero risk", are thus much higher here than in any other field (such as for instance transport). Moreover the risks appear related to technologies and the populations at risk are especially children and old people. To the issue of community risk, it should therefore be added the issue of individual risk.
- Lastly, scientific and technical data, which is often very complex, limits communication between experts and the public on the risks involved.

Faced with this situation of uncertainty and complexity, methods for assessing and managing the risks have been developed.

3.2 Risk assessment

Risk assessment is a method for summing up and analysing available information concerning the toxic properties of a substance or an agent [13]. It is based on four elementary stages: identification of the danger, determination of the relation between the dose and the effect, estimation of the exposure of the populations, and characterisation of the risk.

3.2.1 Identification of the danger

This is mainly a qualitative stage that aims, according the available scientific data, to draw up the list of dangers associated with a chosen environmental agent and to give an indication of the plausibility of each of them.

3.2.2 Determination of the dose-effect relation

In this stage, the risk is determined for a given level of exposure to a toxic substance present in the environment. This assessment is based on relatively high levels of exposure, obtained in animal experiments in a laboratory or, for exemple, during high exposures of workers in their working environment. Then the probable effect is estimated by extrapolation, for the same population, at very low levels of exposure for which no data is available. Naturally, this must also take into account the differences between acute effects that occur after a short time due to high dose rates, and the chronic effects resulting from prolonged or repeated exposure at very low dose rates. Moreover it must be raised the problem of the type of extrapolation to apply: linear or threshold effect extrapolation? At last how to take account of accumulation effects which must not be neglected in the case of some contaminants (for example asbestos fibers)? All the uncertainties related to this approach imply that, in the end, a wider basis of investigation must be developed.

3.2.3 Estimation of the exposure

This stage concerns the identification of the populations potentially exposed to an agent, by relevant groups of age and sex. A very dangerous product for which the probability of exposure is zero does not pose a public health problem. On the other hand, a widespread factor - even if it is relatively harmless - of a frequent illness can be responsible for a large number of cases of this illness.

The identification of sources of pollution (building materials, ventilation system, presence of allergens, etc.), of the concentration of pollutants emitted, their frequencies, their stages of transition (air, water, food) and their level of impact on the target organisms are therefore key elements for the assessment of the exposure.

The exposure is estimated on the basis of various information, from measurements to mathematical modelling.

3.2.4 Characterisation of the risk

All the results of the above stages must then be to characterise the risk and provide elements for interpreting the scale of the risks in question. Although, in practice, the risk is often only characterised by a probability, the analysis of the risk implies many other factors that are necessary for management of priorities.

3.3 Management of priorities

To guide public health measures, there is a standard formal framework for determining the priority problems. The importance of a health problem is judged on the basis of epidemiological indicators such as the incidence and prevalence, the relative risk and attributable risk [14].

In general, two other parameters are considered to define priorities: the social perception of the problem and the existence of effective solutions.

The application of this framework to the sector of health risks related to the environment in general, and to the indoor environment of buildings in particular, raises many questions due to the complexity of the relationship between the environment and health.

People spend a large part of their time inside buildings. Therefore, as we have seen, the factors of exposure that are responsible for low risks on the individual level can nevertheless produce considerable risks in terms of public health, because of the size of the population exposed and the period of exposure. Characterisation of such exposure is complicated by the large number of sources of pollution within buildings and the wide temporal and spatial variations of contaminants present in housing.

Due to the existing scientific uncertainties, the incompleteness of available information and the structural weakness of the buildings-public health relation, it is not possible to reach a clear definition of priorities incorporating the protection of the occupants' health. In this situation, the possible recommendations must be considered in strategic more than operational terms.

For example, the objectives to be given priority in this context would be as follows:

- To increase awareness of all decision-makers by developing public research programmes, by providing information on exposures and by training and education.
- To deal with the most visible problems that can cause crises, for example, by establishing criteria for authorising the sale of new materials and products, launching maintenance programmes for ventilation systems, specific actions to be taken in sensitive places such as day nurseries, schools and hospitals.
- To introduce into the assessment procedures for innovative products (such as the procedure "Avis Technique" in France) some items which will enable a health risk assessment.
- To develop a policy of seals of approval with appropriate economic incentives to encourage the application of technological improvements that decrease risks in new buildings.
- In particular, it appears important to create places of exchange where building trade professionals, users and public health professionals can learn to work together to develop procedures for monitoring and alert procedures, capacities for informing the public and the players concerned, and also recommendations to enable public powers to act according to needs and constraints.
- To ensure, through an appropriate status, a total independence of the scientific expertise in the health domain.

4. Conclusion

The service life of a building is generally several decades (or even several hundred years). Recent cases of public health crises related to buildings, such as the asbestos crisis, show that it is very difficult to take action when sources of contamination in place in buildings become unacceptable due to both improved knowledge and changing requirements. Therefore it is very desirable to monitor potential sources of contamination at the earliest stages of the building process. This concerns product specifications and also construction systems and techniques in general, including maintenance and servicing.

The relationship between health and the quality of atmospheres inside buildings is a very wide-ranging and complex subject. It covers several areas of expertise, in the medical world and in building. Doctors, engineers and technicians must work more together in closer coordination. Their complementarity is more indispensable today, because knowledge has progressed in both medical and technical fields. However, many scientific uncertainties remain, which can only be gradually resolved by increasing research in all the fields concerned.

Glazing analysis in a cristal palace

J. Gallostra, M. Casals, M. Etxeberria
Department of Construction Engineering, Universitat Politecnica de Catalunya, Terrassa, Spain

Abstract
The aim of this paper is to demonstrate several conflictive aspects in the application of the sustainable concepts in the air-conditioning systems depending on the different geographic and climatic characteristics,

The showed study is corresponding to a Crystal Palace situated in Madrid (Spain), and the paper explain the different alternatives of actuation in the design of an air-conditioning system from a traditional point of view and from a sustainable concept's vision.

This big building is completelly built of glass, and the solar irradiation gains provoke than the indoor environment would be extremelly inadequate to human requirements, because the indoor temperature goes beyond the 60ºC.

We have realized the thermal modelization of the building, during single days and during short periods in summer and winter. The most interesting aspects appear in central summer days.

After this study and discussion of the results, the alternatives wich only comprise the installation of indoor air-conditioning systems is not enough to assure the appropriate indoor environment, including the use of radiant floor and a system to introduce fresh air inside the building.

It seems clearly that the most convenient alternative is changing the external glass although this solution neither is excellent.

One conclusion is that in hot countries is not enough the indoor air-conditioning systems to adequate the indoor environment of glazing buildings exposed to high direct solar radiation.

The unique sustainable solution must be to provide external elements to minimize the solar influence into the indoor-environment.

The final conclusion is that sustainable aspects should be defined in according to the different geographic regions, and the scientific and technical background of this question mustn't be done without consider the different aspects and different points of view depending on the origin and experience of the appraiser.

Keywords: geographic aspects in sustainability, solar radiation, sustainable indoor environment, use of existing buildings

1 Introduction

The aim of this paper is to demonstrate several conflictive aspects in the application of the sustainable concepts.

The first one is the different needs and implications as a result of the different building's performance according to the climatic characteristics depending on where is situated the building.

We try to demonstrate that relations between sustainable development and indoor environment, besides difficult are different depending on the particular country problems.

Finally, we try to demonstrate the difficulties to develop a common science background in this area.

The building case study is placed in the city of Madrid, on the centre on Iberian Peninsula. The building is situated in the *Parque del Retiro,* beside to the Buen Retiro Palace, royal residence of Felipe IV in the XVII century.

The Crystal Palace was built on 1887, and originally this building was a greenhouse to cultivate tropical plants.

In the last years this beautiful Crystal Palace was hardly used and the building was on full decline.

Recently the City Council of Madrid worked on a big plan to promote the reutilisation of historical existing buildings [1]. Inside this plan and with the aim to increase the use of the Retiro's Park facilities, they decided to adapt the Crystal Palace to a multifunctional space, dedicated to host cultural events like art expositions, editorial presentations or inaugural conference events, according to objectives of the initial plan.

The Spanish Ministry of Education and Culture ordered to different professional consultants the realisation of several parts of the reconstruction project.

This paper is based on the study and discussion of the air conditioning implications had in the reconstruction project of this building.

2 Environment conditions

2.1 Building characteristics

This crystal palace comprise only one big space (see Figure 1). The maximum height are the 25,25 meters of the dome. The lowest part of the building has 6,25 meters high.

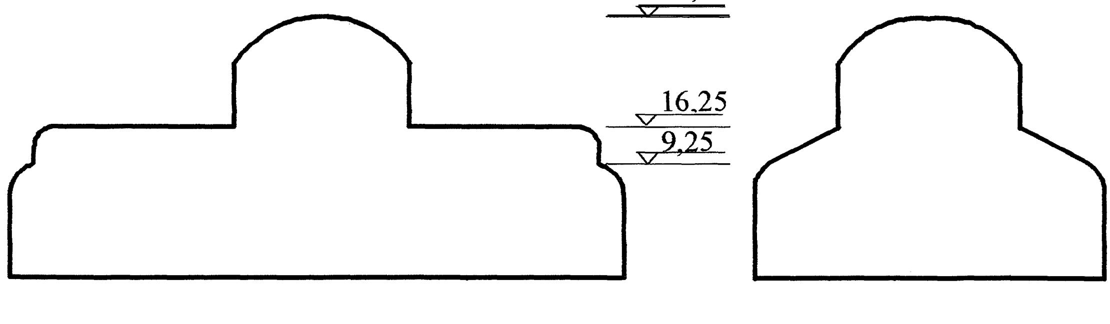

Figure 1. Schematic draft of the building (elevation and cross section)

The surface plant of the building is $1200m^2$. So, the total volume is approximately $17.000m^3$.

The complete building skin (façades and roofing) is made of simple crystal with a conductance of 166 W/m^2ºC and solar transmitance of 0.78 built-in over the original steel structure.

2.2 Regional climatic aspects

Madrid is placed on 40.48 Northern latitude and 595 meters over the sea level.

In summer the climatic conditions [2] are: a dry design temperature of 35.5ºC, and this temperature is overcome on 1% total times. The most probabilistic exterior humid temperature is around 21ºC.

In winter the dry design temperature is -4.2ºC, and the 1% of total times this value are overcome. The relative humidity is 95% and the prevailing wind is in the northern direction with a medium speed of 4.4 m/s.

2.3 Desired indoor climatic conditions.

Due to the Spanish regulations [3, 4], the indoor design climatic conditions have been fixed in 25ºC on summer. So, it's necessary to introduce corrective elements to provide an appropriate indoor environment in order to develop correctly the various possible events inside the building.

3 Analysis Methodology

In order to simulate the thermal ambient behaviour of the building we have used the program TAS.

The used methodology consists on dividing the total volume of the building in horizontal volumes. This division is shown in the Figure 2. Obviously, and checking the results, we didn't want to climate the complete volume of the building.

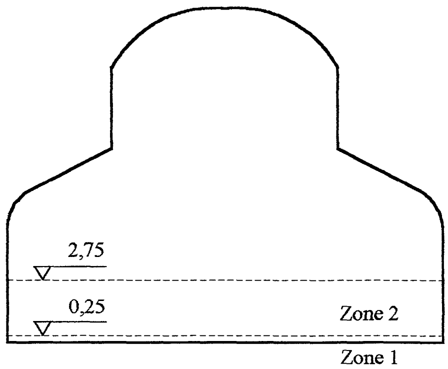

Figure 2. Schematic section draft of the building with mean zones of the model

We want to assure that the indoor environmental conditions of the 2nd zone (occupied zone) fullfil with the regulations and provide a correct indoor environmental conditions.

The zone 1 (radiant floor) is also important for the study. The 3rd zone is outside the possibly occupied zone (more than 2,5 meters of height).

The program calculate the temperatures distribution, the air movement, the needs of air impulsion taking in account the internal heat generations, the solar radiation aportations and the gains and loses by conduction in the different parts of the building [5].

Furthermore it is possible to define a combination of different systems in order to adapt the indoor environment of the building with this methodology and we are calculating different alternatives to air-conditioning the building.

In addition, this methodology response against a focused conditions fixed by a weather file where have been included the different weather magnitudes for all days of the year.

4 Discussion

4.1 Actual state

The first simulation was developed for a warm summer day (for instance August 7th) on the building in this actual conditions. The results of the simulation were that the temperature in top of 1st zone (floor) was 60.6ºC and the resultant temperature in 2nd zone was 62.5ºC.

When the simulation was done in dynamic conditions (during a period of five days before august 7th) the results were that the floor temperature was 64.9ºC and the indoor temperature was 65.6ºC. It seems clear that it is impossible to develop some human activity inside this building with these conditions.

4.2 Adding an air-conditioning system

The adopted solution was to provide an air-conditioning system formed by a radiant floor to regulate the floor temperature and adding cold air impulsion to compensate the insufficiency of this first system [6].

The floor radiant power necessary to assure than the floor will be at 18ºC in the central hours of the day is aproximatelly 375kW (over 300W/m^2).

For an usual value of aprox 36 W/m^2, the total power we want to obtain is 42.4 kW. With this power the floor temperature at central hours of the day is 25ºC.

The temperature in the occupied zone with this second case arrive to 34.4ºC (see Figure 3) at midday hours of the day, including an air impulsion of 35kg/s and 15ºC. If the air impulsion grow up, the temperature decreases slowly. For instance increasing the impulsion from 17 kg/s to 35kg/s the temperature decrease 1.5ºC.

With these conditions the required power plant had a power higher than 300 Kw and furthermore, it response is clearly insufficient.

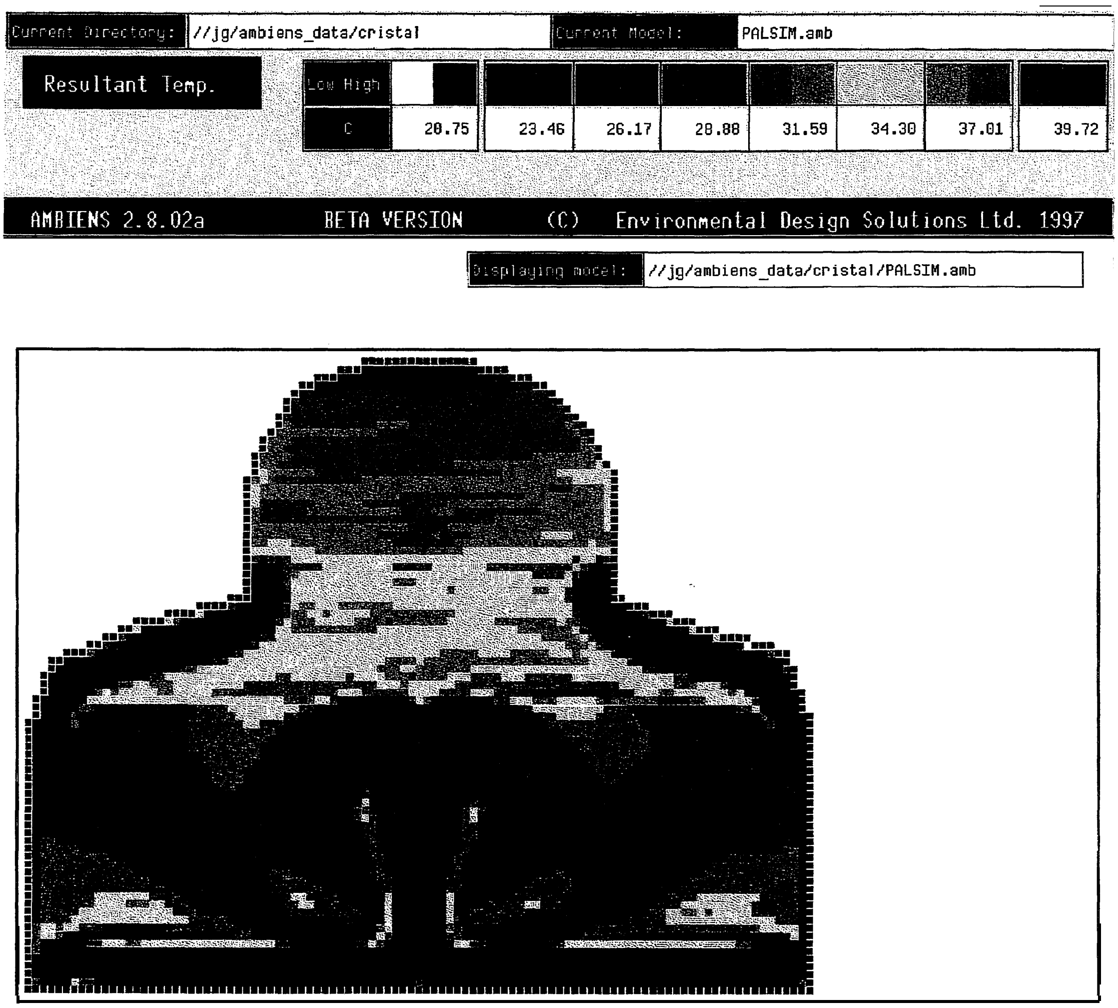

Figure 3. Indoor environment simulation with air-conditioning system.

With this case it is clearly demonstrate that only with air-conditiong system is impossible to air-conditioning this building.

4.3 Adding an air-conditioning system and changing the glass in the external skin
We decided that the solution should be to change the physical conditions of the building. So, we choose a new glass for the windows and the roof. The new glass has a solar transmitance of 0,37 and a conductance of $146W/m^{2}$°C. We can see the excellent behaviour of the new glass in front of the solar radiation.

With this new glass and in comparison with the last study we could observe that in this case the midday resultant temperature in the occupied zone is around 30°C (see Figure 4) with an air impulsion of 17kg/s and a radiant floor of 42,4 kW.

In this case and for these conditions the necessary cold production plant should have a power of 107 kW.

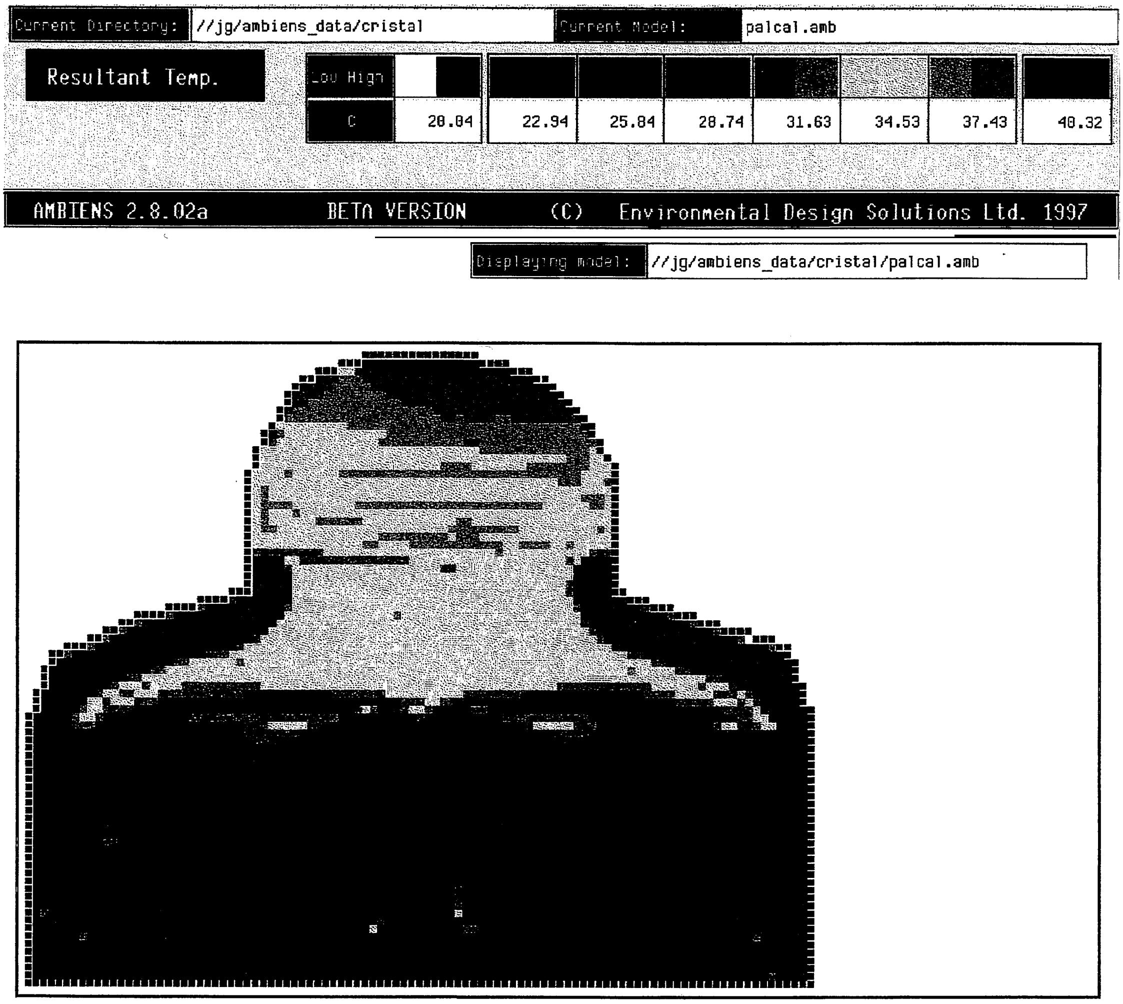

Figure 4. Indoor-environment simulation with air-conditioning system and new external glass

4.4 A traditional discussion versus sustainable discussion

From a traditional point of view we would have done a comparison between the cost of installation of the two options, adding the cost of consumption associate each solution and the cost of changing the glass. With all these costs and prices, and depending on the rate of return in years, the property would have decided.

From this point of view, the price of the glass would be recovered in aproximatelly three years.

From a sustainable point of view, we must to add the following aspects to this discussion:

- additional costs of production the elements (glass and air-conditioning production plants).
- cost of space (in the basement floor the space is strong restricted, and depending on the utilization of an air-conditioning plant or another plant would be important for the space saved).
- evaluation of the real needs to arrange the building, and if this arrangement is strictly necessari, may be is not necessary the building performance at warmed-up midday hours on summer.

5 Conclusions

In hot countries, the solution to avoid solar irradiation in buildings is provide an adequate sunshades in facades or externally to the buildings (in this case, we could use the situation in a park to provide a vegetal sunshades). Whichever other indoor solution don't response effectivelly to the user requirements and obviously, so it is not sustainable.

The most important conclusion that we can observe is the different implication of the different aspects in the evaluation of an air-conditioning system depending on the point of view from the appraiser.

If we want to introduce sustainable aspects in whatever evaluation, we should to consider a great range of aspects (from the use of spaces to the energy consumption in the production of systems).

Sometimes, depending on the particular problems of the country or the region, is difficult to use defined sustainable points of view. So, in cold countries the solar irradiation could be used positively to save energy in efficient energy buildings (lighting and heating), but in hot countries (for instance mediterranean countries) the solar irradiation could be the biggest problem.

The conclusion to this question is that sustainable aspects should be defined in according to the different regions, and the scientific and technical background of this question mustn't be done without consider the different aspects and different points of view depending on the origin of the appraiser.

6 Acknowledgements

We want to thank to Grupo JG&Asociados Consultant Engineers, and the Spanish Ministry of Education and Culture for their helpful in the supply of information to prepare this paper.

Guidelines for indoor air quality in schools: Creation of healthy indoor environment

I. Sävenstrand Rådö, Eva Falck, Marie Hult, National Institute of Public Health, Sweden
J. V. Bakke, Norwegian Labour Inspectorate, Gjøvik, Norway

Abstract

This article describes a model for the way the authorities can disseminate research results relating to the indoor environment and health, so that they will be applied in practice in the form of advice and aids for the different players who exert an influence on the design, renovation and management of school buildings - with the aim of improving the indoor environment for children and young people.

Allergies are on the increase in the whole western world. According to "European white paper - allergic diseases as a public health issue", about 35% of the population of Europe is affected. In Sweden, one in three of all adults and four out of ten school children have some form of allergy. For young adults the figure is 50%. (Max Kjellman, Allergy Conference 96). The increase observed over the past decades shows no signs of abating.

There are a lot of indications that the indoor environment is a contributory factor in this worrying development. Several studies have shown the the indoor environment of children and young people in schools and day nurseries is the worst. In such environments there is an increased frequency of sick building symptoms, and many develop a hypersensitivity which becomes permanent. One important stage in bringing about an improvement in health that will endure in the long term is to prevent allergy and sick building symptoms in school by exercising strict control over the indoor environment.

Ever since the middle of the 1970s a large number of schools in Sweden have had to be renovated and prematurely demolished because the building had made children and staff ill. Nor is it sustainable to construct buildings that are not fit for their purpose.

The change to a society that is sustainable in the long term must comprise both indoor environment/health, resource economy and provision for recycling. Health issues in the indoor environment must be made a self evident part of the environmental adaptation which is now taking place in the construction sector.

In 1995, the National Institute of Public Health carried out a broad based information campaign, called Allergy Year 95. In connection with this, the Institute developed a knowledge base regarding the relationship between indoor environment and health, and disseminated research results and aids based on these which had the aim of facilitating the planning of healthy school buildings.

Two handbooks were published, "Methods for healthy renovation and management of schools", and "Methods of surveying school buildings with indoor climate problems, and remedial measures". These handbooks were presented to decision makers and school staff through a large number of local conferences held in collaboration between several authorities. They also constituted a common framework for international cooperation between researchers and authorities within ISIAQ. Within the framework of ISIAQ, a report is to be drawn up by the year 2000. The handbooks - with guidelines geared to different aspects - are intended for a number of different players who are involved in the physical environment of schools. They refer to three different situations in which it is particularly important to pay attention to the indoor climate: 1. The operational stage, 2. In conjunction with renovation (also mainly applicable for new building), 3. If climatic problems occur in a school.

Key **words:** Schools, indoor environment, allergy, guidelines, renovation, management, maintenance.

1. Introduction

1.1 Allergy - the public health issue of our times

Allergies are on the increase in the whole western world. According to "European white paper - allergic diseases as a public health issue", about 35% of the population of Europe is affected. In Sweden, one in three of all adults and four out of ten school children have some form of allergy. For young adults the figure is 50%. (Max Kjellman, Allergy Conference 96). The increase observed over the past decades shows no signs of abating. In order to counteract this development, preventive measures must be taken - especially in the environments of children and young people.

1.2 Knowledge and methods of prevention

There is a relationship between indoor environment and health. Allergic persons react strongly to sick building environments. Many develop hypersensitivity which becomes permanent.

In Sweden and the other Nordic countries, knowledge and methods of dealing with indoor environment problems in schools have been developed over several decades. In response to a government mandate in 1994, the National Institute of Public Health has produced information material on how a healthy indoor environment in conjunction with the renovation of school premises can be created and maintained. The material also contains advice on what to do when problems occur in the indoor environment. The information in both pulications has been disseminated to commissioning departments in the municipalities via conferences and seminars.

In the autumn of 1995, the Board of ISIAQ commissioned Inger Savenstrand Rådö, National Instituite of Public Health, Sweden, to form a working group and draw up "Guidelines for good indoor air quality in schools". An initial workshop was held in Nagoya in 1996 at which several countries expressed an interest in participating in the work. It is expected that the final report on this work will be published in the year 2000. The main purpose of the group's work is to describe measures for the creation of healthy school environments. At the seminar Healthy Building in Washington in September 1997, Inger Savenstrand Rådö presented methods for the creation of healthy buildings. The delegates agreed on the following statement: "Allergy and other hypersensitivities are the most common diseases among children and youngsters in the western industrialised world. It is therefore necessary to look upon the environment in schools from *an allergy point of* view to prevent pupils being sensitised (primary prevention) and to minimise the problems for pupils already affected (sensitised) (secondary and tertiary prevention) . . .."

13 The "Swedish model" - work for sustainable improvement in health

Through the establishment in 1992 of a new authority, the National Institute of Public Health, the task of which is to work for the improvement of public health and the prevention of adverse health effects, the allergy issue was given prominence and preventive work could begin. Knowledge at the scientific level can be translated into tools of practical utility and transferred to important target groups. Allergy issues were highlighted in a campaign year in 1995. The significance of the indoor environment for health was one of the areas. The cost of producing information material, arranging conferences and seminars was borne by the Institute.

A group of authorities was formed for collaboration on indoor environment issues. 14 authorities and organisations contribute with their spheres of responsibility regarding the indoor environment. The group includes the National Board of Occupational Safety and Health, the National Board of Housing, Building and Planning, the National Board of Health and Welfare, the National Association of Local Authorities, the Swedish Council for Building Research, etc. The National Institute of Public Health holds the chair in the group. The group is now making plans, together with industries and organisations, for a joint demonstration of indoor environment issues over a whole year - Indoor Environment Year 1999.

The Swedish Government is aware of the problems concerning poor school environments. Special funds have been made available for the upgrading and renovation of indoor environments in schools.

Many Swedish municipalites have passed political resolutions that an endeavour is to be made to create allergy-free environments. One in three municipalities have interdisciplinary groups, 'allergy committees', which have the aim of preventing allergies and making life easier for allergic persons. These groups provide the impetus and provoke interest in environmental issues, so that initiatives are taken to improve matters. The interdisciplinary composition of these working groups is an important factor in their work for healthy indoor environments.

The environmental debate in Sweden has long concentrated on utilisation of natural resources and less on the effect of air pollution on human health and the quality of life. Nor have indoor issues received enough attention in relation to the scope of the problem: on average, we spend 90% of our time indoors. In the work on Agenda 2 1, which is taking place in all municipalities in Sweden, health aspects should be given prominence as an expression of a holistic approach to human beings. Material for this has been submitted in the report of the government Commission on Environmental Health (SOU 1996: 124).

Ecological construction forms part of the change in Sweden towards a society that is sustainable in the long term, with provision for recycling and more effective use of energy as its goals. The structural solutions vary, and it is assumed that the health advantages for those who live and work in these buildings are a natural consequence of interest in the environment. Experiences and descriptions of health effects have not yet been compiled. Health impact assessments in conjunction with ecological construction should therefore be recommended.

2. Characteristics of healthy schools

As part of the work within the ISIAQ group on school environments, there have been discussions on what it is that characterises a school building with a good indoor climate. Characterisation of a healthy school building is a good basis in setting up goals and specifying requirements for the indoor climate. A client who does not define his wishes regarding the indoor climate cannot expect to have these wishes satisfied. Specific performance requirements for a good indoor climate in schools may look different depending on the aspirations of the client, but they also vary from country to country. The starting points are different owing to differences in occupancy rates, building traditions, outdoor climate etc. We have therefore decided in this context to describe the general characteristics of a healthy school in a Nordic climate.

2 1 Characteristics of healthy environments in schools

The environment in school should not initiate or provoke any diseases or accidents. Allergy and other hypersensitivities are the most common diseases among children and young people in the western industrialised world. It is therefore necessary to look upon the environment in schools from an allergy point of view to prevent pupils being sensitised ('primary prevention) and to minimise problems for pupils who are already affected (sensitised). (Secondary and tertiary prevention).

One basic function of a school is to provide stimulating and productive educational environments for the learning process[1].At least three different pedagogic settings which are difficult to combine in the same room may require different environmental solutions regarding acoustics, lighting, etc. These are the **classroom** (for teaching, lectures, teacher-class dialogue), the **silent room** (for individual concentration, e.g. a library) and the **group room.** A separate place to eat may also be needed.

2.2 Requirements

1. **Tobacco** (Environmental tobacco smoke, ETS). Children have the right to ETS-free environments. Exposure to ETS should be minimised. Tobacco smoking should be prohibited

in schools - both indoors and outdoors! (Already implemented in Sweden, Finland, Norway and other countries). One problem is how to define non-exposure level.

Cleaning to prevent accumulation of dust and other pollutants. The educational context in school must be taken into consideration. The requirements depend on needs defined by occupancy rates and activities and must comprise all surfaces exposed to indoor air. They include regular cleaning, periodical thorough cleaning and washing of fabrics and curtains. Furnishings and surfaces should make it possible for cleaning of advanced standard to be carried out. Cleaning should be performed using environmentally friendly methods and chemicals. The Clean Building Philosophy must be incorporated into the construction process[2].

Maintenance has to be adequate according to the needs of the specific building.

Carpets are a potential source of allergy. In order to minimise exposure to allergens and bioaerosols, fitted carpets should not be used in classrooms and other premises where children are present. Acoustic problems can be solved without creating new sources of pollution (MMMF, rockwool and fibreglass dust).

Allergens - pets, furry animals. Animals should not be allowed to enter schools. Special precautions must be taken if a guide dog is needed.

In order to avoid high levels of allergens being transported in clothes from home and outdoor environments, there may be a need for routines for cleaning clothes, ventilated wardrobes, special school uniforms, use of indoor shoes, etc.

Ventilation with fresh air is needed for good indoor air quality, to avoid moisture damage and to reduce infections, allergy problems and SBS symptoms. Investigations are needed concerning the influence of ventilation on the transmission of colds and flu.

Methods

l Methods for the operation and maintenance of schools

ice addressed to the different players who influence the operation and maintenance of heating, ilation etc installations in schools was included in the material produced during Allergy Year This advice is also geared to different stages in the life cycle of a school. It is often faults which :asy to put right that cause an unnecessary deterioration in the indoor climate. Well functioning ation is not only a health issue but also lays the foundations for effective energy use.

ı for operation and maintenance - advice for designers and clients

:ther operation and maintenance will function well in a long term perspective is decided as early uring the planning of new construction or renovation. Important decisions are made in the early es. Who can or wants to look after a building which has constricted service rooms and/or cult transport routes, or has no sampling points for check measurements on heating and ilation?

fly, the advice developed in the handbook is as follows:

Put operational and maintenance issues on the agenda already at the programme stage and call operational staff to planning meetings.

Budget for easy to understand operational and maintenance instructions which are drawn up for the building in question.

Appoint the person responsible for operation and maintenance at an early stage.

Make provision for continuous inspection. During the procurement process, refer to prepared models of operational and maintenance instructions.
Be well informed about codes and applicable legislation.

Allow time for the commissioning of the building - advice for clients, contractors and designers

Faults or shortcomings always occur during the design and construction stages. These may often be difficult to detect and may give rise to high operating costs. It is therefore important to make proper provision for the commissioning of the building, i.e. to test all systems and adjust these until they work as intended and the faults have been put right.

Briefly, the advice developed in the handbook is as follows:

Budget for commissioning.
The person in charge of design should be responsibe for commissioning during the entire construction process.
Ensure that commissioning is included in the programme documents.
Draw up a plan for commissioning. Make provision for control functions.
Draw up clear descriptions of different system solutions and how they must be tested.
Make specially careful observations of climate, technology and energy use during the first two years. Plan for follow-up questionnaires and measurements.

How to carry out operation and maintenance for a good indoor environment - advice for operational staff

Briefly, the advice developed in the handbook is as follows:

Make sure that complete, easy to understand operating and maintenance instructions, drawn up for the building in question, are available. Test them and ask questions.
Check the climate in the school regularly in conjunction with the annual safety inspection. Use questionnaires and measurements. Talk to the users.
Set up clear signs in the plant room for the different components of the heating and ventilation installation. Also put up signs in the premises to show when the ventilation was last checked and how many people the room is intended for.

2.3.2 Methods for healthy renovation of schools

Advice on how indoor climate issues can be monitored when a school is renovated has been compiled in a special programme. This was produced by the National Institute of Public Health for Allergy Year 95 in cooperation between indoor environment researchers, physicians and building practitioners. The programme has since been subjected to broader scrutiny by professionals in different areas. Much in this programme is also applicable for new construction and for buildings other than schools. Briefly, the six fundamental methodological steps recommended and developed in the programme are as follows:

1. *Form a renovation group of broad competence.*
   Instruct the group to collect the most recent research findings concerning the indoor environment.
2. *Draw up a situation report on the existing indoor environment in the school.*
   Using a questionnaire, investigate air quality, thermal environment, acoustics and lighting. One aid that is available is a school questionnaire on indoor environment and health. Make technical measurements of moisture states and air flow rates if the questionnaire indicates defects. What is worth preserving and what needs to be improved?
3. *Formulate goals for the indoor environment.*

Do this in the form of performance requirements, i.e. in terms that can be checked and in terms of **requirements concerning the properties of the building -** not in terms of the technical solutions. An aid gives examples of how checkable goals can be formulated.

4. *Apply quality assurance.*
   Specify performance requirements for building materials, system solutions, structures, workmanship and working methods on the site (dry and clean site, materials control, etc). The performance requirements must be commensurate with the goals set up in Item 3. An aid gives examples of what a checklist for quality assurance may look like.
5. *Make observations of indoor climate in the finished building.*
   Check the attainment of the goals using a questionnaire. Allow time for commissioning and experience feedback.
6. *Make observations of indoor climate during school hours.*
   This can be done using a standard questionnaire. In order to pay special attention to the situation of allergic persons, an allergy inspection can be made. This is described in detail at the end of this article as an example of the aids which the programme contains. Finally, the importance of careful operation and maintenance is emphasised - one of the ways of ensuring this is to train staff.

2.3.3 Methods of surveying school buildings with indoor climate problems, and remedial remedial measures

Advice on how school buildings can be surveyed in stages and how problems can be put right were summarised in an easy to read book published by the National Institute of Public Health and the Association of Swedish Local Authorities in 1996. The book came into being as a result of interviews by a journalist with a number of researchers, physicians and people responsible for real estate in some municipalities with experience of sick buildings.

This method book is also divided into six main stages for remedial measures. Briefly, the six methodological stages recommended and developed in the book are as follows:

1. *Make simple checks - lis ten to those who work in the premises.*
   Take remedial measures if the causes can be established. Follow up the effects of these measures. If this is not enough,
2. *Make an initial inspection of the building.*
   As the basis for the inspection, the building owner provides documents which describe how the building is intended to function. Any deviations are to be noted during the inspection. Take remedial measures if the causes can be established. Follow up the effects of these measures. If this is not enough,
3. *Make a standardised questionnaire survey or interview the users.*
   Collate the results and analyse which environmental and health factors annoy the users. Take remedial measures if the causes can be established. Follow up the effects of these measures. If this is not enough,
4. *Continue investigations in the building.*
   Check the structure and the building services (moisture, odours, heating, acoustics, lighting), the use of the premises, cleaning, "environmental culprits" and individual factors Take remedial measures if the causes can be established. Follow up the effects of these measures. If this is not enough,
5. *Make in-depth measurements depending on how well the causes have been located.*
   Air flow rates, chemical reactions/alkalinity, microorganisms, thermal environment, acoustics and lighting. Take remedial measures if the causes can be established. Follow up the effects of these measures. If this is not enough,
6. *Medically examine the users and make targeted measurements.*

Great attention is paid in the book to the interaction between the different players during the various stages. The situations which arise when the health of pupils and staff in a school is at stake are very sensitive. It is emphasised that the building owner should listen to the views of the users and should work systematically and in stages, with each stage firmly tied to the previous ones.

2.4 Examples of aids - Allergy Inspection

The checklist for the allergy inspection is a working tool for the identification of allergy risks in the indoor environment.

The allergy inspection is a safety inspection with allergy as its theme, and should be made by those who normally deal with environmental issues in the school. Those taking part in the allergy inspection should be, in the first place, the headmaster, safety officer, pupils' safety representative/parents' representative and school nurse. The person responsible for the building should attend to issues concerning indoor climate and ventilation, the person responsible for meals to issues concerning food, and staff responsible for cleaning to issues concerning cleaning.

The completed checklist will then form the basis for a plan of action for remedial work. In most cases, some measures can be taken quickly at low cost, others require a longer tertn approach. It is important that 'attitude' issues such as those concerning smoking, furry animals and perfume should be kept under continual review and highlighted.

It is not necessary to be an expert in allergy issues to make an allergy inspection, it is a learning process. The checklist is an aid in quickly and easily obtaining an overview of where allergy risks are to be found and which factors in the environment or the activity should be put right. Examples of issues which are examined are:

Health issues
Indoor climate
Ventilation
smoking
Furry animals
Perfumes
Plants
Food
Facilities management

The checklist is a good aid to use in the annual safety inspection. It focuses on the indoor climate for allergic children and at the same time calls attention to a healthy environment for all children.

Abstract

The process of sorption of air contaminants and the subsequent desorption may have important consequences for the indoor air quality. For example, occasional release of consumer chemicals leads to momentarily high concentrations in the room air, which in turn results in a strong sorption on material surfaces. This paper treats the methodology and development of an experimental equipment for investigating how volatile organic compounds are sorbed on material surfaces. A mathematical model which incorporates mass transfer from bulk air to surface, surface adsorption, diffusion into the material and absorption is proposed. It is possible to evaluate four physical parameters when adapting the model to measurement data. The paper presents sorption experiments of toluene on three materials; stainless steel, wood particle board and gypsum board. The result shows that toluene is sorbed to a higher extent on a gypsum board than on a wood particle board. Gypsum board and wood particle board are permeable for toluene, while stainless steel is not. The proposed measurement technique seems to be applicable for determination of such material parameters which are necessary for predicting the indoor air quality in a real environment.

1 Introduction

Due to indoor contamination sources of different kinds, the indoor air is as a rule more polluted than the ambient air. The sources of contaminants are broadly speaking all materials which we have indoors, building materials, fittings, furnishings, consumer products etc. Not least are we - the occupants, with all our activities - major contributors to the contamination. Cleaning, cooking, painting, gluing, using deodorants and perfumes and other body care products all have a negative effect. Lastly the biological metabolism itself makes contributions which should be eliminated.

The main purpose of ventilation is to remove contaminants from the indoor environment. The classical way is to treat ventilation as a dilution process. The level of air contamination is then modelled by a simple differential equation, which states that the amount of pollutant accumulated in the room air is the difference between what is supplied from the sources (the emission rate) and what is extracted along with the ventilation air.

However, over the past few years it has become obvious that other processes play an important part in the level of contamination. Specifically, all material surfaces in the room interact with the air contaminants in an exchange process. Such interactions may have a large impact on the human exposure to air contaminants. Occasional release of consumer chemicals leads to momentarily high concentrations in the room air, which in turn results in a strong "sorption" on material surfaces. Later, the sorbed compounds may slowly migrate back to the room air, yielding an extended exposure time. Repeated use of consumer chemicals can build up considerable depots of contaminants in indoor materials.

Only a small part of the compounds in indoor air comes from this secondary emission from such depots. The main part is generated directly from the primary sources. However, people often avoid exposure to much of the primary emissions by leaving the room for example. When painting, it is common to leave the room while waiting for the paint to dry. The odour is often a signal to avoid primary emission, - a factor which is normally not present during secondary emission, due to the relatively low concentration. As chemicals are often released repeatedly in the indoor environment, there will be a build up of compounds in the depots. This may cause the subsequent re-emission from depots to be greater than the emission from primary sources, such as building materials, which decays after some time in a new building.

It should be clearly stated that the depot effect is not the major contributor to the average levels of contaminants in indoor air, but it may be of significance due to prolonged low level exposure for humans.

In order to find the most effective ways of protecting people from adverse exposure to indoor contaminants, it is essential to be able to predict what happens when chemicals are brought inside. Knowledge of source emission rates and ventilation characteristics are essential for predicting indoor air quality, but to complete the picture, the adsorption and desorption characteristics of different contaminants on different materials must also be known.

The mathematical model of the processes should be formulated in terms of physical interpretable parameters, such as diffusion coefficients and equilibrium constants and it should be of general validity.

The aim of this work is to develop an experimental methodology, with which such material parameters, necessary to describe the sorption/desorption process, can be determined.

2 Mechanism of the sorption process and a simple mathematical model.

The sorption process of contaminants on a solid material can be looked upon as seriallv coupled sub-processes consisting of:

1. Diffusion from bulk air through the boundary layer near the surface
2. Surface adsorption
3. Diffusion into the material
4. Absorption in the interior of the material

For simplicity all processes are considered reversible so the re-emission follows the reverse process.

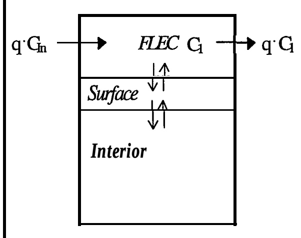

Figure 1. The sorption process.

Simple mathematical models can be set up for each of these sub-processes. Numerical solution of the system of simultaneous differential equations can be compared with experiments in order to determine the model parameters.

2.1 Governing equations

2.1.1 Diffusion through the boundary layer:
The mass transfer rate of the gaseous compound from the bulk air phase to the surface is described by a mass transfer coefficient k_g so that

$$J_1=Ak_g(c_a-c_s) \quad \textbf{(1)}$$

where c_a is the concentration in the air phase and c_s is the gas phase concentration of the compound at the surface interface.

2.1.2 Adsorption on the surface: This process is considered so fast that the gas phase concentration at the surface interface c_s is always equal to the gas phase concentration of the compound in equilibrium with the surface.

Thus, c_s is determined by the equilibrium constant, K_s, for the surface adsorbed compound.

$$K_s = \frac{c_s}{C_s} \quad \textbf{(2)}$$

where C_s is the concentration of adsorbed compound on the surface. This equation corresponds to a so called linear adsorption isotherm. The linear relation was demonstrated by Tichenor [1] in similar experiments.

2.1.3 Diffusion into the interior of the material.

This process is considered a pure diffusion process and is not normally covered in already existing models in ref. [1],[2]and [3]. The compound balance equation in one dimension for a porous media can be formulated as:

$$\frac{\partial C}{\partial t} = -\frac{\partial}{\partial x}(g) \quad \textbf{(3)}$$

where C is the total concentration of the compound inside the material, xis the distance from the surface and g is the compound flux caused by diffusion:

$$g = -D\frac{\partial c}{\partial x} \quad \textbf{(4)}$$

where D is the molecular diffusion coefficient and c is a fictitious gas phase concentration (or activity), in the material.

c_i is determined by the equilibrium constant, K_i , between the vapour and the total concentration of compound.

$$K_i = \frac{c_i}{C_i} \quad \textbf{(5)}$$

Equation 3 can now be written as;

$$\frac{\partial c}{\partial t} = D \cdot K_i \frac{\partial^2 c}{\partial x^2} \quad \textbf{(6)}$$

2.2 Adapting of the model

Assuming numerical values of the four parameters (k_g K_s D and K_i), the system of equations together with the boundary conditions can be numerically solved using a finite difference technique. Comparing the result with experiments allows the parameters to be adjusted to yield a best fit between the numerical solution and the experimental data. Figure 2 shows an example of such a fit.

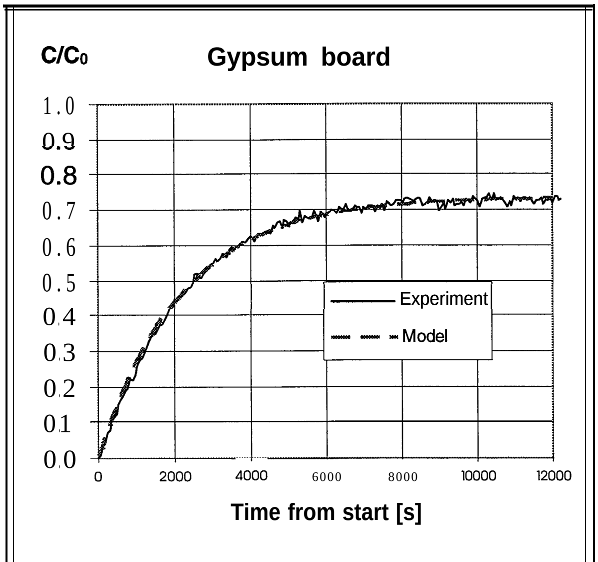

Figure 2. *Adaptation of model parameters to experimental data. c/c_0 (chamber outlet concentration / 'nlet concentration) versus time.*

The experiment was performed according to the procedure described in the experimental section of this paper. In essence a step change of the inlet concentration (from zero to c_0) of a contaminant in the air ventilating the space above a solid material is performed.

Figure 2 displays the experimental and modelled relative chamber concentration for gypsum board when subjected to 100 ml/min of dry air with an inlet toluene concentration of 10 mg/m^3.

3 Experimental study

This section describes the experimental methodology and equipment. The aim of the study is to further develop and test an experimental technique, with which the material parameters in a general adsorption model can be determined. The objective being to develop a convenient small scale technique, yielding sufficient data necessary for modelling behaviour in full scale reality.

3.1 Experimental method

In this pre-study we have focused on the adsorption process. Of course this is just one part of the depot phenomenon and in the near future the desorption process will also be evaluated. The methodology used in these experiments involves exposing a test material placed in a small climate chamber to a volatile organic compound (VOC). Toluene was chosen as a model compound in this case. By studying the concentration in the outlet as a function of time after a step change in the inlet concentration, it is possible to examine the adsorption/absorption properties.

3.2 Climate chamber

The FLEC (Field and Laboratory Emission Cell) was used in these experiments. The FLEC was originally designed for analysis of emissions of VOCs from building materials. The equipment mainly consists of a circular cover made of stainless steel, with an inner geometry which provides a uniform air velocity over the test sample [4]. It is placed on top of the test material, so that the test material forms the bottom of the apparatus. The enclosed volume is 35 cm^3 and the exposed area of the test specimen is 0.0177 m^2 , which gives a maximum loading factor of 506 m^2/m^3. The surface to volume loading factor of the FLEC is therefore nearly 300 times that of an ordinary room. Only one side of the material is exposed to the compound as in a real room.

3.3 Climate control

In order to provide a controlled temperature during the tests, the test specimen was supported from below by a 30 mm thick thermostated aluminium plate, through which thermostated water was circulated in a 5 mm wide channel in the form of a labyrinth. This equipment together with a hood of polystyrene (10 cm thick), insulating the FLEC, test material and the thermostated plate, were sufficient to control the temperature for the experiments.

3.4 Sealing method

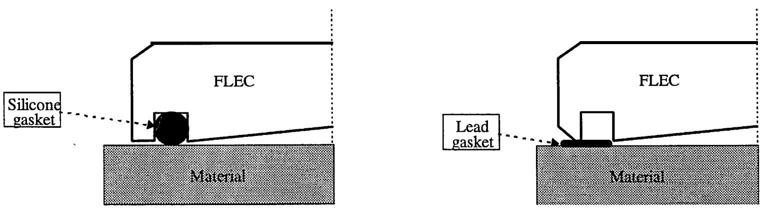

Figure *3. The outside perimeter of the FLEC with its original gasket which acts as a sink for toluene (left). Sharpened perimeter and new gasket (right). The sharpening leads to increased pressure on the lead gasket (for deformation).*

The sealing of the FLEC to the test material is of great importance in these experiments. Factors influenced by the type of seal are: air flow rate and air velocity as well as the adsorption and desorption rate. At the start of this project it was discovered that the original O-ring seal, made of silicone rubber, acted as a severe depot and leak for toluene vapour. For this reason a new seal was designed. Several attempts were made in order to fulfil the requirements of tightness, impermeability and non-sorbing characteristics towards toluene. The latest successful version is shown in figure 3 in which the FLEC was sharpened on the outside perimeter to provide enough pressure on the seal. The seal was manufactured from a lead foil (1.5 mm thick). The metal is impermeable to toluene and has negligible adsorption. Each experiment requires a new seal because of the deformation when the FLEC is fixed to the test material. The pressure for deformation was organised by six stainless steel clamps threaded into the aluminium plate.

3.5 Air generation

The compressed air system at the laboratory is of good quality, dry (RH< 5 %) and with low particulate content. However, to reduce the amount of VOCs originating from the compressor oil a gas-clean charcoal filter is used. The filter manages to keep the VOC-level below 1 ppm for one year. For safety reasons, if the internal dryer of the compressed air system should break down or malfunction, a gas-clean moisture filter is used. Both filters are of a type normally found in gas chromatography applications. Additionally, for protection of valves and the analysis equipment, a Nupro ”F series” particle filter is used which traps particles of diameters down to 0.5 microns.

3.6 Compound

Toluene was chosen as the model substance because it is a common contaminant in the air having consequences for health. The average concentrations of toluene in room air are 80 $\mu g/m^3$ and 5 $\mu g/m^3$ in ambient air [5]. It is a common solvent and is found for example in detergents, cleaning agents, glues and paints. Occurrence of toluene is of health concern because it can irritate the mucous membranes. Jorgensen [6] has reviewed results from four investigations of screenings of compounds in the indoor air of buildings (mainly dwellings) in Denmark, Italy, Germany and USA. This was done in order to choose relevant compounds for experiments similar to the present ones. Two compounds from 21 examined were chosen by her, a-pinen and toluene. Toluene was chosen because of its irritating effect and its occurrence rate.

3.7 Compound generation

Air with a fixed concentration of toluene was prepared by letting a constant flow of the purified air pass a constant source of toluene vapour. The source (fig. 4) consists of a container of aluminium in which a wick of fibre glass is placed. At the open end of the container a glass capillary tube is fixed to the container wall with a solvent free epoxy resin. The resin is not permeable to toluene. Before using the sources, liquid toluene is injected with a syringe through the capillary tube into the wick. Because of the fact that the vapour pressure is strongly dependent on temperature, the source is kept at a constant temperature of 20 °C. Toluene vapour is emitted at a constant rate controlled by diffusion through the capillary tube the dimensions of the glass tube (diameter and height) governing the emission rate. Calibration of the emission rate is performed by weighing the sources with an accurate balance. The emission rate of the sources used in these experiments is 50 ng/s.

3.8 Compound compartment

In the compound generator compartment the compound emitted from the source is mixed with air to the desired concentration. As for the FLEC it was important to minimise adsorption and eliminate leakage and diffusion out of the compartment. The generator compartment therefore only contains metal and consists of an U-shaped copper tube, equipped with brass fittings mounted with compressor couplings. The tracer sources are placed in the vertical part of the compartment near the air inlet. The compound compartment with its content is immersed in a water circulator which maintains a constant temperature of 20 °C.

3.9 Flow chart and flow control

The flow of air in the experiments is illustrated in a flow chart in figure 5. The compressed and filtered air is divided into two paths: for contaminated and clean air respectively. The former is contaminated in the compound compartment and distributed to a switch valve where it either flows into the FLEC or out into the lab (flush). Between the compound compartment and the switch valve there is an additional branch pipe were one part of the air is continuously bypassed for control measurement of the desired concentration. The clean air flows directly to a switch valve where it either enters the FLEC or travels out into the lab (flush). Adsorption experiments start by flushing the FLEC with clean air (switch valves are positioned so that clean air flows into the FLEC and contaminated air flows out into the lab, path A in figure 5). When the FLEC is to be exposed to the compound, the switch valves are positioned in the other direction so that contaminated air flows into the FLEC and clean air flows out into the lab. The air flow through the compound compartment and FLEC is controlled by precise stainless steel needle valves. Flow measurements are performed with a digital soap film flow meter which requires a negligible pressure drop. This is essential since there is a slight over-pressure in the FLEC and any increase of this may influence the air flow through it.

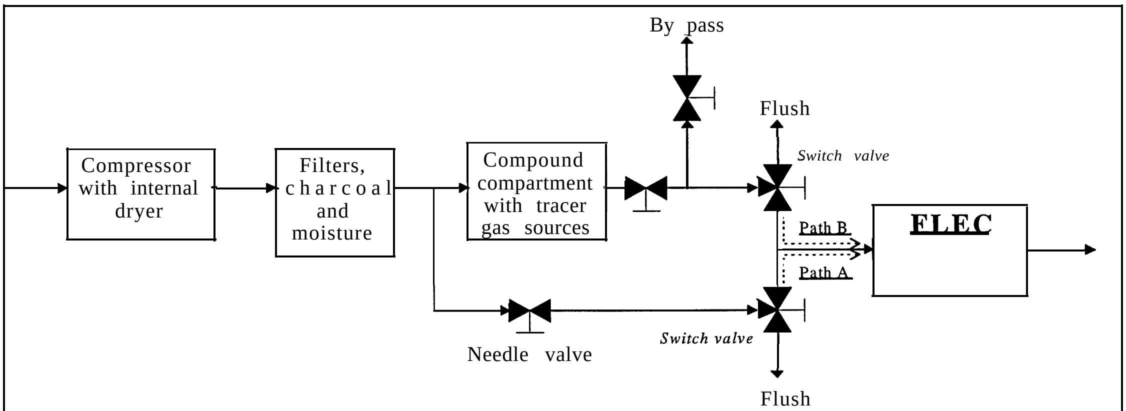

Figure *5. Flow chart of the experimental set-up. Before the step change in contaminant concentration the clean air flows through the FLEC (path A) and the contaminated air is flushed out into the lab. At the start of an adsorption experiment contaminated air is allowed to enter the FLEC (path B). When a steady state concentration is established in the FLEC outlet, path B is changed for path A. Switching between clean and contaminated air is managed by simultaneous operation of the two switch valves*

3.10 Concentration measurement method

The concentration of toluene in air was measured with a Balzers quadrupol mass spectrometer (MS). Other analysis techniques exist which could have been used: gas chromatography or IR-spectroscopy. The fast sampling interval and the presentation of data in real-time are the main advantages of MS. One disadvantage however is the poor detection limit, 0.2-0.5 ppm. A personal computer together with the software "QUADSTAR 421" from Balzers makes it easy to control the mass spectrometer and follow the concentration of the compound in real time.

3.11 Test material

The materials examined in this work were: gypsum board and wood particle board. The chosen building materials are often used in building construction. Additionally, a stainless steel plate was used for tests where the internal depots of the experimental apparatus were to be examined. The test materials had been stored for one to several years in the laboratory workshop (20 - 25 °C and RH = 30 -50 % approx.) before the experiments.

3.12 Experimental conditions

The stainless steel, gypsum board and wood particle board were subjected to adsorption tests to evaluate the different adsorption characteristics of each material. The following parameters were kept constant during the measurements: Temperature 20±0.5 °C. Air flow rate = 100 ml/m^3, corresponding to an air velocity of 0.35 cm/s. Inlet concentration of toluene: 10 mg/m^3.

4 Results and discussion

The result from the step change in concentration for the three materials is displayed in figure 6. It is evident that the materials exhibit widely different sorption characteristics. As can be seen, the SS-plate (stainless steel) is quickly saturated at the surface with toluene. This is a consequence of the non-permeability of this material.

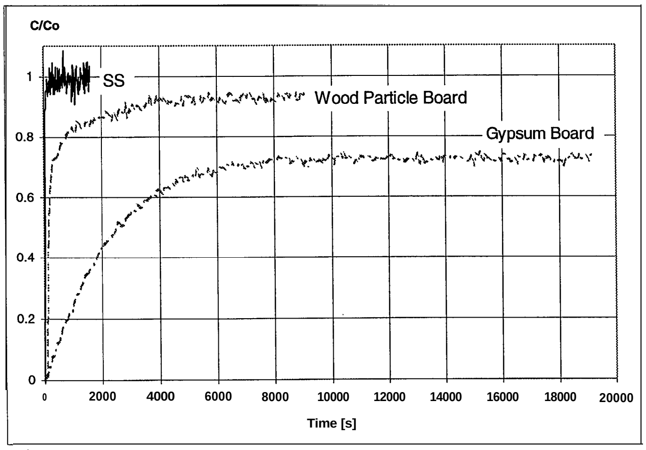

Figure 6. *Outlet concentration C / inlet concentration C_o of FLEC as a function of time for adsorption experiments. The materials were subject to identical experimental conditions*

Wood particle board (WPB) shows a moderately fast build up of toluene on the surface initially, (up to c/c_0=0.7) and a subsequent continuous transport of toluene into the material. The rate determining process in the latter sorption phase is internal diffusion. According to figure 6 gypsum board (GB) is a powerful depot for toluene. The surface of GB can accumulate appreciably more toluene compared with the other materials and the initial concentration step up is the slowest. As for WPB diffusion into the material is the rate determining process for GB after the initial step up. The experiments show that GB has the highest toluene permeability and diffusion coefficient followed by WPB. SS is non permeable for toluene. Furthermore, after the initial concentration step up one can see that only SS reaches the inlet concentration in the outlet. The other two materials approach an apparently constant sink rate. An explanation for this phenomenon may be that the solubility of toluene in WPB and GB is so large that equilibrium is far from being approached during the measurement time. This would show up as a quasi-steady-state, similar to predicted results for an irreversible sink. Another explanation could be diffusion from the interior to the edges of the material, (only one side of the material is exposed in the FLEC).

5 Acknowledgements

The authors would like to thank Mr. Erik Borgh, University College of Gävle Sandviken who completed his diploma work within this project. He participated in the development of the experimental apparatus and contributed with experimental work.

Egg tempera or water based paint?
An epidemiological study.

D. Norbäck and G. Wieslander
Department of Occupational and Environmental Medicine, University Hospital, Uppsala University, Uppsala, Sweden

Abstract
Some recent investigations have shown an increased prevalence of asthma and sick building syndrome (SBS) in newly painted buildings. Water based paints (WBP) are used in 95% of indoor painting in Sweden. New types of WBP with improved polymers, making it possible to further reduce the concentration of volatile organic compounds (VOC) in the paints, have been marketed during the 90'ies. There is also a growing interest in older types of paints, based on linoleic oil, in combination with egg or casein protein. The aim of the study was to compare asthmatic symptoms and SBS in two office buildings in the city of Uppsala, both redecorated in 1995. One building was painted with a paint based on linoleic oil and egg (egg-tempera), the other was painted with a new type of WBP low in VOCs. Both buildings had mechanical supply/exhaust air ventilation and linoleum floors. A self-administered questionnaire was distributed to all employees in March 1997. Indoor measurements of VOCs, moulds, bacteria, formaldehyde, respirable dust, CO, CO_2, NO_2, and ozone were performed in both buildings in April 1997. Statistical analysis was performed by multiple logistic regression, adjusting for possible influence of age, gender, tobacco smoking, and atopy. The indoor concentration of pollutants was low in both buildings. The prevalence of facial skin symptoms (rash or itch) was increased in the building painted with egg-tempera. No significant difference of asthmatic symptoms (wheeze or attacks of breathlessness), eye symptoms, nasal or throat symptoms, or general symptoms such as headache, fatigue or nausea was observed between the buildings. The prevalence of doctors' diagnosed asthma was 9% in both buildings. One new case of doctor's diagnosed asthma occurred in the population in egg-tempera building (N=177) after the redecoration in 1995, no new case of doctor's diagnosed asthma occurred after the redecoration in the WBP building (N=56). Perceived air quality did not differ significantly between the two buildings. In conclusion, the use of egg-tempera paint indoors, claimed to be beneficial from an "ecological" point of view, does not seem to represent any health-related improvements of the indoor environment, as compared to the new type of water based paints, low in VOCs.
Key words: asthma, egg tempera, water based paint, sick building syndrome, microbial volatile organic compounds (MVOC)

Introduction

Concern has increased about possible health effects and discomforts resulting from indoor air pollution. Disorders that have been associated with indoor air pollution include asthma, allergies, and nonspecific irritative symptoms from eyes, upper airways, and facial skin. These nonspecific symptoms are sometimes referred to as the sick building syndrome (SBS). Several epidemiological studies on such symptoms have been published, identifying possible factors related to SBS (1-4), building-related asthmatic symptoms (1), and subjective indoor air quality (1). In addition, SBS, asthmatic symptoms and the perception of indoor air quality may also be influenced by personal factors, such as female gender, tobacco smoking, psycho-social work conditions, and allergic disorders (l-4)

Volatile organic compounds (VOC), formaldehyde, and airborne aerosols have been related to health effects and building related complaints in some studies (l-4). One common source of indoor VOCs is emissions from fresh paint (5-S). Two recent studies have shown that 26-32% of the Swedish population have had the interior of their dwelling painted during the last year (5-6). There are also some indications that emissions from fresh indoor paint may increase the occurrence of upper airway symptoms (5,8), eye irritation (6,8), and asthma (6,7).

The chemical composition of indoor paints has changed drastically during the last decades. Earlier, solvent-based paints were commonly used for indoor painting in Scandinavia, nowadays about 95% of indoor paint in Sweden is water based paints (WBP) (9). The shift from solvent-based paint to water-based paint has reduced the total emission of VOCs from indoor paint, but shifted the exposure toward new types of more polar and high boiling VOCs (10). Further changes of indoor paints have taken place the last years in Sweden. New types of WBP with improved polymers, making it possible to further reduce the concentration of volatile organic compounds (VOC) in the paints, have been marketed during the 90'ies. There is also a growing interest in older types of paints, based on linoleic oil, in combination with egg or casein protein. There is, however, scarce information in the literature on how these new paints affects the indoor environment, or the inhabitants of the newly painted buildings.

Because of the lack of epidemiological studies in this field, we have performed a study on asthma, SBS, and subjective indoor air quality in two office buildings in the city of Uppsala, both redecorated in 1995. One building was painted with a paint based on linoleic oil and egg (egg-tempera), the other was painted' with a new type of WBP low in VOCs.

Material and methods

Study population and type of buildings

Both buildings were office buildings and situated 1 km from each other, in the central parts of Uppsala, a mid-Swedish municipality with about 160 000 inhabitants. The first building was an older three-storey building with the social welfare administration. It had 219 employees, and was redecorated in 1995 with a new type of water based paint, low in VOCs. The second building was an older seven-storey building with 66 employees, containing the administrative unit for the university of Uppsala. It was also redecorated in 1995, but with a paint based on linoleic oil and egg (egg-tempera). Both buildings had mechanical supply/exhaust air ventilation and linoleum floors.

Assessment of symptoms

A self-administered postal questionnaire was distributed to all employees in March 1997, off pollen season. It contained questions on personal factors such as age, sex, smoking habits, occupation, asthma, allergies, and atopy. It also contained some questions on the home environment, including building age, house pets, number of members of the family, indoor painting, presence of wall-to-wall carpets, and signs of building dampness in the dwelling.

Questions on asthma included one question on doctor's diagnosed asthma, and year of diagnosis. In addition, there were three questions on asthmatic symptoms during the last 12 months (wheeze or daytime/nighttime attacks of breathlessness), previously used in the worldwide European Community Respiratory Health Survey (ECRHS)(11).

Information on 23 symptoms compatible with the sick building syndrome was obtained from a self-administered questionnaire. The recall period was seven days. For each symptom, an answer could be given according to two options; "no" or "yes" . The symptoms were classified as: eye symptoms, nasal symptoms, throat symptoms, facial skin symptoms, and general symptoms. In addition, a symptom core ranging from 0 to 23 was constructed, by summing up the number of "yes" answers.

Finally, the questionnaire contained three 10 cm analogue rating scales on different aspects on subjective indoor air quality. The first scale was a general scale on perceived air quality (O-l 00%), the second was on perceived air dryness (O-l 00%), and the third scale (0-100%) was dealing with the perception of dustiness of the air.

Assessment of exposure

Indoor measurements of VOCs, moulds, bacteria, formaldehyde, respirable dust, CO, C02, N02, and ozone were performed in both buildings in mid-April 1997. Measurements with direct reading instruments, and pumped air sampling, were made on two different days in each building. In addition, ozone, carbon monoxide, carbon dioxide, and nitrogen dioxide was measured by diffusion sampling, for seven days. Ozone, respirable dust, and VOCs were also measured in the outdoor air, outside the buildings.

Room temperature and air humidity were recorded with an Assman psychrometer. Concentrations of respirable dust were measured by a direct reading instrument based on light scattering (Sibata P-5H2, Sibata Scientific Technology Ltd, Japan). The instrument was calibrated by the manufacturer to 0.3 µm particles of stearic acid. Indoor CO2 concentration was measured by a direct reading infrared spectrometer (Rieken RI-41 1 A, Rieken Keini, Japan), calibrated by standard gases containing known concentrations of C02. Air borne microorganisms were sampled on a sterile 28 mm polycarbonate filter (Nucleopore, Millipore Corp., USA) with a pore size of 0.4 µm, the sampling rate being 2.4 L/min, for 6 hours. The total concentration of airborne microorganisms was determined by the CAMNEA method utilizing epifluorescence microscopy. Viable moulds and bacteria were determined by incubation on two different media. The detection limits of viable microorganisms were 50 colony forming units (cfu)/m^3 of air.

Indoor concentrations of formaldehyde were measured with glass fibre filters impregnated with 2,4-dinitro-phenylhydrazine, the air sampling rate being 0.20 L/min during six hours. The filters were analyzed by liquid chromatography. Volatile organic compounds were measured by sampling on both charcoal sorbent tubes (Anasorb 747) and synthetic polymer (XAD-7), followed by a gas chromatographical masspectrometric analysis (GC-MS). VOCs of possible microbial origin (MVOC) were sampled on Anasorb 747, desorbed with 1 ml methylene chloride, and analysed by GC-MC using selective ion monitoring (SIM) (12). The sampling time was 6 hours for both microorganisms, formaldehyde, VOCs, and MVOCs.

In addition, a qualitative analysis of VOCs in settled dust was performed. Settled dust was collected by drawing a glass fiber filter over the linoleum floor surface. Collected dust was desorbed by carbon disulphide, and analysed for VOCs with the same procedure as for the air samples.

Statistical analysis

The prevalence of symptoms in the two groups was compared with chi-2-analysis. The ratings of indoor air quality was compared by means od Student's t-test.Differences in exposures were tested by Mann-Whitney U-test. Multivariate statistical analysis was performed by multiple linear or logistic analysis with the SPIDA statistical package (the Statistical Laboratory, Macquarie University, Australia). Multiple logistic regression analysis was applied to study relationships between indoor environment and symptoms. Multiple linear regression analysis was used to study relationships between indoor environment, and the outcome from rating scales for subjective indoor air quality. Control was made for possible confounders: age, gender, smoking habits, and atopy. Adjusted odds ratios (OR), with a 95% confidence interval (CI) were calculated, adjusting for possible influence of age, gender, tobacco smoking, and atopy.

Results

Totally, there were 219 employees in the building painted with egg tempera (ET-building), 177 participated (8 1%). There were 66 employees in the building painted with water based paints (WBP-building), 56 participated (85%).

Personal factors

The distribution of personal factors was similar in the two groups. The mean age among the participants was 48 years in the ET-building, and 47 years in the WBP-building. The prevalence of females, current smokers and atopy was 73%, 18% and 3 1% respectively, in the ET-building. The corresponding figures were 88%,14%, and 30% in the WBP-building. None of these differences were statistically significant.

Measured indoor climate

Indoor climate was similar in the two buildings. Average room temperature was 22.9 ° C (21.5-24.0 °C) in the ET-building and 22.6°C (21.5-23.5 °C). Average relative air humidity was 23% (range 17-33%) in the ET-building, and 26% (range (17-37%) in the WBP-building. The average level of CO_2 was 580 ppm (500-700 ppm) in the ET-building, and 600 ppm (480-800 ppm) in the WBP-building.

Exposure measurements

Indoor concentration of NO_2 and CO, two traffic exhausts related pollutants, was significantly higher in the building painted with water based paint (Table 1). In contrast, the indoor concentration of volatile organic compounds of possible microbial origin (MVOC) was significantly higher in the building (Table 2). The outdoor concentration of MVOC did not differ between the two buildings. The average concentration of viable bacteria was 100 colony forming units (cfu)/m^3 in the ET-building and 140 cfu/m^3 in the WBP-building. The concentration of viable moulds was 50 cfu/m^3 in the ET-building, and 180 cfu/m^3 in the WBP-building.These differences were not statistically significant. Moreover, no significant differences in the concentration of total moulds or total bacteria were detected between the two buildings. Among viable moulds, *Penicillium* species were detected in the air both buildings, *Cladosporium* sp. were detected in the ET-building, only.

Table 1 Indoor and outdoor concentration of selected pollutants in the two buildings

Compound	ET-building M(min-max)	WBP-building M(min-max)
Indoor respirable dust (μg/m^3)	5 (4-7)	6 (5-8)
Indoor ozone (ppb)[a]	10.5(5.9-16)	16.7(7.1-37)
Outdoor ozone (ppb)	31	35
Indoor nitrogen dioxide (μg/m^3)	6(4-12)	14(12-18)**
Indoor carbon monoxide (ppm)	0.08(0.06-0.12)	0.15(0.12-0.18)*
Indoor formaldehyde (μg/m^3)	3.7(2-7)	4.5(4-6)

* $P<0.05$;** $P<0.01$ Significant difference between the two buildings by Mann-Whitney U-test

Table 2 Concentration of selected compounds of possible microbial origin (MVOC)

Type of compound	ET-building M(min-max)	WBP-building M(min-max)
Sum of indoor MVOC ($\mu g/m^3$)	0.38(0.26-0.42)	0.27(0.22-0.32)*
Sum of outdoor MVOC ($\mu g/m^3$)	0.04	0.08
Indoor 3 -methylfuran ($\mu g/m^3$)	0.02(0.016-0.02)	0.01(0.01-0.016)**
Outdoor 3-methylfuran ($\mu g/m^3$)	0.005	0.01
Indoor 1-octen-3-ol ($\mu g/m^3$)	0.07(0.04-0.10)	0.04(0.04-0.05)*
Outdoor 1 -octen-3-ol ($\mu g/m^3$)	0.003	0.02

* $P<0.05$;** $P<0.01$ Significant difference between the two buildings by Mann-Whitney U-test

Subjective indoor air quality

The perception of the indoor environment, and occurrence of medical symptoms was similar in the two buildings (Table 3).

Table 3 Subjective indoor air quality in the two buildings

	ET-building (M±SD)	WBP-building (M±SD)
Perceived air quality (0- 100%)	55±20	54±21
Perceived air humidity (0- 100%)	33±17	36±17
Perceived dustiness of the air (0-100%)	44±23	51±22

No significant differences between the two groups

SBS-symptoms

The prevalence of facial skin symptoms (rash or itch) was increased in the building painted with egg-tempera. No significant difference of asthmatic symptoms (wheeze or attacks of breathlessness), eye symptoms, nasal or throat symptoms, or general symptoms such as headache, fatigue or nausea was observed between the buildings.

Table 4 Subjective indoor air quality in the two buildings

Type of weekly symptoms	ET-building (%)	WBP-building (%)
At least one eye symptom	47	52
At least one nasal symptom	45	42
At least one throat symptom	39	43
At least one facial skin symptom	13	2**
At least one general symptom	67	71

** P<0.01 by chi-square test

Asthma and asthmatic symptoms

The 12 months' prevalence of asthmatic symptoms (wheeze or attacks of breathlessness) was 19% in the ET-building and 18% in the SBP-building, a non-significant difference. The prevalence of doctors' diagnosed asthma was 9% in both buildings. One new case of doctor's diagnosed asthma occurred in the population in egg-tempera building (N=177) after the redecoration in 1995, no new case of doctor's diagnosed asthma occurred after the redecoration in the WBP building (N=56).

Discussion

The design was cross-sectional and in such studies, selection effects may cause both underestimation and overestimation of the true relationship. Selection bias due to low response rate is less likely since the participation rate in the postal questionnaire was high (81-85%). The true adverse health effect of indoor painting could, however, been underestimated if there were a health based selection.

In conclusion, the use of egg-tempera paint indoors, claimed to be beneficial from an "ecological" point of view, does not seem to represent any health-related improvements of the indoor environment, as compared to the new type of water based paints, low in VOCs.

SUBJECTIVE INDOOR AIR QUALITY IN GERIATRIC HOSPITALS

K. Nordström, D. Norbäck, G. Wieslander and R. Wålinder
Department of Occupational and Environmental Medicine, University Hospital, Uppsala University, Uppsala, Sweden

Abstract
There is a need for field studies, identifying buildings with a high proportion of inhabitants satisfied with the indoor environment. Building dampness in the floor construction is known to cause chemical degradation of PVC-floor coatings, but few epidemiological studies on this topic have been pubished. Another topic of interest is indoor air quality in "ecological buildings", with unconventional building materials and architectural designs. The aim of our study was to compare subjective indoor air quality in four geriatric hospital buildings, selected to represent buildings with different age and design, irrespectively on the degree of complaints. The first building was built in 1925, and redecorated in 1955. The second building, built in 1985, had known dampness in the floor construction. The third building was built in 1993, with conventional building technique. The last building was an "ecological building" built in 1995, in accordance with anthroposophic principles. All staff (N=95) was requested to answer a questionnaire, with questions on subjective indoor air quality, 88 participated. Indoor measurements of room temperature, relative air humidity, air flow rate, illumination, VOCs, moulds, bacteria, formaldehyde, respirable dust, CO, C02, N02, and ozone were performed in all buildings. Statical analysis was performed by multiple logistic regression, adjusting for possible influence of building age, age of the subjects, gender, tobacco smoke, and atopy. Dampness in the upper concrete floor surface (75-84%), ammonia under the floor (3 ppm), and 2-etyl-1-hexanol in the air were detected in the two buildings built in 1985 and 1993. Complaints on air dryness and stuffy air were significantly more common in these damp buildings. The anthroposophic building had significantly less complaints on stuffy air, dry air and static electricity, as compared to all the other buildings. The average room temperature was 22.5-23.0 ^{0}C in the two damp buildings, 22.5 ^{0}C in the anthroposophic building, and 22.0 ^{0}C in the oldest building. All buildings had very low levels of formaldehyde, moulds, and bacteria. In conclusion, building dampness in the floor construction, may increase the sensation of air dryness and stuffy air. In contrast, architectural design and building materials used in the anthroposophic building may increase the proportion of satisfied inhabitants.
Keywords: indoor air quality, damp buildings, "ecological building", geriatric hospital, 2-etyl-1-hexanol, dry air, stuffy air.

Introduction

Complaints on poor indoor air quality may comprise a sensation of dryness, stuffy air, temperature discomfort, draught, noise, and static electricity. These complaints are common (1,2,3,4). Subjective indoor air quality has mainly been investigated among office workers or in the general population. Both the Danish Town Hall study (1) and the-Swedish Office Illness Project (3) have shown that many office workers are dissatisfied with the indoor air quality.

The perception of poor indoor environment, particularly air dryness, and stuffy air is related in the sick building syndrome, as defined by a working group of the World Health Organization (5). This syndrome comprises irritative symptoms from eyes, skin and upper airways as well as general symptoms such as headache and fatigue. Such symtoms are common in hospital workers (8). To improve the indoor air quality in hospitals, there is a need to identify factors related to the perception of good indoor air quality.

The aim of the study was to evaluate relations between perceived air quality and the physical indoor environment in hospitals.

Material and Methods

Subjects

The study was performed in the county of Ystad in southern Sweden. Four geriatric hospitals with different ages were selected with different age and design. The first building was built in 1925, and redocorated in 1955. The second building, built in 1985, had known dampness in the floor construcion. The third building was built in 1993, with conventional building technique. The last building was an “ecological building”, built in 1995, following antroposophic principles. All staff (N=95) were included in the study population. The study base was the study population observed during three months.

Assessment of subjective indoor air quality

To evaluate the perception of dry air, stuffy air, odour, annoyance from environmental tobacco smoke (ETS), temperature, draught, static electricity and noise, the personnel were asked to answer a standardized self-administered questionnaire. The questionnaire has been used in Sweden for some years and most of the qustions have been validated previously. The current version, with the designation MM040NA, was developed by the Department of Occupational Health in Örebro, Sweden (6), and has been used in the large Office Illness Study in northern Sweden (3). It contains questions on subjective indoor air quality, sick building syndrome (SBS), personal factors and the psychosocial climate of the workplace. A recall period of three months was used in the questionnaire. For each perceived climate variable, there were three alternatives to answer, “no, never”, “yes, sometimes”, and “yes, often”. Often means every week. The prevalence of weekly complaints was calculated for each subjective climate variable. The questionnaire was distributed to each hospital worker at the workplaces in January 1997, and were answered within two weeks.

Assessment ofpersonal factors and exposures in the home

Information on age, gender, smoking habits, hay fever and asthmatic symptoms was obtained from a questionnaire. The current version of the questionnaire contained four different questions covering different aspects of the psychosocial work conditions.

In a questionnaire on exposures in the home there were questions about building age, dampness, carpets, repainting and new floor last twelve months, and smoking habits and subjective indoor air quality at home.

Assessment of exposure

The technical investigation comprised a building survey and measurements of dampness in the floor, room temperature, air humidity, exhaust air flow, illumination, and the levels of carbon dioxide (CO_2), carbon monoxide (CO), nitrogen dioxide (NO_2), formaldehyde, other volatile organic compounds (VOC), ozone, moulds, and bacteria. In the building survey, information was gathered on building age, types of building material, types of ventilation system, signs of building dampness and smoking restictions in the building.

The moisture content in the upper concrete floor surface was measured by a Waisala moisture instrument with probe HMP36. The instrument was calibrated with a solution of KSi04 and NaCl. Dampness in the floor was also indicated by a directreading dampnessindicator. Measurements of room temperature and relative air humidity were performed by a termohygrograf (CASELLA T 9420) during two weeks in each building. The thermohygrograf was calibrated by comparison a sling psychrometer. The exhaust air flow was measured in fifteen hospital rooms in each building by a thermoanemometer (ALNOR GGA 65 P). The thermoanemometer was calibrated by the Swedish National Institute of Building Research before the measurements. The illumination was measured in ten points in each building by Hagner’s instrument.

Nitrogen dioxide, ozone, carbon monoxide, carbon oxide and formaldehyde were sampled with passive sampling during seven days in the buildings. Four measurements in each building. Ozone was also measured in the outdoor air. Nitrogen dioxide was sampled with a passive sampling badge obtained from Toyo Roshi Kaisha, Ltd. and was analysed by liquid chromatography. Carbon monoxide was measured by a passive colorimetric detector tube (Dräger 50/a-D). Carbon dioxide was also measured by a passive colorimetric detector tube (Dräger 1 %/a-D).

Volatile organic compounds were sampled on different media (charcoal sorbent tubes Anasorb 747, and XAD-7), with four measurements in each building. The air sampling rate was 200 ml/min during six hours. The charcoal tubes were desorbed with one ml of carbon disulphide, and analysed by gas chromatography and mass spectrometry (GC-MS). Volatile organic compounds were also measured with passive sampling during seven days in each building. Airborne microorganisms were sampled on 25 mm nucleopore filter with a pore size of 0,4 mm and a sampling rate of 1,5 l/min for six hours. The total concentration of airborne microorganisms was determined by the CAMNEA method . Viable moulds and bacteria were determined by incubation on two different media. Four measurements in each building.

Temperature, air humidity, volatile organic compounds, carbon monoxide, carbon dioxide, formaldehyde, nitrogene dioxide, ozone and airborne microorganisms were measured 1.5 meter above the floor, during the study period.

Statistical Methods

Analysis of relations between subjective air quality, questionnaire data and exposures were undertaken with multivariate statistical methods. Multiple logistic regression analysis was performed in several steps using the SPIDA statistical package. Control was made for possible confounders: building age, age of the subjects, gender, smoking habits, and atopy. In all statistical analyses, two-tailed tests and a significance level of 5% were used.

Results

Personal characteristics

Totally, there were 95 personnel in the four geriatric hospitals, 88 participated (93%). The frequence of woman was 95%. The prevalence of hayfever was 16%, and 10% of the subjects reported that they ever have had asthma. The prevalence of current smokers was 3 1%. The psychosocial climate or the exposures in the home did not differ significantly between the buildings.

Buildong characteristics

The first building was built in 1925, and redocorated in 1925. The second building, built in 1985, had known dampness in the floor construction. The third building was built in 1993, with conventional building technique. The last building was an "ecological building", built in 1995, in accordance with antroposophic principles. All buildings were built of concrete or bricks, with slanting tile roofs, and all had openable windows. Building B was equipped with mechanical ventilation with both supply and exhaust air (mixed system) in the hospital rooms. The three other buildings had only mechanical ventilation in exhaust air. There were no air humidification or air cooling devices. The floor coatings consisted of poly-vinyl-cloride (PVC) material in all buildings except the antroposophic, which had linoleum and clinker.

Measured indoor climate

The average room temperature was 22,0 - 23,0 ^{0}C in the buildings. The antroposophic building had 22,0 ^{0}C. Average relative air humidity was 37% in the oldest building with the lowest air rate, and 30 – 33% in the other buildings. The exhaust air flow in the hospital rooms were between 16 and 68 m^3/h in the different buildings, where the buildings with conventional buildings technique had the highest ventilation flow. (table 1)

Exposure meausurements
Dampness in the upper concrete floor surface (75-84%), ammonia in the floor (3 ppm) and 2-etyl-1-hexanol in the air were detected in the two buildings built in 1985 and 1993 (table 1). The two other buildings had lower concentrations of these compounds. All buildings had very low levels of the other chemical and biological emissions. The average ozone concentration was 1.2 – 8.5 ppb and the average NO2-concentration was 7 – 11 ug/m^3 in the four buildings. The formaldehyde concentration was 2.0 – 7.0 ug/m, the CO-concentration was 0.16 – 0.24 ppm and CO2-concentration was 610 – 960 ppm as a average in the buildings. These concentrations were average values during 7 days.
The average concentration of viable bacteria was 50 – 80 colony forming units (cfu)/m^3 and the average concentration of viable moulds was 80 – 160 cfu/m^3 between the different buildings. The concentration of 2-etyl- 1 -hexanol was 19.8 ug/m^3 and 4.8 ug/m^3 in the two buildings with dampness. The concentration was higher in the newest building.
The average illumination was 85 – 195 lux in the different buildings.

Table 1 Measured indoor climate and exposures in the four buildings.

Type of exposure	Building A	Building B	Building C	Building D
Building age	1925	1985	1993	1995
Average room temperature	22.5 ^{0}C	23.0 ^{0}C	22.5 ^{0}C	22.0 ^{0}C
Indoor air humidity	37 %	33 %	30 %	31%
Dampness in floor surface	58 %	84 %	75 %	69 %
Ammonia in floor	0 ppm	3 ppm	3 ppm	0.5 ppm
Exhaust air flow in room	16 m^3/h	59 m^3/h	68 m^3/h	45 m^3/h
2-etyl- 1-hexanol	<1 ug/m^3	4.8 ug/m^3	19.8 ug/m^3	<1 ug/m^3
CO2 (7 days)	960 ppm	610 ppm	680 ppm	740 ppm

Perceived indoor quality
The most prevalent discomfort was a sensation of dry air. In total, 65% reported weekly complaints of dry air. Complaints on stuffy air and static electricity were also common, (Table 1).

Table 2 Three months prevalence of weekly complaints on indoor air quality in different buildings.

Variable	Prevalence (%)				
	Building A	Building B	Building C	Building D	Total
Draught	23	40	67	9	35
Dry air	62	78	94	26	65
Unpleasant odour	23	13	6	17	14
Static electricity	0	42	39	13	27
Passive smoking	0	9	11	0	6
Inadequate light	8	16	6	9	10

Building factors related to subjective indoor quality

The perception of indoor air climate was related to anthroposophical building, dampness in the concrete upper floor and emissions of ammonia in the floor and 2-etyl-1-hexanol in the air.

Complaints on air dryness and stuffy air were significantly more frequent in damp buildings and ammonia in the floor (table 3). On the other hand, there were less complaints on air dryness and stuffy air in the anthroposophic building. Complaints on unpleasant odour was not related to any factor.

Ventilation factors related to subjective indoor quality

Subjects, who worked in buildings with higher ventilaton flow, complained more often on draught. Complaints on air dryness and stuffy air were also more common in buildings with higher ventilation flow, but these buildings were damp buildings.

Perception of static electricity

Percepton of static electricity was more common in buildings with higher ventilation flow, and significantly less common in the anthroposophic building.

Table 3 Adjusted odd ratios (OR) with 95% confidence interval for relations between subjective indoor climate, and ecological building, dampness in the upper floor, ammonia in the floor and exhaust air flow.

Subjective indoor climate variable	Anthroposophic building OR (95%)	Dampness in the upper concrete floor OR (95%)	Ammonia in the floor OR (95%)	Exhaust air flow OR (95%)
Draught	ns	ns	ns	1.2 (1.0-1.4)
Stuffy air	O.l(O.Ol-0.4)	10.5(1.9-56.5)	2.5(1.3-4.7)	l.O(l.O-1.3)
Dry air	0.1(0.02-0.3)	10.2(3.0-34.9)	2.5(1.5-4.0)	1.1(1.1-1.2)
Unpleasant odour	ns	ns	ns	ns
Static electricity	0.1(0.02-0.5)	-		l.l(l.O-1.2)

Discussion

Our study show that complaints on poor indoor quality are common and was related to building dampness in the construction. Complaints were particularly common on dry air, stuffy air and static electricity. In contrast, the workers in the antroposophical building and also in the oldest building were more satisfied with the indoor air quality. This could not be explained by differences in psychosocial environment or exposures in the home.

Complaints on dry air, stuffy air and static electricity were more common in the two buildings with dampness. In an earlier study among hospital workers in southern Sweden (7), 87% of the employees complained on dry air and 44% on stuffy air. In this study (7), sensation of dry air was more common in buildings with a high ventilation flow, and also related to building dampness in the concrete slabs. Other investigators have mainly studied complaints in office workers, and there is scare information on perceived air quality in hospitals available in the literature. In comparison with the Danish Town Hall Study (1), and the Office Illness project in northern Sweden (3), complaints on dry air and stuffy air were more common in the two buildings with dampness in our study. In the Town Hall Study, 52% of the females complained on dry air and 41% complained on stuffy air. Similar figures were obtained in a study from northern Sweden (3), where 43% of the females had weekly complaints on dry air. In this study in northern Sweden there was also a relation between air dryness and building dampness. In contrast, the subjects in the anthroposophic building in our study had less complaints on stuffy air, dry air, and static electricity than in the above studies.

The levels of formaldehyde, moulds, N02, CO, C02, and bacteria were very low in our study in comparison with schools (9).

In our study we could identify certain physical factors that could be improved in order to obtain a good subjective indoor air quality in hospitals. The most important way is that dampness in the floor construction must be avoided to reduce emissions like ammonia in the floor and 2-etyl-1-hexanol in the air.
In contrast architectural design and building materials used in the anthroposophic building may increase the proportion of satisfied inhabitants.

ABSTRACT
The indoor climate of moisture damaged buildings have proved to be the cause of many building related illnesses (BRI), reported in the scientific literature. Two case studies are presented where the buildings suffered from extent mold- and bacterial growth within the building construction. This was shown through MVOC analysis of the indoor air and microbial analysis of building material. In both cases, a modern ventilation system failed to improve and prohibit "sick-building"-syndrome (SB S) symptoms of the users of the building. It was found through tracergas-technique the utmost importance of understanding the movement of odor molecules to find the emission source. Only if the emission source is found, then it is possible to mitigate a "sick building" in an efficient way.

Molds, bacteria, microorganisms, ventilation, SB S,

INTRODUCTION

The occurrence of damp buildings can be caused by water leakage, insufficient ventilation, systematic mistakes in the building construction and so on. Too much moisture in the building sooner or later leads to building damages. In Sweden these damages are seldom visible and more often they occur within the building construction or behind different surface layers as PVC-carpets, water vapor barriers etc.

Beyond rotting damages, which is the lesser part of water damages, the majority of these consists- of moldy or bacterial growth and/or increased chemical emissions. These occur as different decomposing mechanisms will initiate that, if building material is exposed to too high moisture stress in combination with other chemical factors.

Moisture related building damages usually leads to some kind of emission, such as bio-emission from microorganisms (MVOC, MPOM) or chemo-emissions from building material (VOC). These emissions can cause irritation or initiate building related illnesses of the users of the building.

A common opinion is that a well functioning HVAC-system will take care of these emissions and transport them out of reach to prohibit an impact on the users of the building. Instead of focusing on the proper function which is to supply the users of the building with air of good quality, with enough oxygen, low carbondioxide, adequate moisture and temperature. Another important aspect is to export excessive moisture (protects the building material) , carbondioxide and other by-products created by different human activities.

The HVAC system is not designed to make a “Sick building” healthy.

Common knowledge and “truth’ among field practitioners today is that moisture damaged material should be replaced, whether it is a material being damp at present or if the dampness is old and has dried out. This has also been shown as early as in 1988 (Norbäck and Widström) However, all parts of a building can not be replaced. A change of the fundamentals of e.g. concrete construction would be the same as to take down the a whole building. This action would be, if not unrealistic at least a very expensive way.

In order to reduce the emissions of “sick buildings”, the installment of a well functioning ventilation system have been a common mitigating step in communal buildings. In Sweden, a lot of schools have been remediated this way. This has however not been proved to be successful (Norbäck et al. 1998). A review article from Godish & Spengler also confirmed this in 1996.

The movement of the emissions from moisture damaged building material and microbial growth seldom follows the air movement intended in HVAC-systems. The emissions seems more to follow the laws of diffusion and chemical solubility in different surface layers, such as water vapor barriers and PVC-/linoleum carpeting.

The results of investigating some problem buildings by describing their abiotic and biotic parameters have given another perspective on the benefits of HVAC-systems.
In Scandinavia we have a quite a number of problem buildings, with odor problems and SBS of the occupants where the deposit of emission products not have been anticipated.

INVESTIGATION

CASE 1. A FAMILY HOUSE IN THE MID-EAST OF SWEDEN

The building was renovated and let out to a family of two adults and two children. Shortly after, they started to show strong SBS-symptoms, mainly extreme fatigue. Seventy-five percent of the family needed to sleep1 6 to 18 hours per day, but were still feeling drowsy. The local health care unit sampled MVOC-probes in building. The impact of microbial volatile bio-emissions was investigated by sampling the indoor air on synthetic carbon. The samples were extracted by dichloromethane. The analysis were then performed with a HP 5890 gas chromatograph equipped with a HP 5971 mass-selective detector. The analytical method were performed according to Ström et.al., 1994, except for the length of the column, which were changed to a 60 m capillary column The results are shown in table 1.

Table 1 .The concentration of volatile microbial makers of the indoor air of the building in case 1, before remediation.

Location	Mvoc 1 µg/m³ air	MVOC 2 µg/m³ air
Ref out	0,024	0,50
Basement	0,21	4,65
1st floor	0,47	5,58
1st floor	0,65	7,41
2nd floor	0,79	2,55
2nd floor	0,67	8,53
Ref.building	0.15	1.5

The concentration of volatile organic compounds representing microbial activity.
MVOC 1, the sum of the most common original "unique" microbial volatile compounds.
MVOC 2 is the MVOC 1 value, where 1-butanol and 2-methyl-1-propanol have been included.

The impact of MVOC was mainly on the 1st and 2nd floor. To establish the degree of microbial damage, the microbial biomass was investigated in representative surface areas or volumes of collected samples of building material from case 1 (Ström et al., 1994).
The results show heavily contaminated samples in the walls, while the floor construction was only slightly infected (table 2).

Table 2. Microbial biomass in the building material from case 1.

	Ref. wall area	Building wall volume	Ref insulation volume	Floor volume	Basement	
					Wall/area	Floor/area
Total fungi	$1.3*10^3$	$2.2*10^7$	$1.5*10^4$	$1.0*10^5$	$3.0*10^5$	$1.2*10^4$
Viable fungi	$1.1*10^2$	$1.6*10^2$	$1.2*10^3$	$1.3*10^3$	$9.0*10^4$	6
Total bacteria	$1.6*10^4$	$1.5*10^8$	$1.3*10^3$	$7.5*10^4$	$2.3*10^6$	$6*10^3$
Viable bact	$2.6*10^2$	$2.5*10^6$	$5.3*10^2$	$4.0*10^2$	$3.9*10^5$	6

Microbial biomass as numbers/cm' or gram.

This showed and confirmed the connection between MVOC analysis and the microbial analysis of the building material.

About ninety percent of the building above the basement was removed and a new building was erected.

In the new building, a ventilation system with heat exchange, supply- and exhaust air was installed.
In the basement there were some minor repairs based on the results of the microbial analysis.

The family moved back and soon thereafter, the SBS-symptoms returned.

Another sampling of MVOC-probes was made. The MVOC measurements after the building had been rebuilt however showed that a powerful source of bio-emissions remained (table 3.) This could be explained by that the chimney effect and the laws of gas-diffusion had not been considered properly as the highest concentration of MVOC still prevailed on the top floor.

Table 3.The concentration of volatile microbial markers of the indoor air of the building in case 1, after remediation.

Location	MVOC 1 µg/m³ air	Mvoc 2[1] µg/m³ air
Ref out	0,04	0,08
Basement	0,57	10,92
1st floor	1.32	11.83
2nd floor	1.44	13,34
Ref.building		

The concentration of volatile organic compounds representing microbial activity.
MVOC 1, the sum of the most common original "unique" microbial volatile compounds.
MVOC 2 is the MVOC 1 value, where 1-butanol and 2-methyl-1-propanol have been included.

Further investigations revealed severe microbial growth under the carpeting of the basement floor Wooden details nailed to the lower parts of the basement had similar growth on the contact surface to the wall. Emissions from PVC-carpets glued to the concrete surface in the basement were also shown.

CASE 2. A HOSTEL IN THE MID-CENTER OF SWEDEN

The personnel working in the hostel complaints over bad indoor air quality and suffer from SBS-symptoms.

The healthcare center of the Dalecarian sampled MVOC-probes in the building. The results (table 4) indicated microbial problems, and that apartment 112 had the highest MVOC-concentration of the sampled locations,

Table 4. The concentration of volatile microbial markers of the indoor air of the building in case **2**, before remediation.

Basement	0,075	1.58	0.012	0.044	0,020

The concentration of volatile organic compounds representing microbial activity.
MVOC 1, the sum of the most common original “unique” microbial volatile compounds. MVOC 2 is the **MVOC** 1 value, where **1-butanol** and **2-methyl-1-propanol** have been included.

The building had an old and a new built part. The old part has a basement while the new part is on a concrete slab with underlying insulation

The investigation showed a profound microbial growth in organic material placed between, the concrete slab and the floor construction of chipboard in the newly built part. At this location the peak value of **MVOC** and the microbial biomass had high correlation.

The personnel spend a small part of their working hours in the new building with the high **MVOC** and microbial biomass. Still they suffer from SBS-symptoms, even in the older part of the building.

However, no microbial growth could be detected in that part of the building.

Through the use of tracergas it was shown that there were no leakage through the ventilation aggregate, neither inner nor outer leakage.

Tracergas (Sulphurhexafluoride **SF_6**) was dosed at floor level in apartment 112 on 1st floor(fig.3).

The spreading of the tracergas was measured in three sample locations (fig. 4) .

Fig. 3. Dosing- and samplepoints in the Dalecarian hostel.

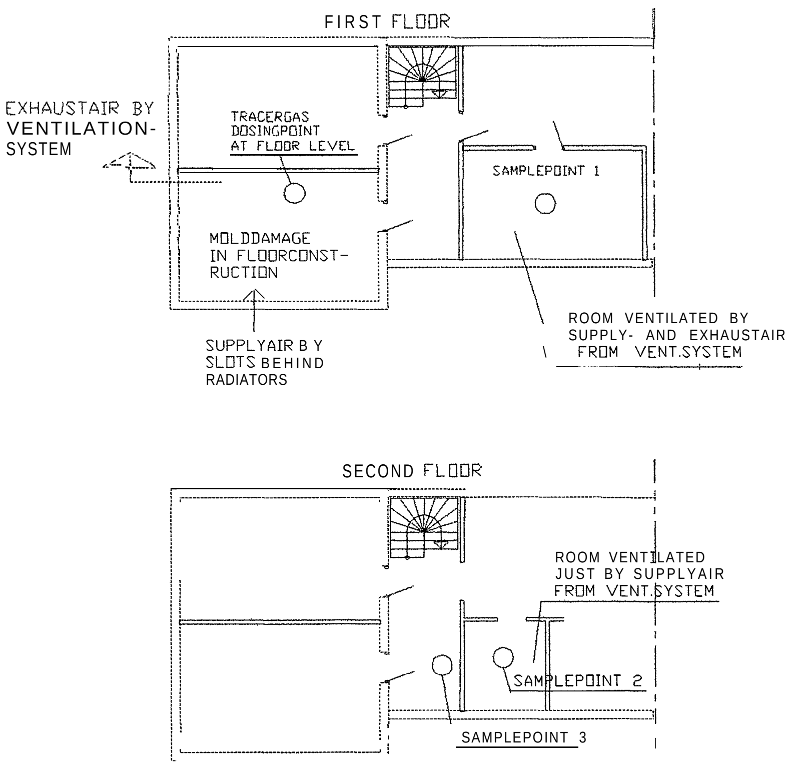

Figure 4. Tracergas movement in a hostel in Dalecarian,
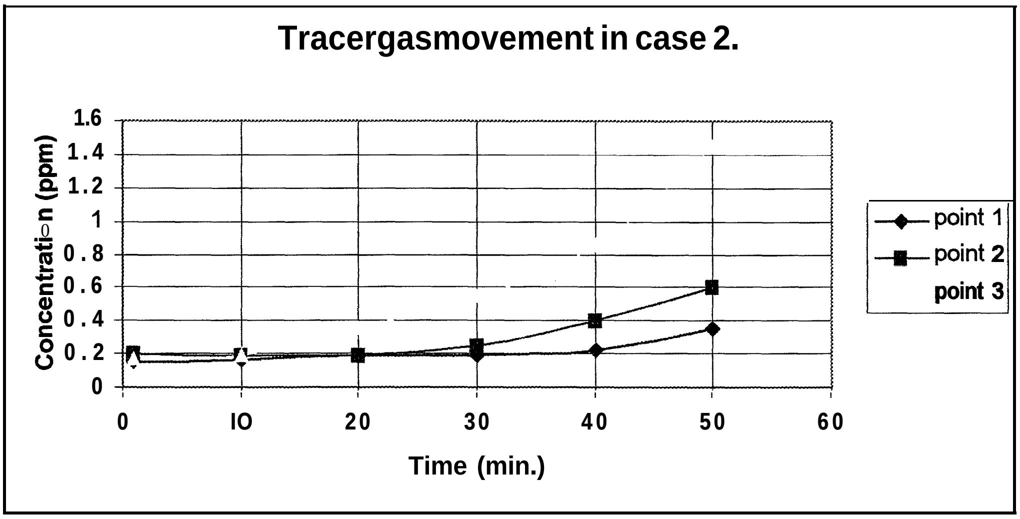
point 1=Livingroom 1st floor; point 2=Office 2nd floor; point 3=Hall 2nd floor



point 1.	Ventilated supply- and exhaust air.
point 2.	Only supply air.
point 3.	Unspecific ventilation.

After 10 - 15 minutes, tracergas could be detected in all sample points. The hall on 2^{nd} floor was first to receive tracergas. The highest concentration was also found at this spot.
The office (point 2) also received a large quantity of tracergas in spite of the fact that this room only had supply air. It was anticipated that this room should not receive any tracergas. This result is remarkable due to the functioning of the ventilation system. It is also quite interesting to note that the tracergas has a high molecular weight (M_w 146). It is in the same range as many MVOC:s, e.g. mushroom smell, 1-octen-3-ol (M_w 134).

DISCUSSION

These examples show the difficulties in pointing out an emission source. There is a must to make a highly qualified follow-up of analytical data in order to avoid unnecessary costly remediating actions.

In houses on a concreteslab with heatinsulated floor construction on top, mold-/bacterial damages is not unusual in the floor construction. A common way to mitigate such houses is to remove the floor construction, place a moisture barrier of high density (HD) polyetene on concreteslab after careful cleaning and building a new floor construction on top. The HD polyetene sheet is usually folded along the outer and inner walls to allow the construction air to reach the indoor environment.

This method protects the new floor construction from dampness, but will not handle the emission source that has been created in the concrete slab. The result of this is that the odor problem will return after costly renovations. Consequently a floor construction, ventilated with supply- and exhaust air, which will take care of the emission from the concrete slab have to be installed.

It has been shown that odorous compounds from moldy building material penetrate thick HD-polyetene (Ström et al., 1994). This means that negative air pressure is not a reliable solution to inhibit odor transport. Besides the negative air pressure there is a need of an airflow, which will decrease the concentration in the ventilated floor thereby decreasing the diffusive transport through the layer of HD-polyetene. If the airflow is too low, there is a high risque that the emission of odorous substances will reach the indoor air and thereby be the cause of another outbreak of SBS-symptoms.

These examples also show that indoors environmental problems seldom are solved through ordinary ventilation systems. Even a specifically designed ventilation system will not prevent unwanted air to reach certain locations in the building.

ACKNOWLEDGEMENTS
We wish to dedicate this report to the memory of Gunnar Eckerbom a colleague and friend who tragically passed away too soon after a period of serious illness.

New function for indoor air quality evaluation

Q. Chen
Institute of Building Physics, Chongqing Jianzhu University, Chongqing, China

Abstract

This paper is derived a functional expression for evaluating the indoor air quality from the generalized Weber-Fechner's law and the Fanger's "Olf method", as well as the German VDI methed. From the generalized Weber-Fechner's law we have derived the room articulation function, the visual visibility function and the thermal comfort function which are agreement with the tested results which had published by the famous researchers in the world.[1] So that it can be declared the success for finding the function for evaluating the indoor air quatity once again. And the present paper shows the generalized Weber-Fechner's law to hold, that in the generalized Weber-Fechner's law has found a differential equation as

$$dp = kf(p)dR/R^{m} \qquad (I)$$

where p = the sensible variable; f(p) = a certain arbitrary function of P to be determined by fiting the tested curve; R is the physical excited variable; k is a constant coefficient which can be balanced unit system in the equation; m is a index.

As f(P)=1, m=1, It had been called the Weber-Fechner's law. It was well known in a some text books such as [2]. For solving concrete problem, it must be determined the function f(P) and the index m, which can be found by using the data from the tested curve.

In this olfactory case we have got the function f(P) to be a function of two factors i.e. P and (a+bP). The first factor P is expressed the smell change exponentially ; the second factor (a + bP) is corrected the olfaction changed sharply at low concentration and dully at high concentration. The value m must keep minus sign which make P = 0, since it can keep at no smeller while no body complains.

The resultant form of the derived theoretical formula can express as simple as following

$$P = P_{\triangle}/(1 - \Omega P_{\triangle}) \qquad (II)$$

where an exponential function: $P_{\triangle} = 100\, e^{-4.248R^{-1}}$ and a constant $\Omega = 1.45\times10^{-3}$.

Keywords: Air Quality evaluation, Fanger's olf method, German VDI method, theoretical calaulation method, olf function.

1 Introduction

Evaluating indoor air quality is one of many difficult problem in the world. Due to human smell is decay with time; it is said, as me going to the sweet room the sweet must disappear gradually with time duration; similarly, as one going to a stinking room, the stinking can disappear gradually with the time duration. But whatever human smell is still a objective basis. So that the smell measurement must control time interval within the maximum acute sense of smell.

Under strictly controlled conditions the Fanger's "olf method" and the German VDI method were practised. These two methods give the same comparable result. This paper is derived a theoretical formula from the generalized Weber-Fechner's law which is attempted to show the theoretical proof.

2 From tests to theory

2.1 Fanger's olf function

The Fanger"olf method" is defined the pollutant to indoor air from one standard person as "1 olf", that in one room with a fresh air rate 10 l/s, it is defined as "1 decipol" polluted level.

the olf values for some pollution sources as shown in Table 2.1

Table 2.1. The olf values for some pollution sources

The pollution source	Statement	The olf values
Sedentary person	1 met	1 olf
Active person	4 met	5 olf
Active person	6 met	11 olf
moker, when smoking		25 olf
amoker, average		6 olf
materials in offices		0.05 olf/m^2 floor

The pollution level decipol is an unit pollution intensity in indoor air. Put R is a phycical excitation for smell. The PD is the subjects percentage to complain dissatisfaction. The tested curve is shown the relationship between R and PD, as shown in Figure 1.[2]

2.2 The German VDI method

This method is adopted olfactometer to measure the indoor air quality; it is taken the volatile acetone as smeller, and the value is in concentration of acetone ppm, which can be found the correspondent value in decipol, as shown in Figure 2. With acetone concentration evaluated indoor air quality had translated into the Fanger's Curve, as shown in Figure 3.

It can be seen the results from the two different methods have the same efficiency, since the smell of human being has adaptability, that make the smell to disappear with duration.

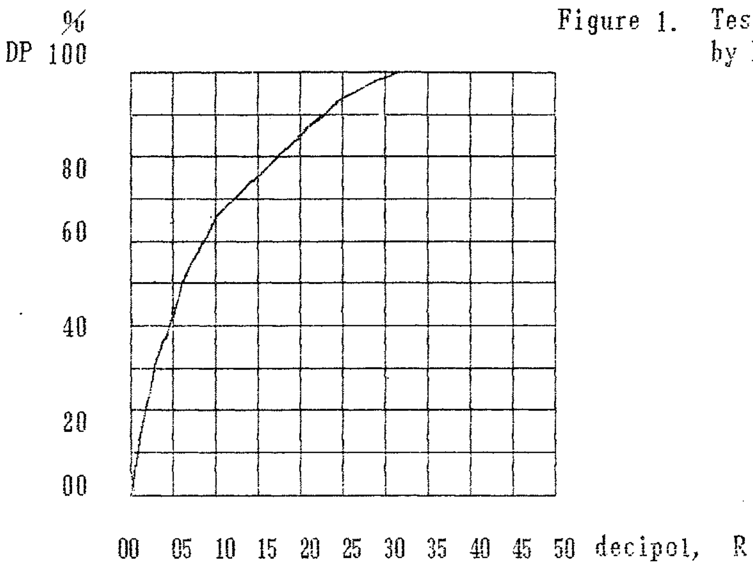

Figure 1. Test curve for olfaction by P.O.Fanger's method

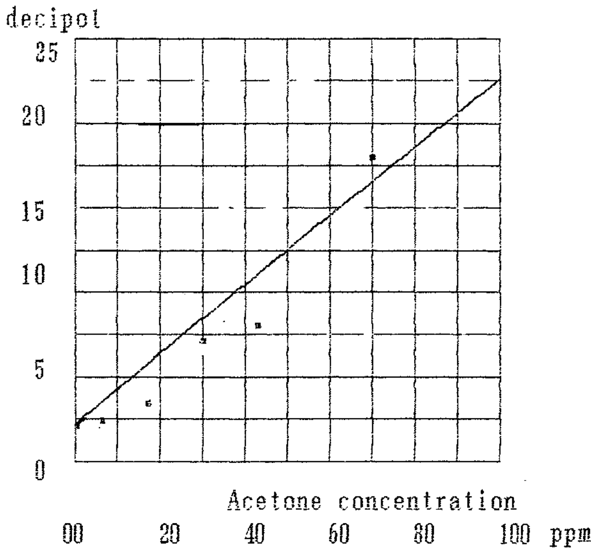

Figure 2. The equivalence of Decipol and acetone concentration ppm

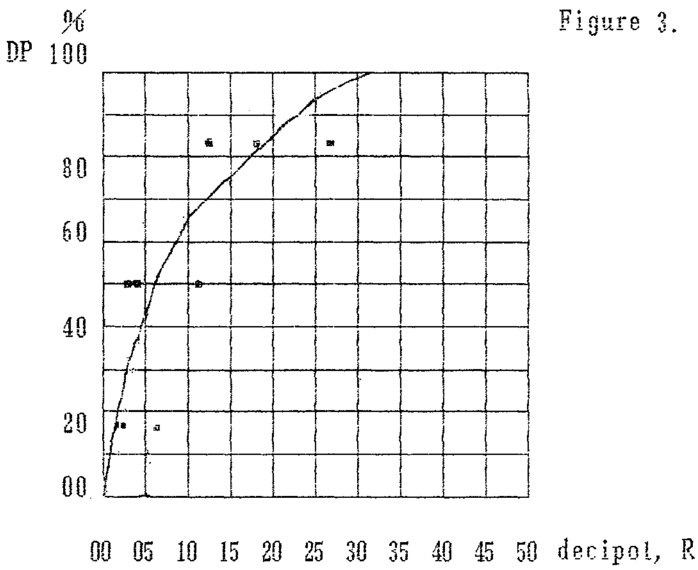

Figure 3. Test curve for olfaction by the German VDI method

2.3 Theoretical method

This is the key part. in this paper, so that. in this part the process of performing mathmatical calculation need in detail

3 Developing the olfactory formula

3.1 At first cut and try

let us put $f(p)=p$, then the expression (I) can be written as separated variables expression as

$$dp/p = kdR/R^{m} \qquad (1)$$

which has The integration as follows

$$\ln p = -k/(m-1)R^{m-1}+C \qquad (2)$$

where C is a integral arbitrary constant. To solve for p we have

$$p = e^{-k/(m-1)R^{m-1}+C} \qquad (3)$$

where k, m. and C to be determined by three points on the tested curve.

Let us put $m-1>0$, then $R\to 0$, $P\to 0$ [this point is on the Fanger tested curve]; as $R\to\infty$, the $P=100\%$. Under these conditions, the expression (2) can change as follows

$$p = 100\, e^{-k/(m-1)R^{m-1}} \qquad (4)$$

where $C=\ln 100=4.60517$. As take other two points on the Fanger curve as $R=20$, $P=84.61$; $R=15$, $P=75.38$. Substituting these values into equation (4) respectively, we get two simultaneous equations for k and m as follows,

$$\ln 84.61 = \ln 100 - k/(m-1)20^{m-1}$$

and $$\ln 75.38 = \ln 100 - k/(m-1)15^{m-1}$$

which can be simplifying as

$$k/(m-1)20^{m-1} = 0.167117723 \qquad (5.1)$$

and $$k/(m-1)15^{m-1} = 0.282628198 \qquad (5.2)$$

In the last two equations as the second one is divided by the first one, we have in which can be solved by m as

$$m=1+\ln(1.6911925)/\ln(20/15)=2.826439503 \qquad (6)$$

To substitute m in expression (6) into expression (5.1) we get

$$k=0.167117723\,(m-1)20^{m-1}=72.591 \qquad (7)$$

The solution is

$$P=100\, e^{-39.745\, R^{-1.82649503}} \qquad (8)$$

where $C=\ln 100=4.60517$.

The calculated results list in 4-th column in Table 1, which though differs from Fanger's curve; but it nears the state of three right tested points by VDI method, as shown in Figure 4. This curve and Fanger's curve have two common points. But on all other points the calculated points are smaller than tested values. So, we will be cut and try to take reference points at the section with greater slope.

3.2 Cut and try again

As take other two points on the Fanger curve to try. such as $R=10$, $P=65.39$; $R=15$,

Table 1. Data comparison of Fanger PD to calculated PD

no	decipol values R	PD from Fanger's curve	PD by formula (8)	PD by formula (9)	PD by (16)	PD by formula (17)	PD by (16)
1	0	00.00	00.00	00.00	00.00	00.00	00.00
2	1	13	0.00	1.4	1.403	13	13.5
3	2	22	0.00	12.0	12.21	26.0	28.16
4	3	31	0.48	24.27	25,16	34.81	38,79
5	4	37	4.25	34.58	36,41	41.16	46.84
6	5	46.15	12.22	42.76	45.59	46.15	53.21
7	10	65.39	55.28	65.39	72.26	59,9	72.74
8	15	75.38	75.38	75.34	84.60	66.9	83.33
9	20	84.61	84.61	80.86	91.63	71.33	90.31
10	25	93.08	89.48	84.37	96.16	74.41	95.31
11	31.3	100	92.89	87.31	100.00	77.24	100
12	∞	100.00	100.00	100.00	100.00	100.00	100.00

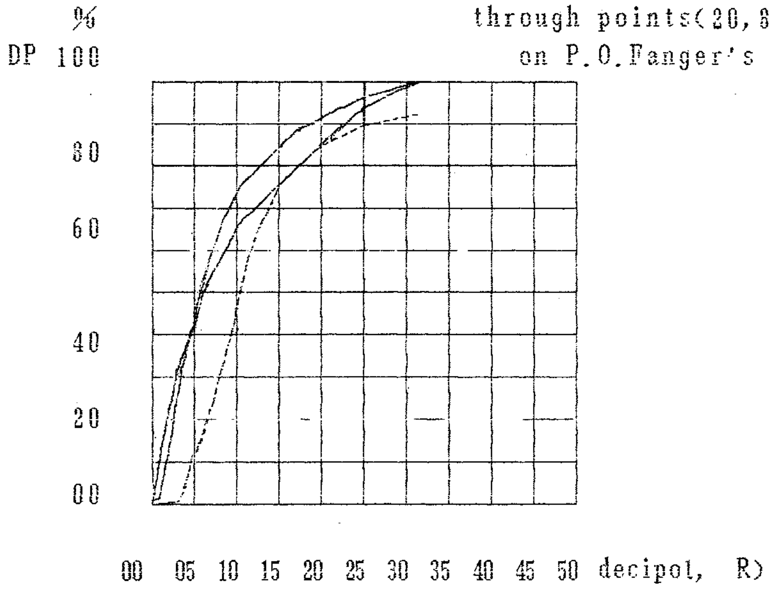

Figure 4. The broken curve is calulated, pass through points(20, 84.61);(15, 75.38) on P.O.Fanger's curve

P=75.38. Substituting these values into equation (4) respectively. we get two simultaneous equations for k and m as follows:

$$\ln 65.39 = \ln 100 - k/(m-1)10^{m-1}$$

and

$$\ln 75.38 = \ln 100 - k/(m-1)15^{m-1}$$

which can be simplifying as

$$k/(m-1)10^{m-1} = 0.424800844 \qquad (5.1')$$

and

$$k/(m-1)15^{m-1} = 0.282628198 \qquad (5.2')$$

As the second one is divided by the first one in the last two equations, we have

$$(15/10)^{m-1} = 1.503037728$$

hich can be solved by m as

$$m = 1 + \ln(1.503037728)/\ln(15/10) = 2.00499 \approx 2 \qquad (6')$$

To substitute m in expression (6') into expression (5.1') we get

$$k = 0.424800844(m-1)10^{m-1} \approx 4.248 \qquad (7')$$

The solution is

$$P = 100\, e^{-4.248 R^{-1}} \qquad (9)$$

From calculated results, it can be sees,, as the reference points influence the curve inclination as shown in Figure 4 and Table 1. The data at 4-th column are two co-points with Fanger's curve which are point (15, 75.38) and point (20, 84.61) where is located at the section of smaller slope of Fanger's curve ; similarly, the data are calculated by formula (9) at 5-th column are two co-points with Fanger's curve which are point (15, 75.38) and point (10, 65.93), where is located at the section of middle slope; again the data at 7-th column are two co-points with Fanger's curve which are point (5, 46.15) and point (1, 13). But the rate of selected function is changing still slowly. whichever that Pd value can not reaches 100% in finite value of R decipol. Unless R=∞. It is said, the function f(P)=P can not unsuitable, It requires further improving.

3.3 New function selection

let us take a fit function as f(P)=P(a+bP), which has partial fractions as

$$\frac{1}{P(a+bP)} = \frac{1}{aP} - \frac{b}{a(a+bP)} \qquad (10)$$

where a,b are constants to be determined to fit the tested curve.

Substitute the partial fractional function(10) into the differential equation (1), we have

$$dP/aP - b\,dP/a(a+bP) = k\,dR/R^m \qquad (11)$$

The integration is

$$\ln P - \ln[1+(b/a)P] = -ak/(m-1)R^{m-1} + aC \qquad (12)$$

or writting as

$$P/[1+(b/a)P] = [100\, e^{-k/(m-1)R^{m-1}}]^a \qquad (13)$$

Put factor in right square brackets be the symbol □ present 8 solution of formula (8) or (9), then we get

$$P/[1+(b/a)P] = \square^a \qquad (14)$$

from the last equation to solve for P as

$$P = \frac{\square^a}{1-(b/a)\square^a} \qquad (15)$$

where as put a=1, b/a=Ω. then

$$P = \frac{\square}{1-\Omega\square} \qquad (16)$$

According to Fanger's condition, 31.3 decipol, PD=100(%); to calculate □ by formula (9), on this case PD=87.32(%). Fro3 formula (16) we can determine number $\Omega = 1.453441759 \times 10^{-3}$. Calculated results by formula (16) list in last column of Table 1.

From the data in the Table 1, we can he seen that as the reference points in the middle of the curve, the difference is larger nearing two ends. So that we must take the reference points at the end near zero, due to it is very sensitive, and the influence is very small due to the correct at another end. Let us take points ii, 13) and (5, 46), then at first point we have $0.13 = e^{-k}$, $k = -2.04022082$; at second we have $0.46 = e^{-k5^n}$, $n = 0.600196876$. PD function is

$$P = 100\ e^{-2.04022082/R^{0.600196876}} \qquad (17)$$

A series data of □ are calculated by the formula (17) list in Table 1 also. On this case DP value merely 77.24 corresponds to 31.3 decipol which corresponds DP=100 on Fanger's curve. So the Ω in expression (16) has determined as

$$\Omega = (100 - 77.24)/100/77.24$$
$$= 2.946659762 \times 10^{-3}$$

According to expression (16) we can calculate the DP data list in the last column in Table 1. The corresponding curve as shown in Figure 5. It can be seen, this curve can be epitomized the regularity in Fanger's olf method and German VDI method.

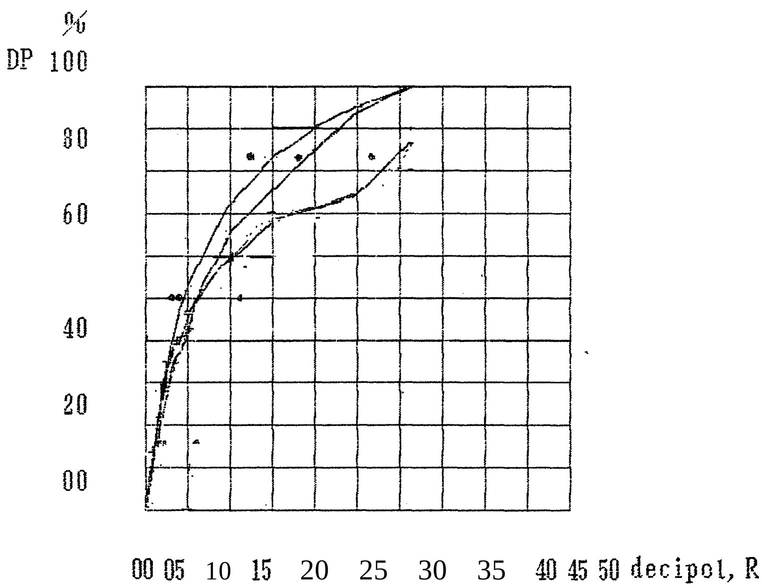

Figure 5. the theoretical curve drawn by formula derived

4 Conclusions

The coefficient function f(P) in the generalized Weber-Fechner law had been found, This function is a product of two factors. the inverse of which has two partial fractional functions. one factor make an usual exponential change and another factor modifying the exponential change with the human smell. It is shown. the theoretical formula is real reflection human that is sharp for low concentration of smeller and it is dull for high concentration. the theoretical curve is almost forming an outer envelope for all test data, which shows the human olfactory character to be sharp in low concentration smeller and dull under high concentration smeller. It can seen, This law is summarized from practice but it is higher than that practice.

The generalized Weber-Fechner law have been successfully found some function between the physical excitation and physiological sensation, such as, the room articulation function, the visual visibility function, the thermal comfort function and now the olfactory function. from one by one successful experiences the prediction can be redeclared, that the generalized Weber-Fechner law is a half universal formula from which can be found a sensational function to describe the relationship of a corresponding physical excitation, provided the tested curve has been work up.

5 Acknowledgement

The author have devoted himseif to the study on the generalized Weber-Fechner law since the year 1960. The author thanks the support of construction ministry from a to z. The Natioal Natural science foundation had powerfully support in a critical moment for abroad making international technical exchange. the leaders at all levels support this project in best. the author also thanks many peers to review and to give some good opinions.

THe author thanks the German Professor Karl A.J.Gertis very much for kind send to me the new information for German new achievement[4]. which recalls my original interest to apply the generalized Weber-Fechner law to olfactory problem.

Selection of a Contractor - Evaluation of Bids

Anna Seeger Meriaux
Bengt Hansson
Dept. of Construction Management, School of Civil Engineering, Lund University

Abstract
Factors other than price are being considered increasingly often during the procurement process. These other factors can include quality, competence, resources, recycling, longevity of materials and constructions, or the impact on the environment of the implementation. The tendering procedures of a great number of public works projects carried out in Sweden during the last few years have been studied. Special attention has been devoted to the evaluation of factors other than the price in relation to the choice of contractors. This project also aims to show how bids are evaluated in practice and, on the basis of this, suggest a bid evaluation model better suited to the requirements of the client. The aim of this paper is to describe some models that are commonly used to evaluate bids concerning tendering of public works.
Keywords: tender evaluation, evaluation models, contractor selection

The need for development in the construction sector

In order to create and maintain a construction sector that can meet the requirements for increased effectiveness, the construction sector and the client in particular must devote more resources to research and development. The construction sector in Sweden and the rest of Europe are marked by a slow rate of development, especially in comparison to the fixed industries. Many of those involved in the branch hold the view that the reason for the present slow rate of development is that the forms of procurement that are usually used discourage innovation. [1] In order to create larger dealing freedom, new forms of procurement must be developed.

Construction work clients are striving for forms of procurement that provide a secure process, as well as a long-term innovative process. The choice of form of procurement and the choice of method for evaluating the bids affect the pre-requisites for reaching this goal (see *Fig. 1).*

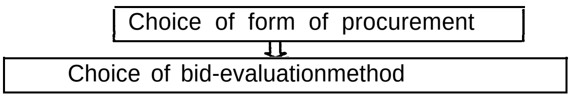

Figure 1 *The choice of form of procurement affects the choice of bid-evaluation method.*

One effect of the increased desire of contractors to develop new, more effective solutions will probably be bids with larger variations in price and size than is usual today. All bids must, however, be able to be compared and evaluated in a similar way. At the same time, the evaluation methods ought to reward good suggestions with innovative content.

The more freedom a contractor is given, the more possibilities there is of finding solutions that fulfil the client's requirement of limited use of resources. However, the more freedom they are given, the more factors must be taken into account when evaluating the bids (see *Figure 2).*

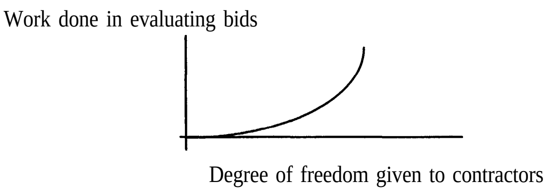

Figure *2 Relationship between the extent of evaluation work and the degree of freedom given to contractors*

The factors may have to do with the environment, quality, safety, etc. Evaluation of these factors is accomplished with the help of evaluation models that include price factors.

In addition to being a tool for selection, the evaluation models serve to direct contractors' bid presentations toward the project goals. Another reason for using evaluation models is that the client, in creating a model, gains a better knowledge of what is important in construction.[2,3,4]

Objective and Limitations

The main objective of the research project is to contribute to the development of a construction sector that is more inclined toward innovation. The aim of this paper is to

[4] **Totalentreprenad, 1981**

review models for evaluating bids and describe currently occurring bid evaluation methods for road-building procurement in Sweden.

The research project is selective to include procurement of road projects outside of the cities.

Scientific Method

An evaluation model must help ensure that the client's wishes are fulfilled. Figure 3 shows the various factors that contribute to an evaluation model.

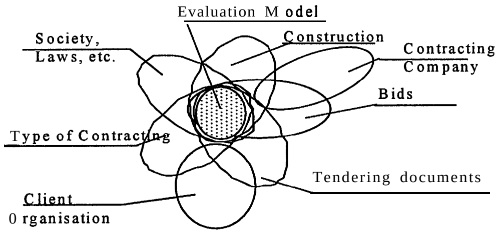

***Figure** 3 Evaluation model for bids, seen as a system composed of several sub-systems.*

Based on this reasoning, it is appropriate to choose the way of viewing the system as the starting point for the research project.

Research work can be regarded as a process of finding things out. The knowledge that is generated forms the basis for the next phase. The method in the first phase has involved studying the literature and empirical research of various models used in the reference project.

A great many theories exist about how to achieve the best results in evaluation of bids. This paper deals with the structure and description of some general theoretical principles, including various evaluation methods and how evaluation models are constructed, as well as the most common evaluation models used by the Swedish National Road Administration.

After going through the literature, it can be stated that there are shortcomings in the theories regarding the effect of the evaluation method on the end result for different forms of procurement and types of project. Moreover, there is no analysis of how the methods and models that are used affect the propensity for innovation.

Various Selection Principles for Choosing a Bid

The following is the principal system for choosing a bid in procurement situations:

Pre-qualification		
lowest price	Price evaluated	Price set by the Client
Verification of minimum requirements	Verification of minimum requirements	Verification of minimum requirements
	Evaluation of soft parameters	Evaluation of soft parameters

***Figure** 4 Principal alternatives for choosing a bid.*

As shown by the diagram, several of the principles can occur together. Above all, there are almost always some sort of minimum requirements. Then there are methods that are more or less mixtures of these. For example, after pre-qualification, the point system can be used for soft parameters and pricing.

Pre-qualification involves evaluating various aspects of the bidding company's performance. A pre-qualified contractor must be capable of carrying out the planned project as the client wishes. The aim of pre-qualification is mainly to make it possible to select the contractors who will be asked to take part in a procurement process.

Choice of contractor based on lowest price: First it is verified that the bids contain everything that is asked for in the invitation to tender. The bids often contain conscious deviations (reservations) from the invitation to tender. For the sake of price comparison, the evaluators must know what it would cost to remove these reservations. The evaluators can either request this information from the contractor or make an estimate themselves.

Verification of minimum requirements: When using this method, it must be verified that the so-called soft parameters fulfil certain minimum standards; they are then given a mark of 'pass' or 'does not pass.'

Choice of contractor based on evaluation of soft parameters*: The parameters are given different values, depending on how well they fulfil the client's requirements. They can be assigned different importance or weight in relation to each other, based on what type of project it is. The parameters are added up, yielding a total sum that indicates to the client which bid to choose.

Choice of contractor based on quality with set price: When a procurement is for a job in which the construction company has the main responsibility for the project, it is possible to set a maximum price for the building and then evaluate only the qualitative parameters of the bid.[5] [6]

Establishing an Evaluation Model

When it has been decided that the bids will be evaluated according to different parameters, an evaluation model is then established. The client begins by deciding which parameters will be included in the model. After this is established, how the parameters are to be evaluated must be defined. Usually this involves giving each parameter points on a scale from 1 to 5 or 1 to 10. The easier it is to evaluate a parameter, the greater the scale that may be assigned to that parameter. A scale of 1 to 10 may sometimes be seen as too large a spectrum for obtaining a correct evaluation every time. However, a more limited scale may cause information to be lost unnecessarily. It must also be observed that the distinctness of the rankings decreases with a more limited scale.

Difficulties may arise when the criteria must be evaluated, since some factors are not directly measurable. Hard parameters such as price pose no problem in this respect, as variations in price can be directly correlated with a point system. The value of a soft parameter, however, is often impossible to measure directly, and it is therefore significantly more difficult to assign it points. Methods must be found of relating the qualities of the parameter to some sort of point scale. Price parameters must be assigned points within the same system as the soft parameters in order to allow comparative weighting.

After the point scale is established, the relative importance of the different factors is defined. Weights are numbers that represent the absolute or relative importance in the total evaluation. Weighting must form the basis for a comparison of the different factors so that total values can be found for the various bids. Weighting can be assigned to parameters chosen for the evaluation model in several different ways. One method is to give each factor a monetary value. These values are totalled and the weight of the factors is proportional to their monetary value.

---

* **Soft parameters are all evaluated aspects that are separate from price/expenses.**

[5] **Byggindustrin, 1968**

[6] **Pernu Pirjo, 1997**

Another alternative is to weight the parameters by comparing them all with each other and deciding for each comparison which parameter is most important.[7] [8]

Yet another weighting system involves comparing each soft parameter to the cost parameter. The increase in cost that keeps the total value of the bid the same when a certain soft parameter is raised from the least possible to the highest possible level indicates the weight for that parameter.[9]

Comparative weighting of factors can be accomplished by different methods that do not necessarily all yield the same results. The easiest way is, of course, to assign the same weight to all the parameters. Then they can be totalled as is *(straight comparison)*, and the contractor with the highest total should be chosen.

The most common way of comparing parameters with different weights is to add up the products of each parameter's value and weight *(weighted comparison).*

Dividing each product by the maximum points possible for the parameter removes the significance of the differences in value scales between parameters *(corrected weighted comparison).* Then the focus is on how large a portion of the total value the parameter occupies in the given bid.

This reasoning requires that all parameters are independent of each other. In reality, it is highly unlikely that the parameters would not relate to each other in various formations. The theoretical way of solving this problem is to form a new parameter from the overlap between two parameters. It can, however, be a question of a large number of factors and the ones that are important to the project must be isolated.

Sensitivity Analysis

Before beginning to use the evaluation model, a sensitivity test must be performed, including a critical examination of the reliability of different types of evaluation. The analysis should answer the following":

- Which uncertainties and variations must be taken into account when assigning weight and points?
- How do such uncertainties affect the result of the evaluation, i.e. the rankings?
- How large a change can one make in the given weighting system before it affects the results, i.e. the bid rankings?

The client must be especially conscious of the fact that assigning points to soft parameters is in many cases rife with risk of subjectivity, randomness and mistakes in measurement.

The evaluation models of the Swedish National Road Administration

Representative evaluation models used by the Swedish National Road Administration between January 1994 and June 1996 have been studied. The models are continuously under development, but several basic principles can be discerned.

Just half of the Road Administration's regions make use of evaluation models for new procurement investments. Procurement of up-keep and maintenance projects in all regions is carried out using evaluation models produced centrally at the Road Administration. The Swedish National Road Administration uses three different criteria for selecting bids:

- Evaluation of soft parameters and price according to an evaluation model,
- Verification and evaluation of established minimum requirements,
- Lowest price.

---

[7] Janson Patric, 1970
[8] Andresen Inger, 1997
[9] Ericson Gösta, 1971
[10] Ericson Gösta, 1971

The evaluation models that exist all arrive at their evaluation based on both soft parameters and price. Evaluation models contain criteria for both the contractor and aspects of the project itself. The most common parameters are:

- **The contractor's quality-control system.**
- **The bidder's ability to complete the task.** (The client considers the size of the bidding company, physically and economically)
- **Previous projects.** (For example: what was the quality level, how was the traffic situation taken care of, did the contractor present unmotivated demands or have a tendency to make things difficult? In certain cases it is worth points if the client has previous experience working with the contractor.)
- **Partners offered** (experience, qualifications, number of years in the business, etc.)
- **Contractor's models, methods for procurement of sub-contractors**
- **Production time** (time when the project will be opened to traffic, identification and minimisation of traffic disruptions)
- **Production methods,** as well as alternative course of action in case of any extreme circumstances. (Points can also be awarded to contractors that demonstrate that they have paid the most possible attention to the environment through environmentally-friendly methods and equipment and environmentally-safe storage and material handling.)
- **Aesthetics** (For projects that include bridge-building, aesthetics will be judged based on the opinion of a special committee.)
- **Secondary offers** (In some few cases points will be awarded if the bid is accompanied by secondary offers that make it possible for the client to reduce costs).

The Road Administration's evaluation models take into account 5-6 soft parameters with 3-4 sub-parameters each. The weight of the main parameters varies between 5% and 20%. The bid total is heavily weighted (40–60%) in all the models.

Points are usually awarded with the help of guides that specify which information the bid must include in order to receive certain points. In most cases, a scale of 0 to 4 or 5 is used for every sub-parameter.

The amount of points in the bid total (if it is given points) is decided based on how much the bid total deviates from the lowest bid. The remaining bids receive points depending on how many percent higher they are than the lowest bid, on a linear scale (see Figure 5). If the contractor requires an advance on the payment, the bid total is usually increased according to a nationally established interest rate. For larger contracts a longevity factor is often also evaluated and assigned points.

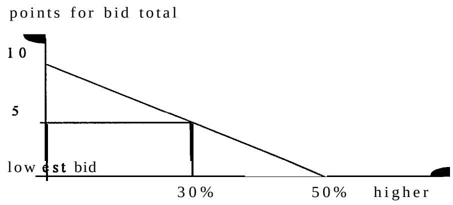

Figure 5. Example of how the bid total can be assignedpoints.

The points are worked into a total sum by dividing the total points of each parameter by the maximum points for the main parameter and multiplying by the weight. Lastly, these points are added to figure out the *(corrected weighted comparison).*

New Investment

The most common type of evaluation model in use in procurement of new investments is a function of several different parameters, P:

$$\text{Model} = F(P1, P2, \ldots Pn)$$

The model shows how the values work out to a points total, T_p, for each bid; this forms a basis for decision-making when a bid must be chosen. The bid that has the highest T_p will be accepted.*

$$T_p = \Sigma_{j=1}^{j=n} P_j \ , \text{ where } P_j = (\Sigma_{j=1}^{j=n} a_{ij} \ * \ w_j)/ \Sigma_{j=1}^{j=n} a_{ijmax}$$

w_j is the weight for parameter j and $\Sigma_{j=1}^{j=n} w_j = 1$.

a_{ij} represents for certain P several sub-parameters (the target for the contractors to aim at). a_{ij}/a_{ijmax} is then a value of how well the target for parameter *ij* is fulfilled. For some values of P (the parameter for evaluating aesthetics, environmental consequences, etc.) a is a mark given by a special evaluation group, such as an aesthetics committee, for example.

For so-called hard parameters (for example investment expenses, longevity expenses or interest expenses for advance payments) a is a point that has a direct relationship to the monetary value.

As shown in the formula above, every P is divided by the maximum point total that the parameters can reach, a_{ijmax}. This provides a degree of goal achievement and means, practically speaking, that the effect on the total sum that would have originated in the parameter's point range is eliminated.

This model allows the parameters, P, that the client regards as most important to have a stronger effect on the ranking than other, less important parameters (see *Example 5).*

Example 5 Assuming that there are two bids, A and B, the evaluation model appears as follows:

The bid was awarded the following points:

			A	B
1.	Quality	O-5 pts weight: 35%	3	1
2.	Time	O-5 pts weight: 10%	1	3
3.	Price	O-8 pts weight: 55%	4	4

Both bids have received 8 points in all but A has the highest total points: A: 3*0.35+1*0.10+4*0.55=3.3
B 1*0.35+3*0.10+4*0.55=2.85

There are other types of models used less often. In one region a model has been developed for procurement of new investment objects from general contractors in which the wishes of the customer are taken into account in a more pronounced way. In this model points are also given if the bids include secondary offers that are better than the client's wishes. This model does not include weighting the parameters; instead, the bids are ranked according to their point totals.

Another type of model multiplies the points for respective parameters by their weights, and these products are added up to calculate the total value of the bid. The total value is then divided by the bid total, expressed in thousands of Swedish crowns. The quotients are then finally multiplied by 1000 *(see Example 6).*

Example 6.

Assuming that there are two bids, A and B, which received points as shown in the table below.

	Total pts. Bid A	Total pts. Bid B
Competence	5	4
Quality	6	8
Organisation	3	2
Traffic	8	6
Bid	500 000	450 000

The total points for both bids are calculated:
A: ((5*0.35+6*0.35+3*0.15+8*0.15) / 500)*1000= 9.9
B: ((4*0.35+8*0.35+2*0.15+6*0.15) / 450)*1000 =ll.l

* Under the condition that the 'most economical& advantageous bid' must be chosen.

An attempt to provide the contractors with a little more space was made in the evaluation model and calculation methods for the points of the bid total. Normally the lowest bid alone gets to receive maximum points for this parameter. Instead, the lowest bid, along with all other bids up to 5% higher, received the maximum points, raising the significance of the soft parameters.

The Up-Keep and Maintenance Model

Since 1996, up-keep and maintenance procurements have been made with the help of an evaluation model that verifies how well certain requirements are met. All requirements had to be fulfilled to a certain degree and the bids could receive extra points for parameters that were especially well fulfilled.

If the company fulfils some of the different parameters' surplus requirements, a percentile deduction is made from the bid at the bid-total level. In this way, meeting the requirements especially well can have an effect on the ranking of the bid totals.

The invitations to tender ask for bids in two parts: one with the bid total and the other including additional offers and suggestions. The parts containing the additional offers and suggestions are opened first. The reason for opening the bid totals afterwards is to avoid the risk of subjective evaluations affected by the prices.

Invitations to Tender

In all the cases studied, it was specified that the bids be evaluated in a professional way, and that the most economically advantageous bid should be selected, which means that more than just the price of the bid must play a significant role in the process.

In general, it can be said of the descriptions in the invitation to tender about how the bid evaluations will be carried out that they are insufficient. When an evaluation model is used, it is not always provided with the invitation to tender.

In the administrative introduction to the invitation to tender, under the heading 'Form and Content of the Bid,' it is specified which information and documents must be enclosed with the bid. The parameters listed under the heading 'Basis of Evaluation' can not always be taken solely on the basis of the 'Form and Content' section. It is left up to the contractors themselves to decide which documents ought to be enclosed with the bid

An empirical study of how the evaluation models are utilised in practice has been made. Some of the conclusions that can be drawn from it are that the total value of a bid can vary based solely upon which documentation has been enclosed with the bid, and that the better the client knows the contractor, the less the significance of the documentation.

Conclusion/Continuing Research

Alternative methods for evaluating bids have been reviewed in brief. To reach the overall goal of a more innovative construction sector, the conditions of procurement must be altered. The invitation to tender must be designed to show contractors clearly that innovative input is expected and will be rewarded. Evaluation models must be created that allow this rewarding to occur.

The evaluation system should also function in such a way that there is documented follow-up of the project results, which can then be compared with evaluation models and procurement data (see Figure 6).

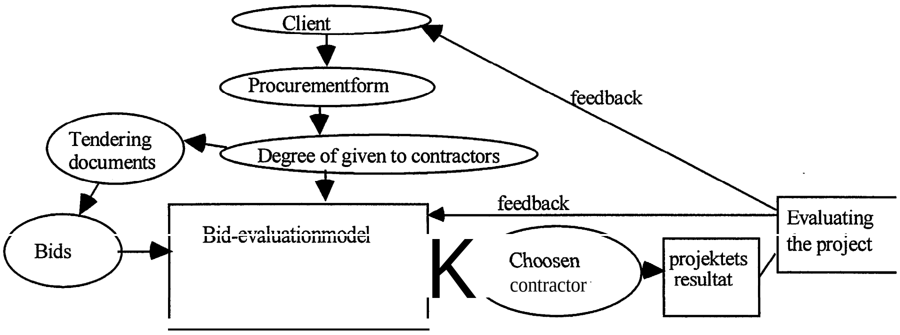

Figure 6. System for follow-up and experience-based feedback on project results.

Experience-based feedback will help in part when the client must choose principles for evaluation. It will also act as the basis for the creation of a new evaluation model or the improvement of an existing one.

In the next stage of the research project, selected methods for bid evaluation will be analysed and one or several model methods will be developed that are suitable for bid evaluation in contracting that encourages innovation on the part of those involved in the construction process. During the analysis, special attention will be paid to the effect of evaluation methods on innovative contributions. More concretely, one of the questions will be how much the evaluation method can encourage innovation from those involved.

As a basis for development of evaluation models, an empirical (quantitative) study will be undertaken and several interviews (qualitative) will be conducted. The analysis of current evaluation methods will also form the basis for suggestions for evaluation models that will work for the procurement of innovative projects. The suggested models for bid evaluation in innovation-oriented procurement will be duly tested in some actual construction projects, thereby testing the hypotheses

Health effects of installing a new ventilation system in school buildings

G. Smedje, D. Norbäck, C. Edling,
Dpt of Occupational and Environmental Medicine, University Hospital, Uppsala, Sweden

Abstract

Apart from the home, school is the most important indoor environment for children aged 6-16 and there is a growing concern about the impact on health of the school environment. It has been shown that the air exchange rate often is low, but there are few studies on the relation between health symptoms and school ventilation. We have studied changes in the prevalence of symptoms compatible with the "Sick building syndrome" among school pupils, and related this to the installantion of a new ventilation system in school.

Pupils in 39 randomly selected schools participated in the study. Recording of symptoms was made by means of a self-administered questionnaire that was answered twice by 1476 pupils aged 7- 16; in 1993 and again in 1995. Information on the installation of a new ventilation system in school between 1993 and 1995 was obtained by inspections by the researchers and information from the caretakers of the buildings. Both years exposure measurements were also performed in the schools. The changes between 1993 and 1995 in the prevalence of symptoms in pupils attending schools that got, respectively did not get, a new ventilation system, was analysed.

The classrooms that had got a new ventilation system had in 1995 a higher air exchange rate and the relative humidity, concentration of carbon dioxide and formaldehyde was lower, compared to the other classrooms. Symptoms compatible with the Sick building syndrome in the pupils had increased after the two years, but pupils attending schools with a new ventilation system reported less nasal and general symptoms, and more skin symptoms compared to the other pupils.

Thus, installing a new ventilation system in school could reduce both exposure and SBS symptoms in the pupils, but the effect may vary for the different groups of symptoms.

Keywords: schools, pupils, Sick building syndrome, ventilation system, exposures

1 Introduction

Poor indoor air quality in non-industrial buildings has been supposed to cause different health problems, among them the Sick building syndrome (SBS) which involves various non-specific symptoms such as eye, skin and upper airway irritation, headache and fatigue [1]. The role of building ventilation for SBS has been investigated in several studies, mainly among office workers. Godish has recently reviewed this literature and concludes that the studies have reported mixed results, but that there is limited evidence to suggest that an outdoor air flow up to 10 l/s per person may be effective in reducing the prevalence of sick building symptoms and occupant dissatisfaction with air quality [2]. Children are likely to be affected at a lower concentration of various pollutants, thus studies on SBS among children should be helpful in understanding the phenomenom, but there are few such investigations.

Apart from the home, school is the most important indoor environment for children aged 6-16 and there is a growing concern about the impact on health of the school environment. Several studies have been published showing deficiencies in the indoor air quality in schools. The concentrations of dust and airborne and dustbound microorganisms and pet dander are relatively high [3-5]. The air exchange rate is low, the concentration of carbon dioxide (CO_2) is high and the ventilation standards are often not fulfilled [6-8]. The possible impact on the health of the pupils of improving the school ventilation should be an important aspect, but there are, to our knowledge, few studies on this subject. However, studies on SBS among school employees have not found any relation to a low air exchange rate as expressed by a high concentration of CO2 [8, 9]. These studies are typically cross-sectional and there are few longitudinal studies relating SBS to changes in the ventilation parameters.

In the Swedish School Environment Project we have undertaken a number of studies on asthmatic symptoms and SBS among school personnel and pupils and have related these to the school environment. In this paper we present results concerning the effect of a new ventilation system in the school building on exposure factors and symptoms compatible with the Sick building syndrome among school pupils.

2 Material and methods

2.1 The study population

In 1992, we randomly selected 39 primary and secondary schools in the county of Uppsala in mid Sweden. The schools varied in respect to factors such as age, construction and size. For each primary school, 1 class in the 1st and 4th form, respectively, were randomly chosen. Since the number of secondary schools was lower, 3 classes in the 7th form were randomly chosen, except for 1 school where there were only 2 classes in this form. In total, 615 pupils in the 1 st form (being approximately 7 years old), 657 pupils in the 4th form (being approximately 10 years old) and 762 pupils in the 7 th form (being approximately 13 years old) were invited to participate in the study.

2.2 Information from the pupils

Recording of symptoms was made by means of a standardized self-administered questionnaire that was mailed to the home adress of the puils in January-February 1993. To those who answered 1993 and who were still attending the same school, the questionnaire was sent again two years later, in december 1994-january 1995.

The questionnaire requested information on diseases and present symptoms and on domestic exposure. There were 16 questions on symptoms compatible with the Sick building syndrome. These symptoms were grouped into symptoms from the skin (facial itching, facial rash, itching on the hands, rashes on the hands, and eczema), nasal (nasal catarrah, and blocked up nose), throat (dryness in the throat, sore throat, and irritative cough), and eyes (eye irritation and swollen eylids), as well as some general symptoms (headache, abnormal tiredness, sensation of getting a cold, and nausea). These questions asked if the pupil had experienced the symptom during the past 3 months "no, never", "yes, sometimes (I -3 times/month)", "yes, often (1-4 times/month) or "yes, daily". For each symptom group the prevalence of at least weekly symptoms was calculated for both years, as well as the number of symtomatic days/month and the number of pupils reporting more, respectively fewer, symptomatic days 1995 compared to 1993.

The questionnaire also contained some questions on other symptoms like asthma and allergies, the composition of the family, smoking habits and domestic exposures such as environmental tobacco smoke and signs of dampness in the home. There were also some questions about the psychosocial environment at school.

2.3 Assessment of exposure

Exposure measurements were performed in the schools during spring 1993 and again in the winter of 1995. In each school we chose 2-5 classrooms. In primary schools each class usually had its own classroom, and we thus chose the classroom of the classes that had got the questionnaire. In secondary schools, the pupils attended different classrooms depending on the subject, and we chose classrooms so that the diffrent school buildings were represented. Some of the classes changed classrooms between the two years, thus it was not always the same rooms that were investigated both years. In 1993 a total of 98 classrooms was investigated, and in 1995 10 1. Of these, 5 1 were investigated both years.

We inspected the buildings and noted details of their construction including type of ventilation system. We measured the air exchange rate with a tracer gas decay method. Based on the air exchange rate and the room volume, the outdoor air flow was calculated. Information on the installation of a new ventilation system between 1993 and 1995 was obtained from the caretakers of the buildings, as well as on other building measures undertaken in the school, like repainting or new floor covering. In each classroom we measured the temperature, relative humidity, and the levels of C02, respirable dust, formaldehyde, other volatile organic compounds (VOC), VOC produced by microorganisms (MVOC), moulds and bacteria. The methods have been described elsewhere [7].

2.4 Statistical methods

MC Nemar's test was used to analyse possible differences in the prevalence of the symptoms between the two years. Differences between measured exposure in the classrooms that got, respectively did not get, a new ventilation system were analysed using the Mann-Whitney U test.

Analysis of the relationships between the symptom variables, other questionnaire data and the occurrence of a new ventilation system were undertaken with multivariate methods. Multiple logistic regression analysis was performed in several steps using the SPIDA statistical package [10]. Each outcome variable was analysed separately. A crude analysis was made including only the outcome variable and the occurrence of a new ventilation system. The different outcome variables were then tested against other questionnaire data one at a time and some personal factors were found to be important confounders. Separate analyses were undertaken controlling for these confounders, and for other building measures that had been undertaken at the same time as the installation of the new ventilation system.

In all the statistical analyses, two tailed tests and a significance level of 5 % were used.

3 Results

3.1 Information from the pupils

Out of the 1879 selected pupils that were attending the same school during the whole period, 1476 (79 %) answered the questionnaire both years. The non-responders were more freauent among the secondary school pupils compared to the primary school pupils (response rate 76 % and 8 1 %, respectively).

The answers to the different questions on SBS symptoms are given in table 1, presenting the prevalence 1993 and 1995 of at least one weekly symptom. For nasal and general symptoms the increase of symptoms between the two years was statistically significant.

	1993	1995	p-value*
Eye symptoms	1.2%	2.0 %	**n s**†
Nasal symptoms	7.1 %	8.7 %	co.05
Throat symptoms	5.6 %	6.9 %	n s
Skin symptoms	**10.1 %**	**9.7 %**	n s
General symptoms	15.9 %	24.8 %	<0.001

* Differences in symptom prevalence between the years analysed by McNemar´s test.

† Not significant.

‡ At least one weekly symptom during the past 3 months.

Table 1 Prevalence of SBS symptoms‡ in 1476 school pupils 1993 and 1995

Calculating the monthly number of symptomatic days showed that there was a significant increase of symptoms between the two years for all symptom groups. The percentage of pupils reporting more symptoms 1995 than 1993 was for symptoms from the eyes 7 %, nose 30 %, throat 27 %, and skin 12 %, while more general symptoms was reported by 41 %. Most of these differencies concerned a change of the rating from "no, never" to "yes, sometimes". For general and nasal symptoms, however, there was also changes toward experiencing these symptoms "yes, every week". There was also a considerable recovery from symptoms between the two years.

3.2 Exposures in the school buildings

The mean year of construction of the school buildings was 1960, with the oldest being built around the year 1900 and the newest in 1992. The majority (82 %) of the buildings had 1-2 storeys and 38 % had a basement. Most (63 %) were mainly built of stone.

In 1993, 77 % of the investigated classrooms did not fulfil the Swedish ventilation standard demanding a supply air flow of approximately 8 l/s per person and a concentration of CO_2 below 1 000 ppm [11]. The corresponding result for 1995 was 63 %. Out of the 98 classrooms that were investigated 1993, 11 were situated in buildings that later got a new ventilation system. Of these, 3 schools had natural ventilation only, 1 school had a mechanical exhaust air system, and 3 schools had mechanical supply and exhaust air system, with the air supplied according to the traditional dilution principle. In 1995, 101 classrooms were investigated, of which 12 had a new ventilation system. In all cases, the new system consisted of displacement ventilation with mechanical supply and exhaust air. Cooling or humidifying of the air was not applied.

Data on exposures 1993 and 1995 in classrooms with, respectively without, a new ventilation system are given in table 2

	1993			1995		
	later got new ventilation			new ventilation after -93		
	yes	no	p-value*	yes	no	p-value*
Air exchange rate (ach)	0.8	2.6	<0.01	5.0	2.8	<0.01
Outdoor air flow (L/s p)	1.9	5.8	<0.01	13.9	7.3	<0.001
Carbon dioxide (ppm)	1120	975	n s†	825	1050	<0.05
Room temperature (°C)	24.5	23.5	n s	21.5	22.0	n s
Relative humidity (%)	42	38	n s	31	35	<0.05

† n s=not significant

‡ Sum of volatile organic compounds < C_{13}.

§ Sum of 8 identified compounds.

Table 2 Exposures 1993 and 1995 in classrooms with, respectively without, a new ventilation system

In 1993, the air exchange rate was lower in the classrooms that later got a new ventilation system, and the concentration of most of the measured exposures was higher, although only for respirable dust the difference reached statistical significance. In 1995, after the installation of the new ventilation system, these buildings had a higher air exchange rate, and the relative humidity, and the concentration of CO_2 and formaldehyde were significantly lower than in the other buildings. However, there were no significant differences in the concentration of respirable dust, or airborne total or viable moulds and bacteria.

3.3 Relations between symptoms and the occurrence of a new ventilation system

In 1995, 143 of the pupils attended schools where a new ventilation system had been installed in the major part of the school since the investigation 1993, and 1 333 of the respondents did not attend such a school. There were no differences in 1993 between these two groups concerning the important personal factors related to SBS (age, gender, allergic diseases or the ratings of the psychosocial school environment).

Data on the relation between symptoms and the occurrence of a new ventilation system are given in table 3. Pupils attending schools with a new ventilation system reported more seldom an increase of nasal symptoms, and this relationship was significant both in the crude analysis and after controlling for personal factors (data not shown), and other building measures, respectively. After controlling for other building measures, pupils in the new ventilation schools less often reported an increase of general symptoms and less often a decrease of symptoms from the skin. In the crude analysis there was also a significant relation between attending a school with a new ventilation system and reporting less eye symptoms 1995 than 1993, but this relation was not found in the corrected analyses. Controlling for the personal factors did not cause any significant changes in the results (data not shown).

		Odds Ratio	(Confidence Interval)*	p-value
Eye symptoms,	increased	1.1	(0.5-2.1)	n s
	decreased	1.4	(0.6-3.4)	n s
Skin symptoms,	increased	1.2	(0.6-2.5)	n s
	decreased	0.3	(0.1-0.8)	<0.05
Nasal symptoms,	increased	0.3	(0.2-0.7)	<0.001
	decreased	0.9	(0.5-1.6)	n s
Throat symptoms,	increased	0.7	(0.4-1.2)	n s
	decreased	0.7	(0.4-1.3)	n s
General symptoms,	increased	0.5	(0.3-0.8)	<0.01
	decreased	1.5	(0.9-2.4)	n s

* Controlling for repainting, and new floor covering in the school.

† Analysed by logistic multiple regression.

Table 3 Significant relations between changes in symptoms between 1993 and 1995 and the occurence of a new ventilation system†

4 Discussion

4.1 Methodological aspects

There was a higher response rate among primary school children, compared to those in secondary school. Also, questionnaires on SBS have not not been used to this age group before, and there is a lack of "objective" clinical methods for these kind of symptoms to validate questionnaire data against. Hallén & Juto have, in adults, compared subjective ratings of nasal congestion with rhinostereometry and found a good agreement [12]. However, the possible bias between age groups or due to the method of collecting the symptom data, should not be systematicly different between those who attended the schools that got a new ventilation system and those in the other schools.

The tendency of reporting symptoms could be influenced by awareness of the school having, or not having, got a new ventilation system and expectations regarding its health effects. One could speculate that attending a school where remodelling is undertaken could affect the perception of the school environment, and the reporting of symptoms. If this was the case, such effects should be caused by different kinds of remodelling measures. But in this study we found that the other remedial activities that took place, in some schools, together with the installation of the new ventilation system, mainly repainting and new floor covering, were related to an increase of symptoms, and when controlling for these measures, the effects of the ventilation installation was strenghten.

4.2 Effects of a new ventilation system on measured exposure

In all the classrooms, the new ventilation system resulted in an increase of the air exchange rate, but the effects on airborne pollutants was not equally consistent. Gaseous pollutants, but not particles, tended to be lower in the classrooms with a new ventilation system. This is in accordance with studies from other indoor environments. Increasing the outdoor air flow in an office building reduced the concentration of formaldehyde, other VOC and CO_2 [13]. In three otherwise identical domestic houses, but with different ventilation systems, it was found that the concentration of particles and bacteria did not differ [14]. In a trial with different outdoor air flows in an operation theatre it was found that the number of persons present was the most important factor determining the particle concentration [15].

4.3 Relations between symptoms and the occurrence of a new ventilation system

Pupils attending schools with a new ventilation system reported less nasal and general symptoms, and more skin symptoms. Walinder et al [16] investigated personnel working in 12 of these schools with "objective" clinical methods and found that nasal congestion and higher levels of inflammatory cells in the airways, were more common among those working in schools with a poor air exchange rate, and less common among those working in schools with a displacement ventilation system. When it comes to the finding that skin symptoms seemed to be more impared among pupils attending the new ventilation schools, one could speculate that this could be due to the lower relative air humidity in these classrooms.

We do not know which were the qualities of the new ventilation system that were responsible for the results: the displacement principle, the increased flow, or the fact that the ducts, filters and diffusers (at least in some of the schools) were new and, hopingly, clean.

5 Conclusion

Installation of a new ventilation system in schools could reduce symptoms compatible with the Sick building syndrome in the pupils.

ISIAQ Guideline Moisture Control in Cold Climates

T. Follin
BARAB, Sweden

Abstract

ISIAQ (International Society of Indoor Air Quality and Climate) is producing Guidelines dealing with different aspects on Indoor Air Quality. The first one is a result from ISIAQ Task Force I called "Control of moisture problems affecting biological indoor air quality" (1) and was published at the conference Indoor Air '96 in Nagoya. The second one, on principles for investigation of IAQ complaints, not yet published, is a result of work done in ISIAQ Task Force II. At present'there are nine Task Forces working.

One of the Task Forces, "Moisture Control in Cold Climates", is just starting up. There was a Workshop, ISIAQ task group for microbial contaminant control, at the conference Healthy Buildings '97 in Washington in September -97. The workshop was chaired by Aino Nevalainen from the National Public Health Institute in Finland and Tom Follin from the consulting company BARAB in Sweden. The workshop was the real starting point for the work. At the same time another Task Force is working with the same kind of problems in Hot and Humid Climates.

The guidelines are meant to be practical handbooks to be used when solving existing IAQ problems and to avoid that kind of problems.
Key words: contamination, damages, guideline, moisture, SBS.

1. Introduction

Moisture is, at least in the Nordic countries, the main reason to bad indoor air quality. Moisture in the indoor air causes problems due to very low RH during winter time. The problem is to little moisture, -not to much! Lack of moisture in the air doesn't contaminate the air, it make it dry. Contamination of the air is mostly caused by degradation in/on building materials due to to much moisture. Not even among the scientists are those facts always quite clear.

ISIAQ (International Society of Indoor Air Quality and Climate) has organised two task groups in order to produce international guidelines dealing with the moisture related IAQ problems in cold climates and in hot and humid climates.

The guidelines are meant to be practical handbooks to be used when solving existing IAQ problems and to avoid that kind of problems.

2. The work

The Task Force, "Moisture Control in Cold Climates", is just starting up. There was a Workshop, ISIAQ task group for microbial contaminant control, at the conference Healthy Buildings '97 in Washington in September -97. The workshop was chaired by Aino Nevalainen from the National Public Health Institute in Finland and Tom Follin from the consulting company BARAB in Sweden. The workshop was the real starting point for the work. During the conference 15 persons, in different ways active in the IAQ field, have offered their assistance with writing contributions to the planned Guideline.

At present (Januari -98) 4 (!) have delivered some kind of material or promised to write parts of the guideline. A first draft structure of the guideline is sent to the contributors during Christmas -97.

Problems in houses due to moisture not always causes IAQ problems. As some kind of limitation is needed the guideline will concentrate on moisture problems affecting the indoor air.

3. The draft contents in ISIAQ Guideline: Moisture Control in Cold Climates.

4. The result

The resulting Guideline is going to be practical. It will contain the reasons to different kind of moisture related damages causing contaminations of the indoor air. Advices on measurings and possible cures or treatments will be given. Advices on how to avoid moisture problems will be given. Environmental issues are going to be observed. A booklet of about 80 pages is planned and will, if everything workes out, be published in 1,5 year.

Three green buildings from Venezuela: proposals for climate sensitive design

P. La Roche, F. Mustieles, M. Machado, I de Oteiza

Instituto de Investigaciones de la Facultad de Arquitectura, IFA, Universidad del Zulia. Maracaibo, Venezuela.

Abstract

Three green buildings designed to provide psychological, physical and social well being through improved comfort combined with lower energy consumption and less generation of wastes are explained.

The first case is the project "Habitar el Dispositivo" "T*o inhabit the device"* which was awarded a prize in an international competition in Tenerife in 1995 and in which the integration of bioclimatical and architectural concepts in a livable device is proposed; the second case is a bioclimatical house for Tamare, Venezuela, which incorporates design principles from traditional indigenous, colonial and oil company houses in the Maracaibo lake basin to generate a prototype adapted to contemporary urban Venezuelan problems; and the third case is a low cost variation of the second building.

Digital and analogical models of the first two prototypes have been built to analyze sunlight and shadow behavior and computer simulations permitted to predict thermal performance. Thermal satisfaction was 89.5% during typical summer and winter 24 hour periods for the Tenerife building; and in the Tamare house, assuming a higher comfort temperature, acceptable for summers in developing countries, we achieved 95% of satisfaction when the building is ventilated at night and closed during daytime. The third proposal has not been thermally evaluated yet.-

Some bioclimatic principles which are proposed for the summer of the Tenerife house and during the whole year of the Tamare house are: 1) minimization of radiation gains through windows and facades by solar protection, 2) minimization of conduction heat flow and thermal oscillations by-adequate positioning of insulation and mass and use of external light colors 3) control of air changes; and 4) bioclimatic landscaping. Some passive cooling techniques are: 1) comfort ventilation; 2) nocturnal convective cooling; and 3) direct evaporative cooling. During the winter of the Tenerife house, the summer principles will also perform adequately (insulation, mass, etc.) while protection from the cool winds and the passive heating technique, direct solar gain, is proposed.

Construction of the Tenerife and Tamare houses will begin in mid 1998 with financing from the Canarian and the European Economic Community for the Tenerife house, and PDV, the Venezuelan Oil Company, for the Tamare house. Financial assistance for the construction of the third prototype has not been secured yet. In all three cases thermal parameters and some indoor air quality parameters will be monitored after construction, to evaluate performance of these prototypes.

Keywords: Sustainable design, bioclimatical design, passive cooling and heating, housing

1 Introduction

Many bioclimatical buildings have been designed which seek to perform more efficiently. However, the performance of these is generally achieved by the addition of technological devices to a project, producing a work that is many times rejected by its dwellers, due to its high cost, complex appearance and even more complex utilization. In contrast to these proposals, we propose an integral relation between architecture and bioclimatism making these devices form part of man's space.

2 To inhabit the device: a bioclimatical house for Tenerife, Spain.

2.1 Architectural principles

As a base principle for the reencounter between architecture and bioclimatism, we proposed "to inhabit the bioclimatical devices", this is, to make them form part of man's space. Thus emerges, the inhabited triangular chimney, that directed towards the northeast, collects the wind and circulates it through indoor spaces.

As a second base principle, we proposed "to integrate the technological devices in an architecturized device". Thus appears the "Fortran" wall, called so because of its simple but operational technological devices which someway resemble old computer Fortran cards.

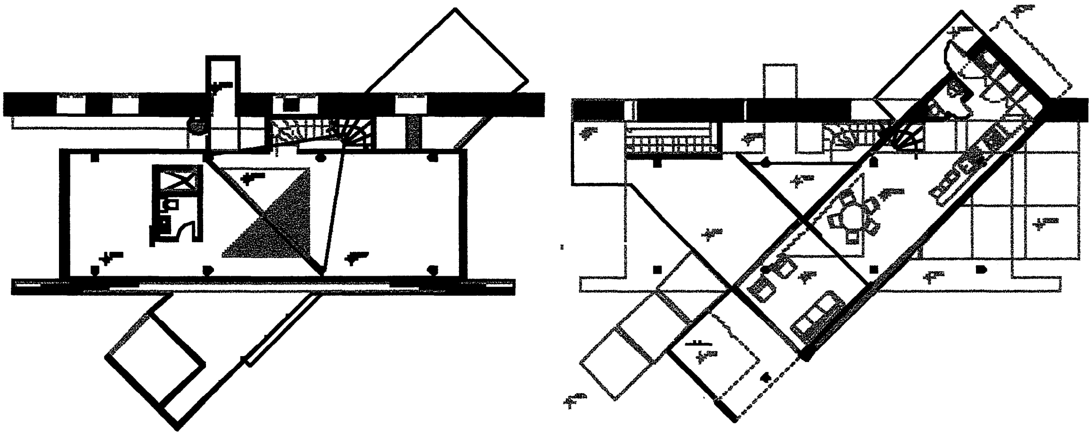

Fig 1 Plans of the Tenerife House

2.2 Bioclimatical techniques and passive systems

According to Givoni [1] bioclimatical techniques permit to reduce heat gains by conduction, radiation and convection through walls and windows in summer, and to reduce heat losses in winter. Passive cooling systems transfer incident energy to natural energetic deposits, or heat sinks, such as the air, the upper atmosphere, water and earth. Passive heating systems store and distribute solar energy without the need of complex controllers for its distribution.

Climate variables of southern Tenerife (Reina Sofia Airport) were analyzed using Fanger's and Givoni's method, in relation to the thermal comfort zone. Two situations were typified: winter, from November to May and summer, from June to September. In winter, night values are located in the passive warming zone, and towards noon, in the comfort zone. In summer, the values are located in the comfort zone during the night and in the comfort ventilation zone during most of the afternoon. Therefore, warming is required during the winter nights and cooling during the summer days; control of heat losses is also necessary in winter nights and control of heat gains in summer days. The building protects from the sun and opens to the fresh winds in summer, while in winter it opens to the sun and is closed to the cool winds.

2.2.1 Bioclimatical techniques

1. **Solar and eolic orientkion.** The direction of the building answers to the sun and to the wind. The top floor is oriented with its main shaft east-west, with openings to the south and protected in the other faces, answering to the solar direction. The ground floor is oriented 45 degrees in relation to the first floor answering to the dominant trade winds from the northeast. In the intersection of the two volumes and guided towards the northeast is located the triangular eolic chimney.
2. **Protection of openings** in **summer.** All the openings are adequately protected in summer. The transparent facade of the second floor has a rollable louvered mechanism permeable to the wind and impermeable to the light, that permits to regulate radiation to the dormitories, avoiding overheating.
3. **Mass and insulation as thermal regulators.** Indoor thermal mass and external insulation are used to store heat from the winter days and "cold" from the summer nights and to avoid heat gains in summer and losses in winter.
4. **Light external colors.** The external color of the facades is white, which reduces heat gain by conduction through walls and roofs, necessary in summer.
5. **Solar protection.** The overlapping of crossed volumes and the Fortran wall generate shaded areas, non-existent due to the lack of trees.
6. **Protection from cold winds.** The "Fortran" wall serves as thermal regulator of external conditions, protecting from the cold winds in winter but also has small windows that permit cross ventilation through spaces to generate comfort in the summer. The louvered windows can be also closed in the winter nights to protect the transparent facade and to reduce the coefficient of superficial conductance.

2.2.2 Passive cooling and heating systems

1. **Direct solar gain.** Energy gains in winter are by radiation through windows and then stored for night use.
2. **Convective night cooling.** Nocturnal ventilation cools internal mass of floors and walls during the night, reducing its surface temperature, helping to keep the building cool during daytime hours.
3. **Direct evaporative cooling.** The openings of the "Fortran" wall and of the eolic chimney have containers with water, to add moisture to incoming air and decrease air temperature.
4. **Comfort Ventilation.** High air speeds in the zone make it easy to introduce air into the house and extend the thermal comfort zone to the upper comfort values.

2.2.3 Renewable energy sources

Solar energy is proposed for water heating and photovoltaic cells to complement grid electricity and both located on the Fortran wall.

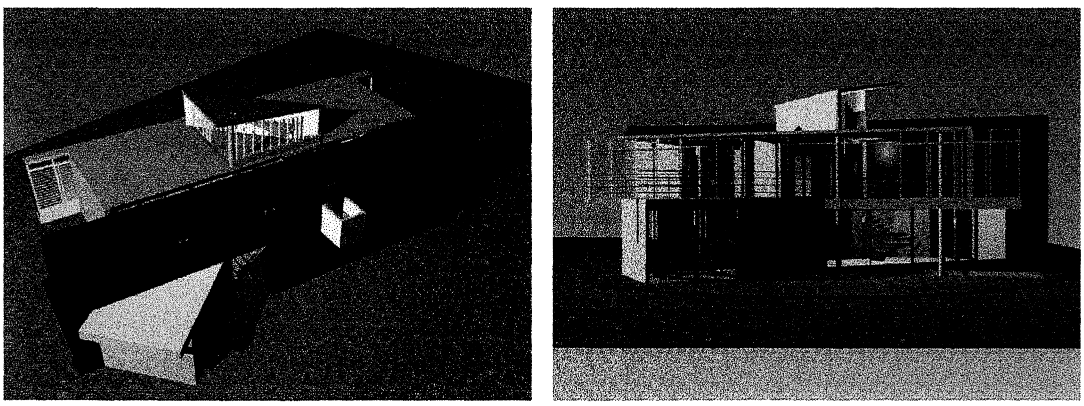

Fig 2 North and south views of the Tenerife House

2.3 Thermal evaluation of the proposal.

To determine the effectiveness of our proposal, the computer program for simulation of thermal behavior in dynamical regime CODYBA [2], was used. Data from the meteorological station was used to determine a typical summer day, July 15, and for a typical winter day, January 15. The percentage of satisfied with internal conditions was calculated with Fanger's Predicted Mean Vote method. A 75 kg male, with a height of 1,70 mts., and a moderate activity of 81 w/m^2 was used as reference. In winter, clothing was 1.2 CLO and air velocity 0.1 m/s. In summer clothing was 0.8 CLO and air velocity 1.5 m/s. ASICLIMA [3] was used to determine solar position during different days of the year, thermal transmitance values of envelopes and heat flows through the different plans of the facades.

During winter days the daytime average temperatures are 21.2 °C in the first floor and 21.6 °C in the ground floor, while the daytime external average is 19.6 °C. The average percentage of satisfied during the winter day are 87% and 86% respectively.

During the winter nights the average temperatures are 21.1 °C in the first floor and 20.7 °C in the ground floor, while the external average is 17.5 °C. The average percentage of satisfied during winter nights is 90% and 87% respectively.

During the summer days, daytime average temperatures are 24.9 °C in the first floor and 24.8°C in the ground floor and external average is 25.1 °C. The average percentage of satisfied during summer days is 91% and 89% respectively.

During the summer nights the daytime average temperatures are 24.1 °C in the first floor and 24.5 °C in the ground floor, while daytime external average is 22.8 °C. The average percentage of satisfied during the summer nights is 94% in either case.

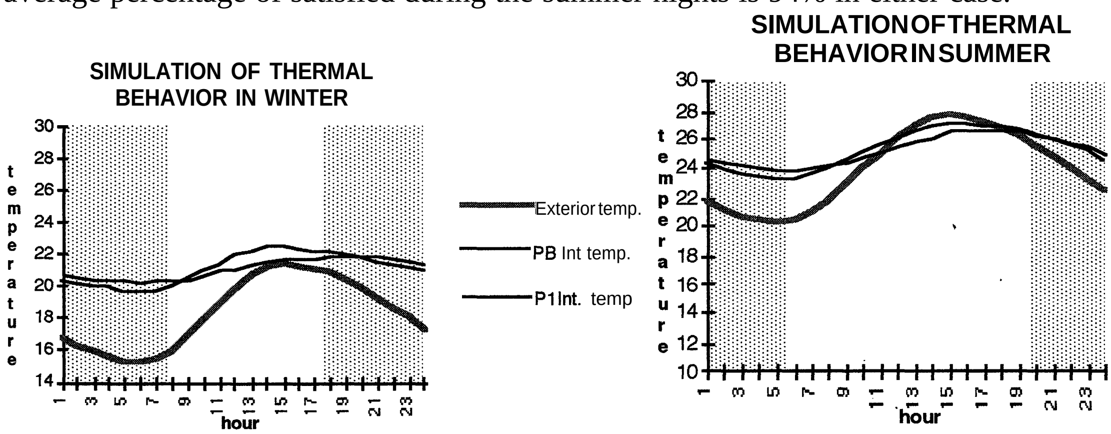

Fig 3 Temperature simulation results in the Tenerife house

3 A bioclimatical house for Tamare, Venezuela: the fourth house

Venezuela is the country with the greatest annual per capita electrical consumption in Latin America. In the Maracaibo lake basin, 40% of electrical consumption is accountable to the commercial and residential sector, and in buildings with air conditioning, about 75% of energy consumption is used to provide mechanical cooling, making this region one of the regions with the greatest per capita energy consumption in America.

The bioclimatic conception, many times perceived as a novelty, is no more than the prolongation of climate adaptive concepts transmitted by individual generations, not architects. Three models of climate sensitive architecture in Maracaibo have existed: the palafitic paraujano building, the colonial-republican building, and the building imported by foreign oil companies. The teachings of these buildings have been forgotten due to the aesthetic popularity of imported styles and cheap energy.

As in the Tenerife building, we propose to integrate architecture with environmental techniques, with improvements on the previous architectural solutions and generating a house which is also adapted to the climatic, social, urban and economic environment of our contemporary cities.

Special importance was given to availability of materials in the eastern coast of the lake of Maracaibo, where Tamare is located, and their environmental characteristics. A steel structure is proposed since steel is used extensively in the oil industry that prevails in this region and much specialized labor is available. Insulating materials are available from the petrochemical industry but do not have a very clean production process.

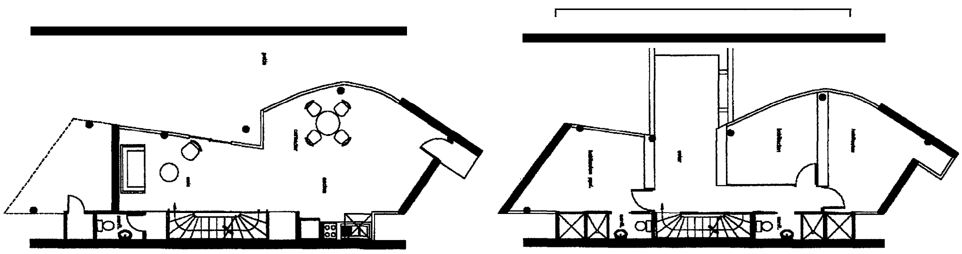

Fig 4 Ground floor and first floor plans of the Tamare House

3.1 Architectural principles

3.1.1 Detached Row Housing

Our proposal for middle income users, in an oil field context near the Lake of Maracaibo, has led us to propose narrow, but rather high, single family units to reduce urban soil consumption and urbanization costs, while at the same time permitting us to perceive the lake horizon. In this situation, where we needed the high density of traditional urban centers in a suburban context, but in an oil culture used to the isolated building, we had to produce a different typology, which could satisfy these apparently contradictory urban and social requirements.

In our proposal, the spaces which characterize an isolated building have been occluded: the backyard and the front garden have been absorbed by the house: the outside has been folded towards the inside. At the same time, the building has been directed upwards and coexists with the exterior, now inside; a channel of light on the side of the property helps to isolate a building that was conceived in a row; thus a typology extracted from the site is born: the detached row house. Thus, the building does not look out onto the street, but rather develops its facade along the band of the patio, contributing, by its curved volumes, to reinforce the feeling of external space.

3.1.2 Horizontal organization of functions in bands

Three bands are organized horizontally: the conditioning band, the conditioned band, and the patio. All the services of the building (kitchen, baths) and the active and passive conditioning systems are located in the conditioning band. The function of this band is to serve the main spaces of the dwelling: bedrooms, family room, dining room, the conditioned band. The patio, is an inner -exterior, lodging vegetation, light and wind. The patio, together with the servant band are responsible for the bioclimatic conditioning of the building. This patio band constitutes another step towards the enrichment of the historical evolution of local patios.

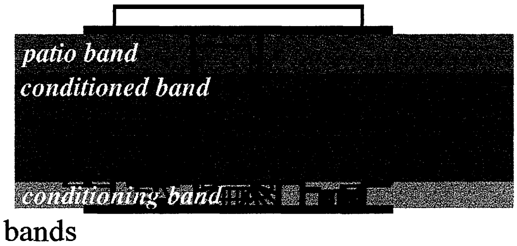

Figure 5 organization in bands

3.2 Bioclimatical techniques and passive systems

Our building increases energy conservation and thermal comfort and uses clean and renewable energy sources to decrease non renewable energy consumption.

In Maracaibo, which has a similar climate data as Tamare, avg. min. Dry Bulb Temperature is 24.7°C, avg. is 27.7°C, avg. max. is 32.9°C, avg. variation is 8°C; avg. Air Velocity is 4.5 m/s, main direction is NE; Avg. max. Relative Humidity is 92%, avg. is 76%, avg. min. is 54%; and avg. yearly precipitation is 490 mm.

Due to extreme climate conditions in the Zulia lake basin, which are even worse in its cities, (thermal islands) our proposal was to design a passive building using natural techniques, mechanical cooling, or both, to reduce energy consumption and approach comfort values. Simulation results show improvements in energy consumption and thermal comfort in all three cases.

3.2.1 Bioclimatical techniques

1. **Shade.** Organization in row houses permits the walls between buildings to be used as shade elements over the facades.
2. **Landscaping** with organic ground cover, and trees, provide lower temperatures around buildings. This cooling effect is not taken into account in thermal simulations, so indoor values could be lower than results indicate.
3. **Precise design of window systems.** Window panes parallel to, the exterior walls are transparent and designed as a window system, which we have called a Matricial Bioclimatic Window, MBW, divided in bands, lines and points, assuming different responsibilities: ventilation, solar protection, natural illumination, visual relations and privacy.
5. **Air movement** is promoted through chimneys, which transfer this air through the living spaces and out to the patio through the MBW. This movement is useful to evacuate hot indoor air, introduce cool air, or achieve comfort by air movement.
6. **Open, shaded, and ventilated indoor floor plans** are proposed, using opaque partitions perpendicular to the servant band and permeable interior partitions perpendicular to these for maximum flow of air.
7. **External finishes in walls and roofs are white.**
8. **Thermal mass** is positioned on the inside of building to reduce thermal oscillations and to work with night cooling. Air cavities for insulation is used in walls, floors and roofs to diminish heat flow by conduction.

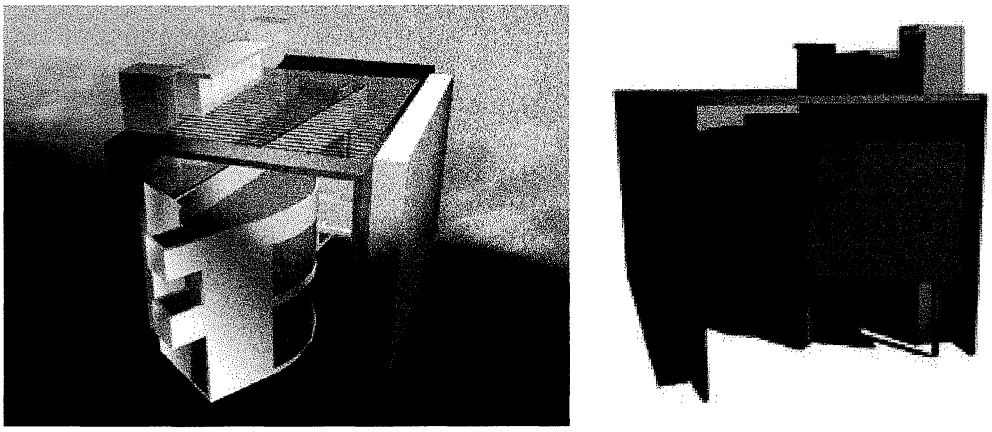

Fig 6 Back and front views of the Tamare House

3.2.2 Passive cooling systems.

1. **Comfort ventilation** by the chimney to the patio, is used to provide direct human comfort by transversal air movement from the chimneys to the patio.
2. **Nocturnal ventilative cooling.** The mass of the building interior is cooled during

the night and then the building is closed during daytime to keep cool air in. When the building is closed electrical fans are used.

3.2.3 Mechanical cooling systems

Air conditioning is proposed as occasionally necessary and useful to cool the building when outdoor conditions are out of the range of passive cooling systems. It can also be used to improve performance of passive bioclimatical systems such as night cooling, which would in this case be mechanical night cooling.

3.2.4 Renewable energy sources

Solar energy is proposed to generate electricity for the electrical fans in the chimney and to heat water for domestic use.

3.3 Thermal simulations

Meteorological data from the urban and airport weather station in Maracaibo was used to analyze thermal performance. Simulations for the worse (May) and best conditions (January) in Maracaibo were carried out. In each case several simulations were done assuming different forms of operating the building which were a combination of opening windows and chimneys to permit flow of air, closing openings to maintain cool air inside combined with fans to achieve comfort and using air conditioning to cool air mechanically.

Two options are shown, the first is opening the building to ventilate from 19:00 to 10:00 hrs and closing it from 10:00 to 16:00 hrs. In this case no mechanical cooling is used, but fans are used to generate air movement for comfort. In January maximum temperatures were generally lower than outdoor values during daytime and significantly lower than the 30 ℃ value recommended by Givoni as the upper limit with which we can achieve comfort with air movement of 2 m/s in developing countries [1]. In May, maximum indoor values reached 33℃ but were still lower than the maximum outdoor.

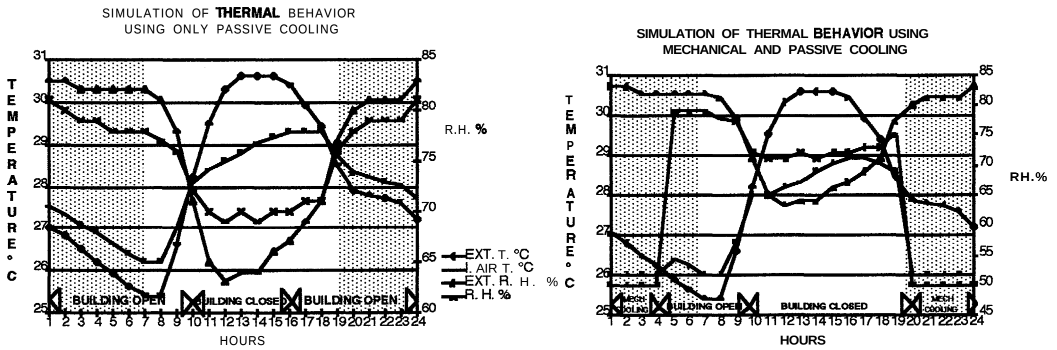

Fig 7 Thermal simulations in the Tamare House

The second option is combining mechanical cooling with passive systems. In this case the building is air conditioned from 20:00 to 4:00 hrs, opened from 4:00 to 10:00 Hrs. and closed from 10:00 to 20:O0. In this simulation indoor temperatures are even lower, never reaching 29 ℃ in January, but reaching 32 ℃ in May. These cases have the disadvantage of high relative humidities (70%) when the building is closed which decreases effectiveness of comfort ventilation.

Other options that have been analyzed are continuos 24 hour cooling, 24 hour natural ventilation and other combinations of closing and air conditioning. All cases provided acceptable results.

Natural illumination values have also been calculated and the averages are between 320 and 210 luxes which are very high compared to necessary standards (100 luxes). There is an adequate distribution of illumination in the spaces, because there isn't a large difference in obtained illumination levels. Uniformity factor is 0.65 which is higher than 0.3 which is the common established limit .

4 House for low income groups in Maracaibo, Venezuela.

This proposal adapts the architectural concepts of the Tamare house, to a proposal for lower income groups. Emphasis is in economy, progressive growth, use of materials found in the site, manufacturing of construction materials by its own dwellers or neighbors, increase of thermal comfort by the use of bioclimatic techniques, and passive cooling systems, and use of materials with low embodied energy. To achieve these objectives manufacturing of soil bricks with a cement content of only 10%, and an artisan elaboration process are proposed. This, together with reduced transportation distances (materials will come from the site) assures an adequate thermal behavior and will reduce environmental pollution. On the other hand, local economy will be improved since brick producers will be members of the community.

5 Conclusion

We think that these two examples demonstrate that it is possible to apply bioclimatical design concepts to an architectural project, avoiding its appearance as an assembly of technological devices. This will increase the possibilities to incorporate bioclimatical devices in new architectural proposals, which will thus have a greater degree of acceptance from its users.

The buildings are expected to be flexible in the management of the sun and the wind, permitting their independent regulation according to comfort requirements and daytime and seasonal variations. The results of simulations demonstrate an adequate application of different bioclimatical techniques and passive cooling systems, for two different climates. However the monitoring of the thermal conditions within the houses, will permit to evaluate with greater precision the behavior of the proposals and the degree of satisfaction of the users with the proposal will be the definitive evaluation of the effectiveness of our proposals.

6 Acknowledgments

We are grateful to Consejo de Desarrollo Cientifico y Humanistico CONDES of the University of Zulia and PDV, the National Oil Company for their grants that have permitted us to develop these research projects. Also to our research assistants L. Rodriguez, M. Moran, N. Soles, R. Fernández, E. Sáez.

Projecting Energy Savings from Daylighting in Partitioned Open Plan Spaces

Gon Kim
Department of Architectural Engineering
Andong National University, Andong, KOREA 760-749

Abstract

Daylighting has proven to be an important opportunity area for energy savings in buildings in hot and humid climates. Modern office buildings are making increased use of natural light to improve lighting quality while reducing energy costs. A prevalent configuration in office interior spaces is the open plan, which is a configuration of varying-height partitions or panels which are free-standing or integrated into furniture systems. From the viewpoint of lighting, this environment presents a unique opportunity for use of natural light -- mainly because there are no floor to ceiling partitions. In a space with partitions and furniture, illuminance distribution on the work plane is influenced by the inter-reflection and obstructions to which light emitting sources are subjected, creating light attenuation and shadows. Consequently, more accurate daylighting and electric lighting performance data are needed not only for compensating likely light loss but for maximizing energy savings.

This paper presents results of a recent research project that uses scale and computer model measurements to determine lighting performance in partitioned open-plan spaces. Twelve prototypes of interior layout modules in common office buildings were selected for this study. A latitude of 30°N. was selected, typical of the hot and humid areas of the U.S. Results from the evaluation of electric lighting performance show that, on the average, a reduction of 20% was experienced in the partitioned area, compared to the nonpartitioned area. In daytime, the carefully designed features of a multistory office building can successfully permit most of the space to be daylighted and electric lights to be dimmed by a cost effective operated system so that the attenuation can be easily compensated by introduction of daylight. Building energy simulation with measured daylight illumination levels and the performance of lighting control system indicates that daylighting can save over 70 percent of the required energy for general illumination in the perimeter zones through the year. A 25 % of electric energy for cooling may be saved by dimming and turning off the luminaires in the perimeter, zones.

Keywords : Daylighting, Electric Lighting, Energy, Layout, Partition

1. Introduction

A dramatic increase in the design of commercial buildings with daylighting manifests a renewed discovery of the architectural art of glazing as well as an energy-saving feature. Use of daylighting has a strong emotional appeal and numerous studies have' conclusively demonstrated a marked preference for daylight over any other form of lighting. Also, reducing the artificial lighting when natural daylighting is available has economic benefit because lighting accounts for 30-40 percent of the electrical operating costs in commercial buildings or approximately $0. 80/ft^2/year and yet the average commercial building is unoccupied approximately 75 percent of the time. Most lighting professionals, however, have enjoyed the convenience of non-daylit building design, with a constant electric lighting level regardless the. consideration for level of daylight in the space. The practical usefulness of optimal reintroduction of natural light into office perimeter spaces is fulfilled by integration of .the electric lighting with proper luminaire control in a view toward building energy savings. In view of this situation, obviously, what is needed here is the basic daylighting illuminance data and design guidance to utilize both electric illuminance characteristics and daylighting availability of the perimeter layouts with generalized -interior configuration.

The particular emphasis of the study is placed on parametric evaluation of the effects of the representative configuration of partitioned open space on daylight levels, electric lighting design and energy saving in the office building. For this purpose, this study aims to determine the impact of partitioned interior types on the performance of a conventional electric lighting design and to explore the integration method between daylighting, electric lighting, controls and the configuration of partitioned interior on the basis of measured daylighting performance data.

2. Interior layout in modern offices

2.1 Layout options

Most new building designs produce a block-type structure which is well lighted and air conditioned, and which is divided by a few access corridors radiating from the central service core. This type of construction places all or majority of the private offices in the core area and allocates space along the building perimeter for others. This concept arises from the premise that employees performing- routine tasks which keep them at their desks almost entire work day require both the psychological advantages and daylighting benefits of window space. In brief, an office perimeter is typically designed according to three planning options; closed, open, and combination. Each option is distinguished by the proportion of partitioned or enclosed-to-open space that exists in the layout. The open plan is a configuration of varying-height partitions or panels that are free-standing or integrated into furniture systems. This is, perhaps, the most typical planning option in the perimeter spaces of an office building.

2.2 Configuration of partitioned interior space

Working within the open office environment, there are certain basic forms and shapes that the, designer uses to organize and manipulate the interior space. Office layout is often structured by the independent workstations or clustered groupings organized in a variety of unit module of workstations. In the initial investigative stage in this study, accordingly, a procedure to generalize the configurations of typical partitioned space modules have been involved. In modern office, space standards establish geometry and square footage criteria for an individual,' group, organizational function. The inevitable approach probably is to investigate typical configurations of furniture and functions for the interior space. In the layout of partitioned open space, a common design is to place the unit workstation modules in rows. This method will permit the use of bank-type partitions as a divider for those activities which require visual privacy while still obtaining maximum utilization. The unit workstation should face the same direction unless there is a compelling functional reason to do otherwise. Figure 1 illustrates a set of partitioned configuration which can commonly be found in common office buildings.

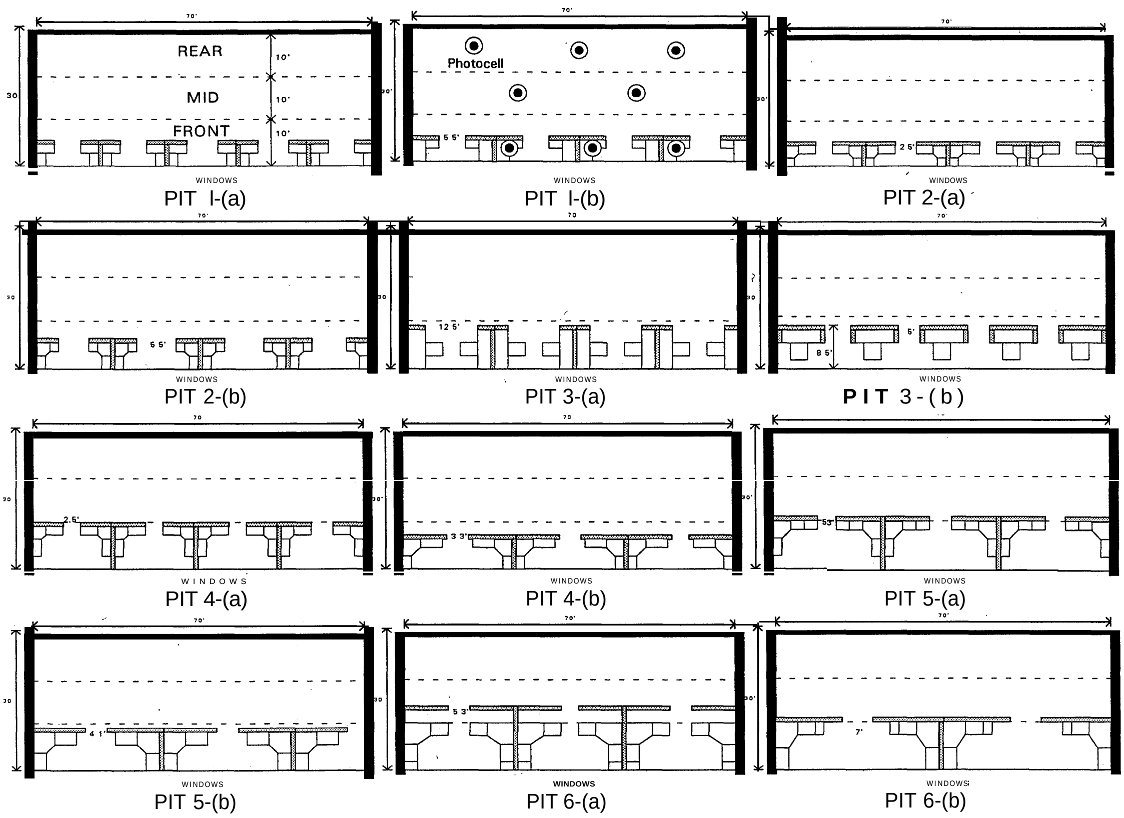

Figure 1. Configurations of partitioned interior type (PIT)

3. Daylighting measurement

3.1 Scale model and data acquisition

With reference to the units partitioned 'space selected previously, a total of 12 partitioned interiors has been established within a perimeter of an office interior measuring 70' (W)x 30' (D) as shown Figure 1. Two ceiling heights, that is, 10' and 12', were considered and a rectangular-shaped window on one wall measuring 68'(W) x 6.5'(H) with 10' high ceiling and 68'(W) x 8.5'(H) with 12' high ceiling were used as the sole sources of daylighting. Also, to 'improve the practical usefulness of the data, two types of shading devices for full and partial shading were applied.

This study is based upon a systematic series of measurements within the sky simulator at Texas A&M University by using an indoor sun simulator and utilizing photometric sensors to read illumination levels. As shown in Figure 1, three different locations - the front, mid, and the rear spaces - were separately considered because each depth of space from the window wall has different reflected sunlighting potentials. The characteristics of each partitioned space type in terms of daylighting performance were determined from the measurements under diffuse sky conditions without sun. This measurement represented the performance results in terms of *Daylight Factor* (DF), a ratio between indoor horizontal illuminance from daylight between exterior horizontal illuminance.

3.2 Daylighting strategies

The evaluation of partition system must be in integration with building envelope system as both daylight admitting system and thermal barrier between interior and outdoor so that the daylighting measurement data can be used in building energy simulation. In this process, optimal building envelope can be inferred for maximized energy saving due to its thermal and lighting properties. A total of 10 different building envelope system types which consist of ceiling height, window size, shading, and ground reflectance are defined as shown in Table 1.

Table 1 Building envelope system types

Type	Ceiling height	Window size	Shading	Ground Ref.
BLDG 1	10'	68' x 6.5'	No	20 %
BLDG 2	10'	68' x 6.5'	No	40 %
BLDG 3	10'	68' x 6.5'	Full	20 %
BLDG 4	10'	68' x 6.5'	Full	40 %
BLDG 5	12'	68' x 8.5'	No	20 %
BLDG 6	12'	68' x 8.5'	No	40 %
BLDG 7	12'	68' x 8.5'	Partial	20 %
BLDG 8	12'	68' x 8.5'	Partial	40 %
BLDG 9	12'	68' x 8.5'	Full	20 %
BLDG 10	12'	68' x 8.5'	Full	40 %

4. Artificial lighting design for partitioned interiors

4.1 Selection of lighting fixture

The most important factor in designing of an electric lighting system is the selection of the light source and its layout. Presently, a high percentage of office lighting utilizes fluorescent rapid-start lamps and low efficacy magnetic ballasts. A typical fluorescent lighting system consists of a three-tube fixture with cool white 40W bulbs (F40cw). Parabolic fixtures, which is the selected light source for general illuminance in this study, are linear parabolic troughs with lamps positioned at the focus. These fixtures came into widespread use during the 1970s in offices. Most parabolic fixtures are louvered luminaries with parabolically shaped white or metallic troffers. The louvers are open grids of opaque, semi-translucent, or reflective shielding and diffusing media that collimate down-coming light rays. The specification of the luminaire is described in Table 2.

Table 2. Luminaire Description

Description	2’x4’ 3 Lamp Parabolic Troffer
Configuration	Lamp	Fluorescent (F40cw)
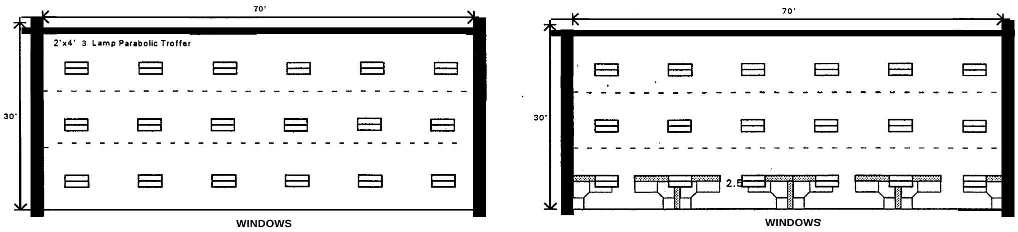
Lamp Watts	40 W
Total Watts	120.0 w

4.2 Electric lighting system design in totally-open interiors

The design of electric lighting system for partitioned open-plan requires additional consideration to compensate for the likely loss of illuminance caused by the vertical obstruction. To estimate the impact of the partition system on general illumination environment, representative partitioned interior types which have been used are selected, and then a conventional approach to design an electric lighting layout is applied for the partitioned space. The impact of the presence of the partition systems is expressed in terms of light reduction by comparing to a totally open plan.

To get an average 50 fc of ambient illumination in a totally open plan, a luminaire layout is proposed on the basis of conventional design method of electric lighting and is illustrated in Figure 2. Eighteen lighting fixtures are asymmetrically arranged forming a 3 by 6 rectangular matrix on the 12-foot high ceiling without suspension. In this 3x6 layout of the luminaries, on the average, a total of 2,196W is required to get an average illuminance of 50 fc and generate a power density of 1.05W/ft^2 for electric lighting only. The layout of the luminaries is also applied to the selected partitioned open-plans so that the impact of the presence of partitions on the electric lighting performance can be estimated in term of light reduction.



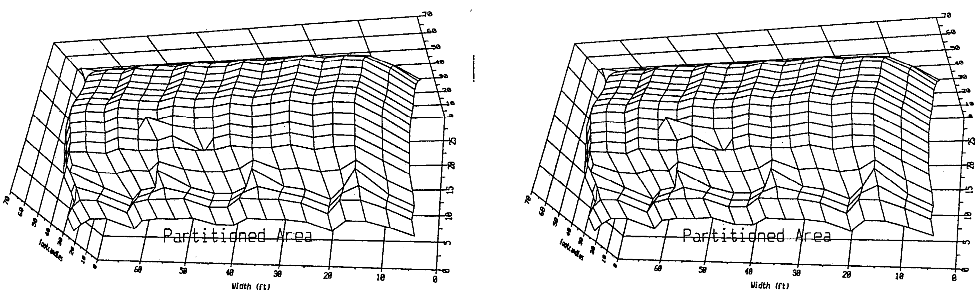
(a) the open-plan (b) a partitioned open-plan (PIT2)

Figure 2. Luminaire Layouts

The performance of the electric system design in totally open interior is calculated by Lumen-Micro 6.03 and the results show that the average, maximum, and minimum level are 54.5, 67.1, and 3 1.5 fc, respectively. In spite of even distribution of the luminaries, some degree of fluctuation with a standard deviation of 6.67 in illuminance level is unavoidable. On the average, in the partitioned interior, a reduction of 4 fc occurred through the whole space but more attenuation is detected around the partition, showing about 15 percent drop, compared to the basecase open plan. Various approaches can be proposed to compensate for the light attenuation.

4.3 Artificial lighting layout for partitioned interiors

It is suggested that the attenuation in light level and the deterioration in qualitative lighting by shadow effect may be mediated by both increasing the number of luminaire , and more dense arrangement of the luminaries on the ceiling in the partitioned open-plan interior. The feasibility test for the implementation is performed by the Lumen-Micro.



(a) PIT 2 (b) PIT 4

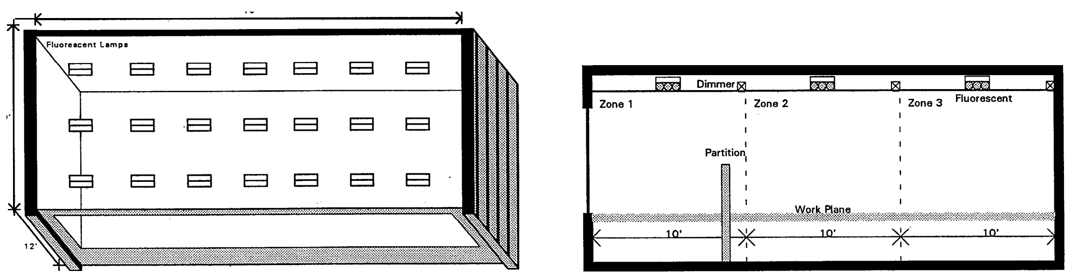
Figure 3. Electric light distribution in partitioned open spaces

As shown on Figure 3, results from the evaluation of electric lighting performance show that, on the average, a reduction of 20% was experienced in the partitioned area, compared to the nonpartitioned area. In order to compensate the attenuation, the electric power density should be increased by 20% to provide more light, resulting in increased number of luminaires. In the building interior model for the study, an extra power density of about $0.25W/ft^2$ is demanded for the partitioned area.

5. Building energy simulation

5.1 Target building plan and lighting layout

Perimeter spaces of an office building typically benefit from daylight. It is assumed that this is a one-story building without an outdoor obstruction. Figure 4 shows the geometry of the one story office space with dimensions of 70'x30'x12'. The luminaire layout provides an average illumination of 60 fc in case of the presence of the partitions as examined before. On the process of energy simulation by the ENERCALC developed in Texas A&M University, a continuous dimming system located at the back of each daylit zone reflects the variation of daylight level in the partitioned spaces.



(a) Building Geometry

(b) Building Section and Controls

Figure 4 Model building and layout of luminaries for energy simulation

5.2 Energy savings due to daylighting

Comparing with the extreme case which has no daylight, on the average, daylight plays a big role in reducing a 25 % of the, annual cooling load and a 70 % of lighting load for general illumination. Figure 5 illustrates the amount of required energy for general illumination in each partitioned space type. In spite of the presence of the various types of partitions, the partitioned open plan has almost same potential to utilize daylight for not only general illumination and but building energy savings. Unless daylight availability of a building is extremely higher than usual, however, other design factors, such as window or outdoor environment must be well incorporated with the interior condition in order to compensate for the blocking effect of the vertical partitions.

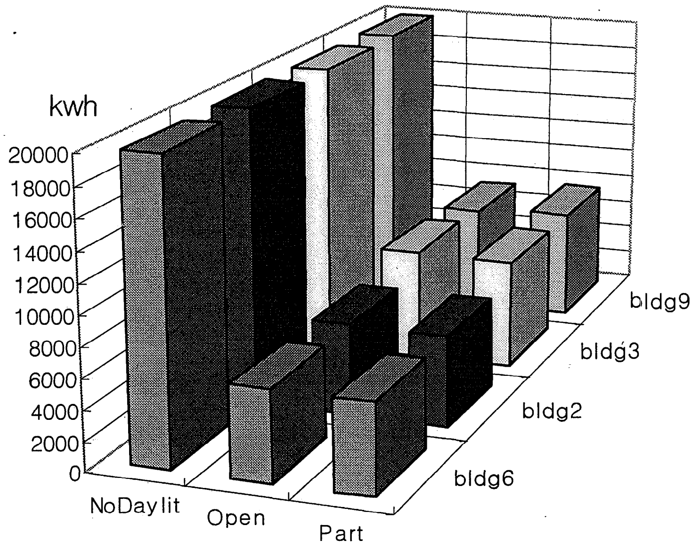


Figure 5 Annual energy consumption for lighting

6. Conclusion

Results from the evaluation of electric lighting performance show that, on the average, a reduction of 20% was experienced in the partitioned area, compared to the nonpartitioned area. In daytime,, the carefully designed features of a multistory office building can successfully permit most of the space to be daylighted and electric lights to be dimmed by a cost effective- operated system so that the attenuation can be easily compensated by introduction of daylight. For the period when daylight is not available, however, the electric power density should be increased by 20% to provide more light, resulting in increased number of luminaires. In the building interior models for the study, an extra power density of about 0.25W/ft^2 is demanded for the partitioned area. The results from building energy simulation with measured daylight illumination levels and the performance of lighting control system indicate that daylighting can save over 70 percent of the required energy for general illumination in the perimeter zones through the year. A 25 % of electric energy for cooling may be saved by dimming and turning off the luminaires in the perimeter zones.

Moisture control in buildings - How can varying outdoor climate be allowed for when designing the structure?

E Harderup
Lund Institute of Technology, Lund, Sweden
P I Sandberg
Swedish National Testing and Research Institute, Borås, Sweden and Lund Institute of Technology, Lund, Sweden

Abstract
This paper describes the general need for secure protection against moisture, and methods for designing the structure in this respect. Ensuring that all the possible moisture loads on different parts of the building have been systematically considered creates the right conditions for designing structures without moisture problems.

An important part of the work of designing structures to deal with moisture loads is to estimate the risk of damage and problems resulting from random variations in the properties of materials, indoor and outdoor climate and user/occupant habits. This paper describes, in particular, the effect of a varying outdoor climate and methods for allowing for it when calculating the moisture conditions of various parts of a building.

By performing calculations for a number of cases over many years (196 14990) and by studying the spread of the results from one year to another, it is possible to identify the reference (average) year and the most severe (extreme) year. With this information, appropriate safety factors for design calculations can be determined. The paper describes calculated moisture conditions and presents examples of design safety factors for different moisture problems encountered in different types of designs.
Keywords: calculation, climate, design, moisture, random, safety

1 The need for improved moisture protection

There is general agreement today that a dry building process and dry structures are important factors in producing healthy buildings. In addition, we know that, in many cases, moisture is the cause of poor durability and limited life of materials and structures. **This** means that controlling and restricting moisture content, and providing means of guarding against the inconveniences and damage caused by moisture (moisture control), are important. Good moisture control can be achieved only through good design.

Moisture control through appropriate design is needed both for new buildings and for repair/maintenance. Such work will predominate in Sweden for some years into the future, and particular attention must be paid to determining the methodology so that it becomes a useful aid for the work.

Moisture control through design applies not only to the actual design work and how the structure is to be arranged: it must also consider conditions during the construction and use stage. The designer (or someone else having the appropriate authority and overview of the whole) must be able to specify constructional details and methods and limitations to be observed during use.

2 Designing for moisture resistance

Moisture control through appropriate design relates to the elements of the building process intended to ensure that the building is not damaged, or its users inconvenienced, whether directly or indirectly, by moisture. Figure 1 is a schematic illustration of the components of such moisture control through design.

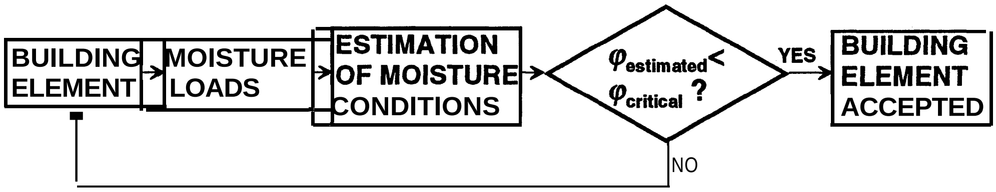

Figure 1. Simplified diagram of the various components of moisture control through design.

Moisture control through appropriate design considers each part of the building and its associated details separately. All the necessary input information on the characteristics and dimensions of the materials for each part of the building is collected. We also need to assess the types of damage that could occur and decide on acceptable levels of risk of damage and inconvenience.

Internal and external moisture loads for the particular part of the building need to be carefully determined. External climate loads can be determined from meteorological data.

Calculations, experience or other aids can then be employed to calculate or assess the expected moisture loads, which can then be compared with critical values. This part of the work can vary widely, ranging from meticulous computer calculation of expected spatial and temporal moisture loads to a brief observation that some particular material is insensitive to moisture, with the result that the expected moisture load is therefore uninteresting.

If this systematic consideration of the moisture load on the various parts of the building shows that the expected risks of moisture damage or inconvenience are acceptable, then moisture control through design can be regarded as completed. However, if unacceptable risks are identified, the design details need to be changed, or it may be necessary to specify special building conditions or impose restrictions on use.

3 Risk and safety philosophy

An important aspect of moisture control through design is the matter of safety factors and the safety philosophy. Material properties, climate and user habits all vary randomly, and forecast moisture conditions or loads cannot be expressed as hard and fast values but as probabilities of their occurrence. This probability can then be set against the risk of certain damage or inconvenience occurring.

This paper discusses methods of allowing for the stochastic variations in outdoor climate in the process of moisture control through design. For this purpose, material properties, user habits and other factors that can vary are assumed to be known and constant, although in a complete moisture design process they would have to be considered in the same way as variations in the outdoor climate.

There are a number of different ways in which allowance for these variations can be made:

- ***Determination of the frequency function*** of the particular moisture condition. This requires the moisture conditions to be worked out on an hour-by-hour (or day-by-day or month-by-month) basis over a very long period of years of natural climate variations - in principle, for as long a period as the life of the building. The risk of a particular moisture condition arising can then easily be read off. This method requires an excessive work input. In addition, it requires climate data for past years to be used as a forecast for future years, which means that it cannot consider long-term climate variations.
- ***The extreme value method.*** See figure 2A. This involves calculating moisture conditions resulting from an extreme outdoor climate, e.g. the worst that has occurred in a 50-year period. This value (which in this example can be assumed simplified to carry a 2 % risk) is then used to compare with the critical values. In addition to the availability of a large quantity of climatic data, the method also requires an understanding of which climate conditions are most unfavourable for various types of moisture damage. However, there is no need for an additional safety factor, as this is already incorporated through selection of the extreme climatic condition..
- ***The normal value method.*** See figure 2B. This involves calculation of the moisture conditions on the basis of normal (reference) outdoor climate values. This data can be taken from that for a single real year, regarded as typical of several years, or can be a postulated year, known as a Test Reference Year (TRY). The values of moisture conditions calculated in this way must be corrected in some way, $\Delta\varphi$, *in* order to

represent an extreme year. The advantage of this method is that it is quite easy to obtain data for a normal year, although a drawback is that the necessary corrections for moisture conditions depend on the type of moisture damage and on the type of climate.

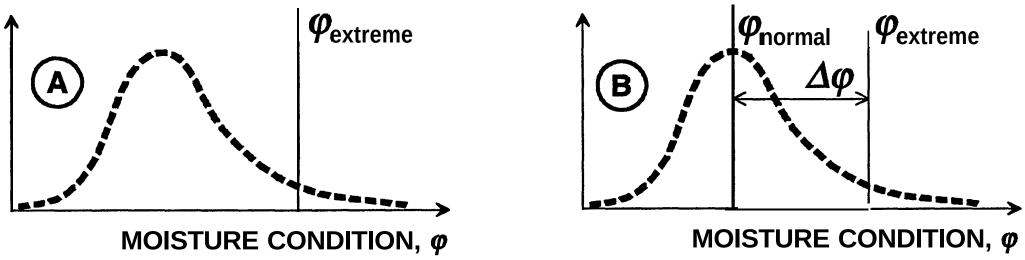

Figure 2. Frequency curves for moisture conditions. φ is used here as a general designator of a moisture condition that can be relative humidity, moisture content, moisture ratio, capillary saturation etc. A illustrates the extreme value method, by which an extreme moisture condition is calculated from data for extreme climatic conditions. B illustrates the normal value method, by which the extreme moisture condition is obtained by applying a correction ($\Delta\varphi$) to the normal (reference) value of moisture condition.

A research project being carried out at the Lund Institute of Technology [1] is intended to describe methods of determining the most unfavourable moisture condition that will occur during the lifetime of a building. Suitable corrections for converting the reference year conditions to those of an extreme year are being developed by investigating how moisture conditions vary from one year to another. By comparing calculated results for many years (30 years), it is possible to identify the most unfavourable year. A correction for the variations in climatic data is then determined as the difference between the moisture conditions for the most unfavourable year and those for the reference year. This correction can be applied either in the form of a multiplying factor or as an absolute addition. The method is illustrated by examples in Sections 4 and 5.

4 The drying-out potential

In certain cases, the maximum permissible moisture input to indoor air (v_{FT} in kg/m^3) can be described using the drying-out potential, known as the II-factor [2]. This factor describes the mean value of the difference between the saturated vapour concentration of the external surface, v,(T) and the vapour concentration in the outdoor air, v_e. A condition for drying out is that $v,(T) > v_i$ i.e. that $v,(T) > v_e + v_{FT}$, from which we obtain the condition $v_{FT} <$ II.

The mean value of the Π factor between times t_a and t_b is

$$\Pi = \frac{1}{t_b - t_a} \cdot \int_{t_a}^{t_b} \left(v_s(T) - v_e \right) dt \qquad (1)$$

The temperature, ***T*, is** an equivalent temperature which allows not only for the air temperature but also for solar radiation or for both solar and long-wave radiation. This example is for a horizontal roof and the effect of snow on the roof has been ignored.

Taking the climatic data for Bromma, near Stockholm, and calculating a **Π** factor for each year, we obtain the result shown in Figure 3. The mean values of **4,5** and **2,7 g/m³** respectively are shown by the solid lines in the diagram.

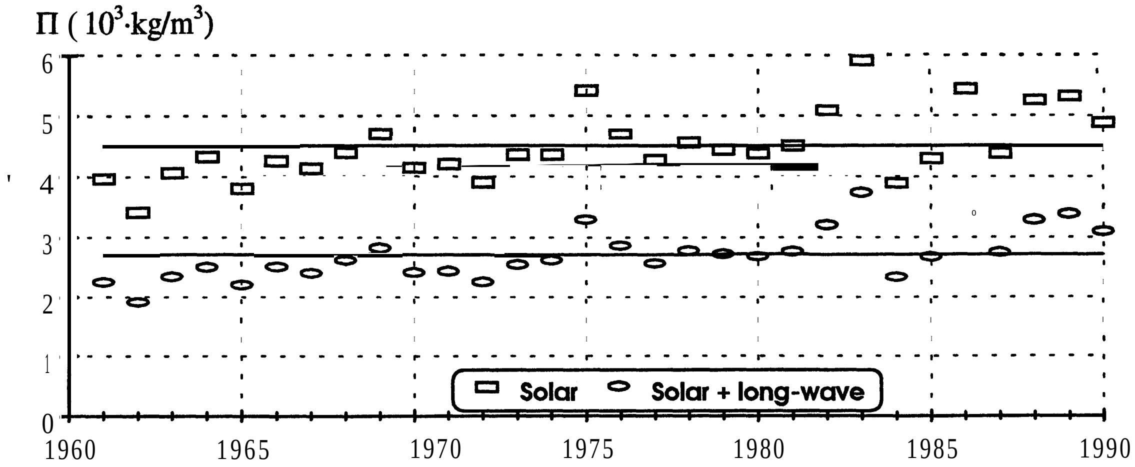

Figure 3. Variation in drying-out potential for a horizontal roof in Bromma with allowance for solar radiation and for solar radiation plus long-wave radiation.

The year that most closely agrees with the mean value is referred to as the Mean Deviation Year (MDY) and used as the reference year. The concept of MDY presupposes that the moisture conditions can be characterised by a value for each specific year. The MDY and the extreme year are normally different for different types of moisture conditions and structures. In Figure 3, the **MDYs** are 1981 and 1979 respectively. The difference in the **Π** factor (**ΔΠ**) between the most unfavourable year (the extreme year) and MDY is the correction needed for conversion of a result for a reference year to that for an extreme year.

ΔΠ can be expressed either by a term or by a factor:

$$\text{AI-I} = \Pi_{ext} - \Pi_{ref} \tag{2}$$

or

$$k_\Pi = \frac{\Pi_{ext}}{\Pi_{ref}};\ \Delta\Pi = k_\Pi \cdot \Pi_{ref} - \Pi_{ref} = \Pi_{ref} \cdot (k_\Pi - 1) \tag{3}$$

As the most unfavourable year in this example is that with the lowest **Π** factor, **ΔΠ** is negative and $k_\Pi < 1$. In the example shown in Figure 3, with solar plus long-wave radiation, the most unfavourable year is 1962 and we obtain: $\Delta\Pi = -0{,}8$ and $k_\Pi = 0{,}7$.

The postulated path in a moisture design is that the designer starts by calculating the moisture conditions for the reference year and then applies an absolute correction or multiplies by a correction factor to obtain values for the extreme year:

$$\Pi_{ext} = \Pi_{ref} + \Delta\Pi \quad \text{or} \quad \Pi_{ext} = k_{\Pi} \cdot \Pi_{ref} \tag{4}$$

In order to be able to do this, the designer needs to know the reference year and suitable values of absolute correction or correction factor. The research project mentioned above is developing methods of determining suitable reference years, absolute corrections and correction factors. As, in principle, each type of moisture condition, structural design and geographical region has its own reference year, absolute corrections and correction terms, it will be a long time before we have all the necessary information. However, the work has revealed certain patterns, which can lead to some general recommendations: see [1] for more details.

5 Summer condensation

The calculations use a computer model for transient calculations of the combined air, moisture and heat transport in one dimension **[3].** The model is based on the method of finite differences, with explicit forward difference in time. Compared with the original version, a number of modifications have been made:

- Several years of real climate data are used in the modified version, instead of data for a single year as used by the original version. This means that moisture and temperature conditions can be calculated for a range of years, e.g. from 1961 to 1990.
- Moisture transport has been complemented by simple equations for the effect of driving rain.
- The vapour permeability has been changed from a constant value to a function of the relative humidity.

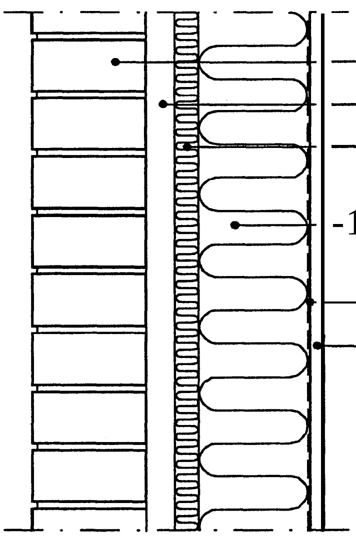

Figure 4. A section through the cavity wall.

The design selected is a cavity wall, and is shown in Figure 4. The effect of the cavity has been neglected. The wall has also been assumed to be completely airtight, and the effect of moisture convection has been ignored. Details of the material properties and calculations can be found in [l].

The meteorological data is that for 1961 to 1990 for Ronneby, in south-east Sweden. Moisture conditions for the reference year (MDY) and for the extreme year, together with the corrections for variation in climate data, are described.

The example calculates the percentage number of cases having relative humidities of 100 %, $f^{\varphi=100}$, in the thermal insulation immediately outside the vapour barrier. This phenomenon of condensation on the outside of the vapour barrier is usually referred to as summer condensation. It occurs when the sun warms up damp brickwork and vapour transport occurs from the outside inwards, rather than the normal transport from the inside outwards. Figure *5* shows the theoretical results for different directions of the wall for MDY and for the extreme year.

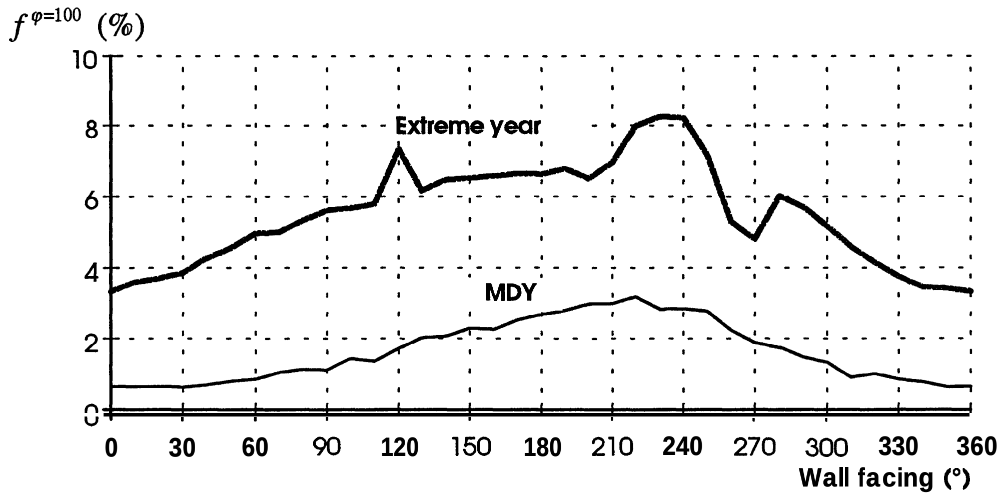

Figure 5. Calculated values of $f^{\varphi=100}$ in the thermal insulation on the outside of the vapour barrier for all directions of the wall in Ronneby, for MDY and the extreme year. North is represented by 0°.

The difference in $f^{\varphi=100}$ can be expressed either by a term:

$$\Delta f^{\varphi=100} = f_{ext}^{\varphi=100} - f_{\mathrm{MDY}}^{\varphi=100} \quad (5)$$

or by a factor:

$$k_{f(\varphi=100)} = \frac{f_{ext}^{\varphi=100}}{f_{MDY}^{\varphi=100}} \quad (6)$$

The value of the correction term or factor varies for the different external directions. If we calculate the corrections as a mean value for all directions, we obtain 3,9 % and 4,1 respectively. If we use the calculated values of $f^{\varphi=100}$ for MDY and apply the above values for correction term and correction factor to calculate $f^{\varphi=100}$, we obtain the results as shown in Figure 6, from which it can be seen that the best agreement is obtained when using a correction term. In addition, this gives the best estimate of the extreme year for those external directions with the highest loadings. In southern Sweden, driving rain comes mainly from the south-west, with the effects of sunshine also being the greatest in this direction, which explains the differences between the different directions as shown in Figure 6.

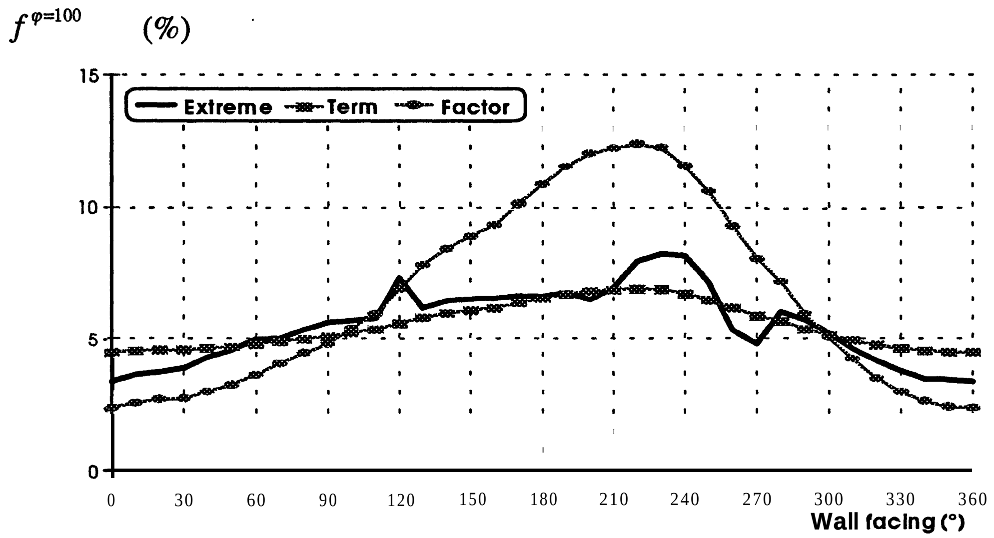

Figure 6. Calculated values of $f_{ext}^{\varphi=100}$, using real weather data, reference years and constant correction term or correction factor respectively.

6 Conclusions

The examples show that the variation in climate from one year to another can give considerable differences in calculated results. Design can allow for the effects of extreme years by using a reference year and then correcting the result. Each type of moisture condition and structure requires knowledge of the reference year and the correction. An absolute (incremental) correction term is more suitable in some cases, and a (multiplying) correction factor is more suitable in others. This paper has described various ways of arriving at this knowledge.

The self-contained dwelling

M. Machado, F. Mustieles, P. La Roche, I. de Oteiza

Instituto de Investigaciones de la Facultad de Arquitectura, IFA, Universidad del Zulia. Maracaibo, Venezuela.

Abstract

The Fourth House is a bioclimatic proposal that improves the three bioclimatic and historic models existing in the region The Maracaibo Lake: the indigenous model or *palafito* (the first model), the colonial-republican house (the second model) and the "oil company" dwellings (the third model). The Fourth House is a contained dwelling composed of inhabited objects and a vertical patio, wrapped by a bioclimatic and secure container. The container and the patio work together to create habitable objects. The envelope is the most important element to consider in the design process of bioclimatic sensible bulidings, because of the heat losses and gains throught it. In intertropical latitudes and extremely hot and humid climates, like the Maracaibo lake basin. The elements of the envelope may protect and isolate the interior space from the sun, without cutting the breeze: this is the container's role.

The container is the result of a "two folded" process, both material and inmaterial.

The material fold is opaque and heavy; its climatic responsabilities concern the protection from solar radiation; it also works as a partition wall, as structural support and as a space of services. It's composed of three main bioclimatics elements:

- the *Rampart* -a thick services wall-, responsible for the protection of horizontal plans in the inhabited objects, conducting the breeze, previously cooled by evaporative cooling inside the objects;
- the *Ying-Yang ground-floor* composed by an inorganic ribbon to keep interior temperatures at low value, and an organic ribbon to minimize the reflection of solar radiation and cool outdoor air;
- the Green *Wall* responsible for protection of vertical plans in the inhabited objects, ınd of conducting and cooling the breeze lengthwise, which has both a physical and sychological effect.

The inmaterial fold is permeable and light; its climatic responsabilities concern the otection from solar radiation, regulating ligthing and ventilation. It's composed of o main bioclimatics elements:

- the *Bioclimatic Geometrical* Roof defined by heliosurfaces, protecting from solar iation, and generating electricity and hot water, wind points, collecting the breeze natural ventilation of the inhabited objects, and green lines, protecting from solar ation by an evaporative-transpiration process, and regulating light by filtering, and ilation;
- the *Threshold* responsible for regulating light and ventilation; it defines the entries contained dwelling; a vertical frame works for security purposes.

ywords: Bioclimatic container design, natural ventilation, solar radiation.

1 Introduction

In intertropical latitudes with hot humid climate, such as Venezuela,. building envelopes must reduce influence of solar radiation, and in these, roofs and windows must receive special attention. A bioclimatical house for Tamare, Venezuela, is proposed. This building incorporates design principles from traditional indigenous, colonial-republican and oil company houses in the Maracaibo lake basin to generate a new prototype adapted to contemporary urban third world problems.

In this paper we will discuss our proposal for the container system, which we have called *BC,* a *Bioclimatic Container.* BC has been designed as a system of elements with specialized functions, assuming different bioclimatic responsibilities. In the first part we will review the evolution of the envelopes in the three previous bioclimatic models; in the second part we will explain the bioclimatic techniques incorporated to the BC in the context of a bioclimatic dwelling, called the Fourth House. Simulations of the bioclimatic behaviour of the Fourth House and preliminary evaluations of BC have been carried out and the results are shown in this paper.

2 From a bioclimatic envelope to a bioclimatic container

Three previous bioclimatic models have been developed in Zulia, the most important oil producing state in Venezuela: the traditional indigenous house or *palafito* (the first model), the colonial-republican house (the second model) and the oil company house (the third model). These models proposed three different bioclimatic envelopes (figure 1).

2.1 The envelope in the traditional indigenous house

The zulian traditional indigenous house or *palafito* is really an inhabited filter; the different components of the envelope -floors, walls and ceilings- are permeable; sunlight, wind, dust and water are regulated by these three components. The floor, built with cane poles, permits the presence of the lake inside of the house; the floor becomes thick. The walls are a big flat filter regulating illumination, radiation and wind; they are walls-celosias in wich other windows are included but with different responsibilities. The ceiling, thick and built in rush -enea thatch-, permits the house to breathe, evacuating the heat, but impeding the rain to penetrate. The rush -palm leaves- is a light and insulating material that doesn’t store heat nor transmits it to the inside.

Figure 1: The three previous bioclimatic models existing in the region of the Maracaibo lake.

2.2 The envelope in the colonial-republican house

The Maracaibo colonial-republican houses were built between the second half of the XIXth century and the first decades of the XXth century, and is the legitimate heiress of the main architectural and bioclimatic principles of the Spanish colonial house. It's a rectangular house in a row house arrangement, with a lateral courtyard; it has only one colored facade, with a high door accompanied with one, two or three high and thick windows.The roof has a double inclination towards the street and the patio; it's covered with clay tiles supported by a wooden structure resting on relatively thick walls, built with a mortar of clay and soil contained by cane poles, generally called *bahareque.*

2.3 The envelope in the oil company house

The architecture of the oil company house has inhereted large roofs and eaves. Its development lasted more or less four decades (1920-1960), and is the result of the experience of dutch, british and american transnational corporations experience in the housing sector for tropical areas. Each house is an isolated rectangle, completely surrounded by gardens, most often with four white façades, with its windows and doors protected by a large eave. The roof has a slope in four directions, covered with thin zinc sheets and a suporting wooden or metal structure; the outside enclosures are wooden with an air chamber. The floors are also wooden, that resemble a movable platform.

3 The Fourth House: a bioclimatic container

3.1 The Fourth House

The <u>Fourth House</u> has been conceived as an isolated house but inside a system of row houses in an effort to reduce the cost of urbanisation and the consumption of urban land. The <u>Fourth House</u> deals with the apparent contradiction existing between rationalising urbanisation costs and considering the specific urbanisation way of life. The spaces of the isolated house have been occluded: the backyard and the front porch have been absorbed by the house like the removable little tables in an airplane: the outside has been folded towards the inside. The house becomes vertical and lives in parallel with the occluded exterior; wrapped by a bioclimatic container; the container and the patio work together to create habitable objects (figure 2).

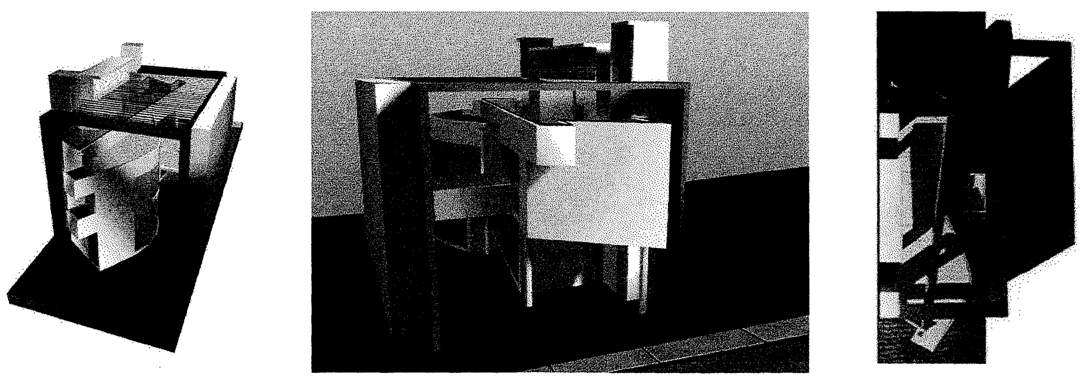

Figure 2: The Fourth House: a new bioclimatic model.

The Fourth House is organized in three bands: the *conditioning*, the *conditioned* and the *patio*.

In the *conditioning band* the passive conditioning systems are installed (eolic chimney) as well as the active systems and the service area (kitchen and bathrooms).The function of this band is to serve, conditioning, the main spaces of the dwelling: dormitories, living, dining, the *conditioned band*.

The *patio band* is an inner exterior, lodging the vegetation, the light and the wind. The *patio* and the *conditioning bands* are responsible for the bioclimatic conditioning of the house. Additionaly, the *patio band* is one more step in the enrichment of the historical evolution of the outside of houses.

3.2 The Bioclimatic Container, BC

The container is the result of a “two folded” process, both material and immaterial. The material fold comes from the land; the inmaterial fold, from the sky (figure 3).

The material fold is opaque and heavy; its climatic responsibilities concern the protection from solar radiation; it also works as a partition wall, structural support and services. It’s composed of three main bioclimatics elements:

- the *Rampart* -a thick services wall-, responsible for the protection of horizontal plans in the inhabited objects, conducting the breeze inside of the objects, previously cooled by evaporative cooling;
- the *Ying-Yang ground-floor* composed by an inorganic ribbon to keep interior temperature at low value, and an organic ribbon to minimize the reflection of solar radiation and cooling the outdoor air;
- the *Green Wall* responsible of protecting vertical plans in the inhabited objects, conducting and cooling the breeze lengthwise, which has both a physical and psychological effect.

The inmaterial fold is permeable and light; its climatic responsibilities concern the protection from solar radiation, regulating ligth and ventilation; it also works for security purposes and landscape visuals. It’s composed of two main bioclimatics elements:

- the *Bioclimatic Geometrical Roof* defined by:

heliosurfaces, protecting from solar radiation the roof of the objects and its openings, and generating electricity and hot water; they are thin to avoid storing heat, and built with oferrocemento; they support a photovoltaic system and solar collectors; the photovoltaic cells (11.2m^2) generates 960w, enough to activate the air extractors installed in the eolic chimneys and to illuminate the tresholds; the solar collectors (8m^2) produces enough energy to heat a 4001iter reservoir;

wind points or eolic chimneys, collecting the breeze for natural ventilation of the inhabited objects; are white and built with insulating material; they work together with the green lines, which help to lower the air temperature; and

green lines, protecting from solar radiation by an evaporative-transpiration process, and regulating light by filtering, and ventilation; they are really a wire cable structure, covered with a green surface controlling solar radiation through absortion, reflection and transmission, lowering air temperature through evapotranspiration;

- the *Threshold* responsible for regulating light and ventilation; it defines the entries to the contained dwelling; a vertical frame works for security purposes and landscape visuals.

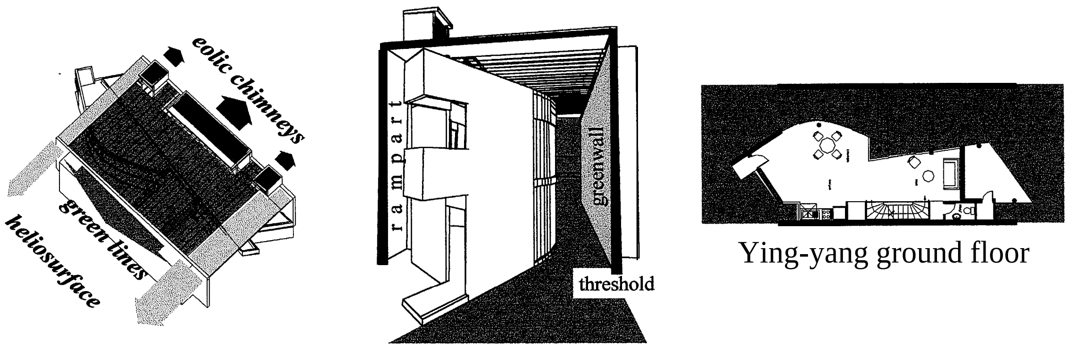

Figure 3: The Bioclimatic Container.

3.2.1 Thermal evaluation

In order to determine the efficiency of the container we analysed two buildings, one with the container and the other without the container, using the meteorological data of the station based in Maracaibo's international airport.

The average values of the last ten years were plotted in a psychrometric chart, in order to examine the relationships between the comfort ventilation zone and the design strategies. The results showed for the whole year that the daily values were inside of the comfort ventilation zone, excepting at noon and at the beginning of the afternoon, when they were located in the mechanical cooling and conventional dehumidification zone.

The study was carried out with the CASAMO-CLIM program [3]; we simulated best (January) and worst (August) climatic conditions, considering the internal charges generated by a family of four people, home appliance equipment and home lights.

The comfort data used to determine the index of satisfied people taken as reference, was a maximum comfort temperature of 30°C with a wind speed of 2m/s as was proposed by Givoni [4] for developing countries.

For the analysis we also assumed three different building operation alternatives:

- opening windows and eolic chimneys to permit air movement;
- closing the openings in the morning to maintain low night temperatures and moving the air with fans for comfort, and opening windows and eolic chimneys at night to permit air movement;
- using mechanical cooling at differents times of the day.

3.2.1.1 Results

The simulations carried out have shown for the best alternative, that the bioclimatic container can lower the inside temperature 4°C, in relation to outdoor temperature. The presence of the container diminish in all the alternatives the difference between maximum and minimum temperatures. The results of the analysis are shown summarized in table 1 and figures 4 to 8.

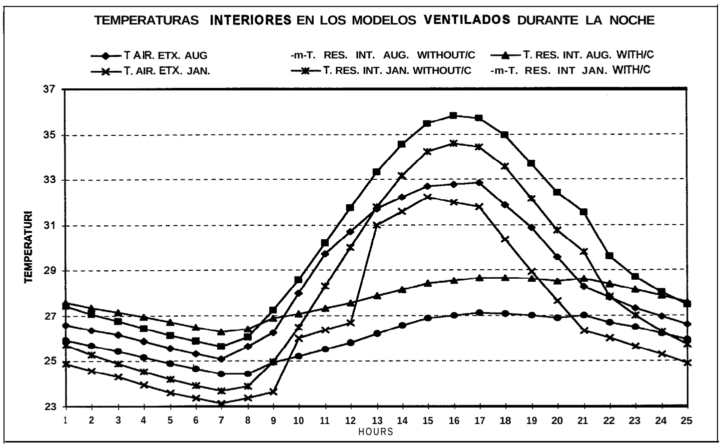

Figure 5: The inside temperatures in both models ventilating at night.

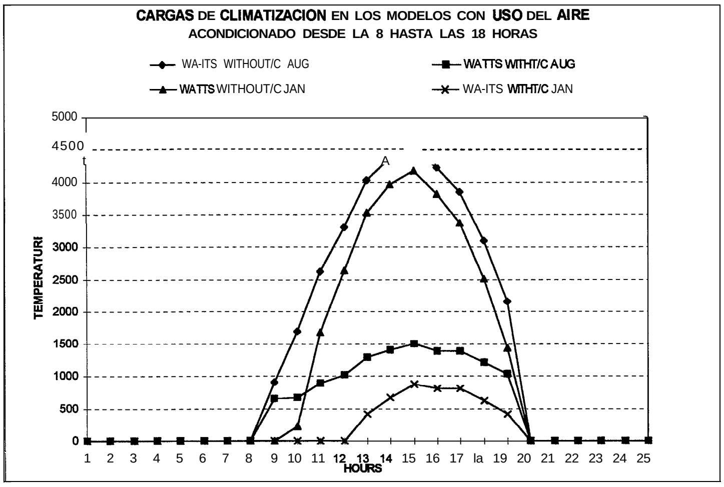

Figure 6: Conditioning charges in both models using mechanical cooling from 8am to 6pm.

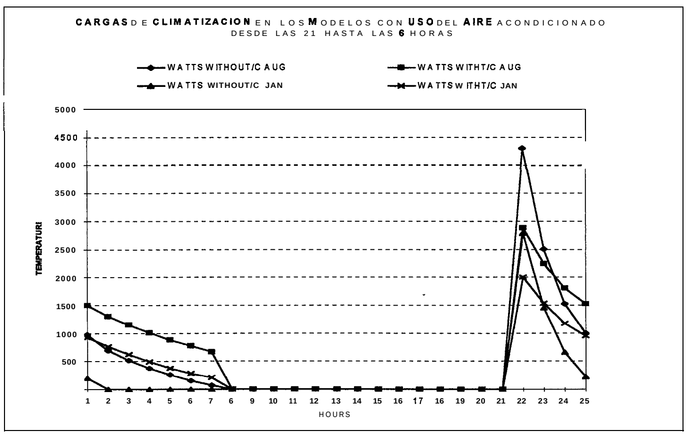

Figure 7: Conditioning charges in both models using mechanical cooling from 8am to 6pm.

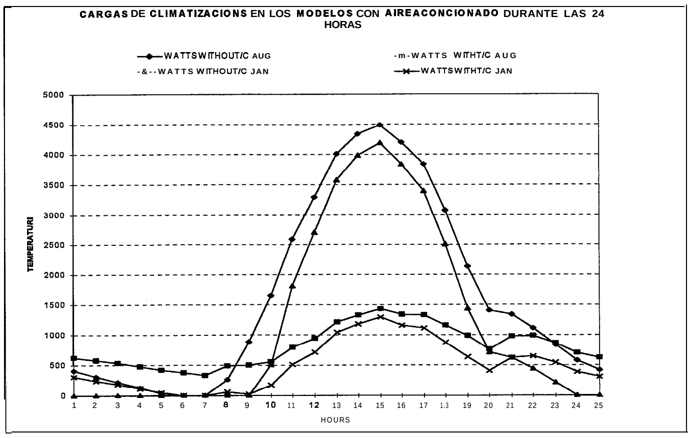

Figure 8: The inside temperatures in both models using mechanical cooling during 24 hours at day.

4 Conclusions

According to the simulations outputs, we determined the effectiveness of the model with the container to diminish air temperature and maintain thermal inside of the house, and also to diminish the climatization energy charges, in spite of registering a higher energy consumption in the mechanical cooling alternative from the 9pm to 6am: anyway, Maracaibo's psychrometric chart shows that the mechanical cooling is required at noon and at the beginning of the afternoon, while at night-time we can be in comfort using only natural ventilation.

The review of the three bioclimatical envelope models existing in the region has permitted the development of a new model: the BC, that incorporates the experience of the three previous models, integrating contemporary technology with tradition. The palafitic notion of *filtering envelope*, the *thick envelope* of the colonial-republican house and the *hat envelope* of the oil company house have been considered and reformulated in the Fourth House -a self contained house-, creating a bioclimatic container with low technology, improving the inside comfort.

A graphic method to evaluate shading effectiveness in windows and facades

C. Quirós
Instituto de Investigaciones de la Facultad de Arquitectura
La Universidad del Zulia, Maracaibo, Venezuela

Abstract
The shading effectiveness of solar protections is determined by the percentual comparison of the shade area projected in the opening or facade, in relation to the total area of the unprotected window or facade. This study proposes a graphic tool to quantify the efficiency of solar control strategies of the openings and building facades for the shade elements proposed in an intertropical locality, in order to establish suitable prototypes according to different orientations.

The shading masks that are used for the evaluation and design of solar protection systems, permits to obtain a value, which would indicate its effectiveness, due to the fact that projections from shade devices obtained from the sunpaths in the celestial vault, don't correspond for all the points of the opening; but generally for the middle point (50% effectiveness) and or extremes of the base of the window (100% effectiveness).

Considering the limitations mentioned above, the shadow effectiveness protactor is proposed, which is based on the principles of the shading masks applied to multiple reference points obtained in the opening or facade surface, with an established percentage. **Taking** as starting point the shading mask of each prototype, effectiveness isolines were drawn (from 0 to 100%), through which the sunshine conditions of the window or facade for any moment of the day and year can quickly be determined.

The shadow effectiveness protactor for openings or facades constitutes a tool that permits its direct application in the design of buildings since it uses a solar diagram as base point, which is very common in the studies of insolation in architecture. The instrument can be as accurate as is required, through the incorporation of reference lines corresponding to intermediate percentages of effectiveness and it is also applicable in cases located in any latitude, using the appropiate solar chart.
Keywords: Solar control, building envelope, energy in buildings, thermal comfort, design tools.

1 Introduction

The effectiveness of the solar protections from the point of view of the shading of the openings and of the facades of the buildings, is intimately related to its efficiency in the control of the incidence of the direct solar radiation. This is determined by the comparison among the area of projected shadows on the window or facade surface considered by the solar protection devices, with respect to the total area of the window or unprotected facade, expressed in the form of index or of percentage [1]. The average of the hourly amounts obtained for a given direction, corresponds to the effectiveness of the system for the stipulated date.

The calculation of the factors and or percentages of shading effectiveness with a high degree of precision, can be by an analytical or graphical method, through numerical processing in worksheets, graph simulation of the shadow paterns in facade and the calculation of the shadowed area in the opening produced by the solar protection through Autocad or other computerized programs elaborated for such means, such as CODYBA version 5.0 [2]. Other programs exist in the market, such as AutoVision, Accurender, ArchiCad, 3D StudioVis, etc. that permit to accomplish the simulation of the effects of the insolation, but don't permit the quantification of the efficiency of the shade elements.

The calculation of the effectiveness of a solar control device as compared to the direct solar radiation, using tabular data and / or the drawing of the standards of the shading, is dificult, laborious and slow that escapes to the ordinary labor of the architect. Considering these disadvantages and limitations, together with the inavailability in tropical developing countries, of specialized programs that permit these calculations, in this work is presented a versatile graph tool: the effectiveness shading protactor. This is based on the representation principle of the shade masks of the solar obstructions and permmits to determine the percentage of effectiveness in an single reading and with sufficient approximation for any direction, hour and date of the year, reasons by which it can be of great usefulness for the architectect and engineer. These effectiveness protactors, are used in an analogous way to the graphs used to determine the shadow angles and direct solar radiation for facades [3].

2. Methodology

2.1 Determination of effectiveness isolines on the surface of the opening or facade.

The isolines of effectiveness constitute geometric places of the points of the surface of the opening that have the same percentage of efficiency shading before the existence of a given solar obstruction. These lines are obtained as the representation from a series of shadows generated by the protective element on the surface of the window, which are characterized by having the same coverage area, taking as reference the shadow projected by the ends of the protection, in frontal vertical projection view.

The isolines are fictitious path lines of the shadows projected by the ends of the element of solar control that correspond to a given percentage of effectiveness. In the case of an overhang, the equal efficiency lines constitute parabolic configuration curves whose extreme points superior (A) and inferior (B) define respectively, a square or rectangular shadow - according to the proportions of the opening- and triangular areas which are equivalent to the percentage of stipulated window surface covered. The intermediate points of the isolines generate a series of shadows in a trapezoidal shape equivalent in surface area, which can be traced through the use of computer drawing programs of great precision such as Autocad. See Figure 1.

It is important to point out that the shadows that are projected outside of the opening (B'), but whose address coincides with one of the inferior extreme points of the opening (B), will always generate the same form and dimension of the shadow on the surface of the window. See Figure 1. In this case, the reference will be the frontal vertical shadow angle that defines that plane that contains all the solar beams that divide the window according to the stipulated proportion.

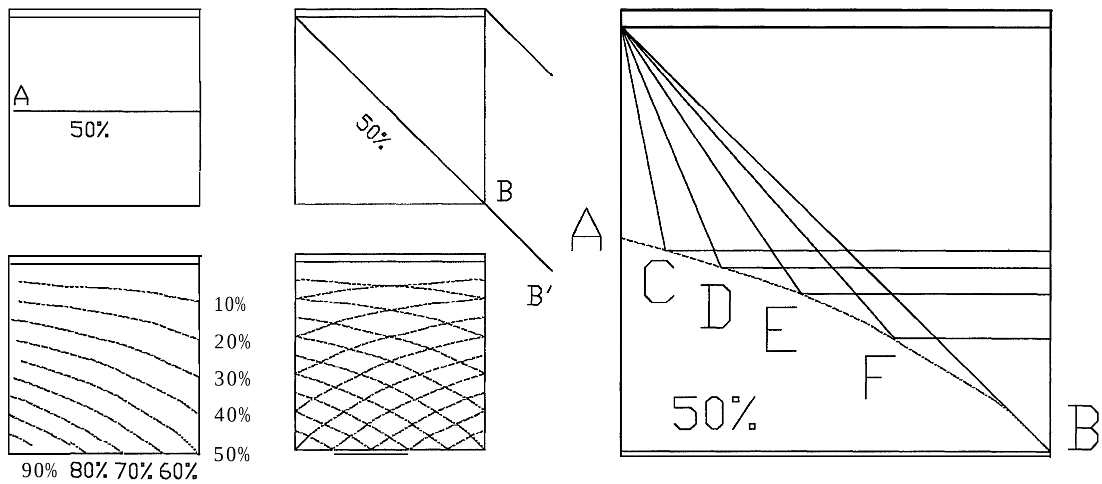

Figure 1.- Determination of the effectiveness isolines generated by a horizontal shade element for an opening

What is previously explained in the representation of the isolines of effectiveness for the particular case of the openings is valid in application to other scales, as in the case of the facades of the building, where solar protection devices exist or adjacent architectural volumes exist that generate shadows, such as is shown in Figure 2.

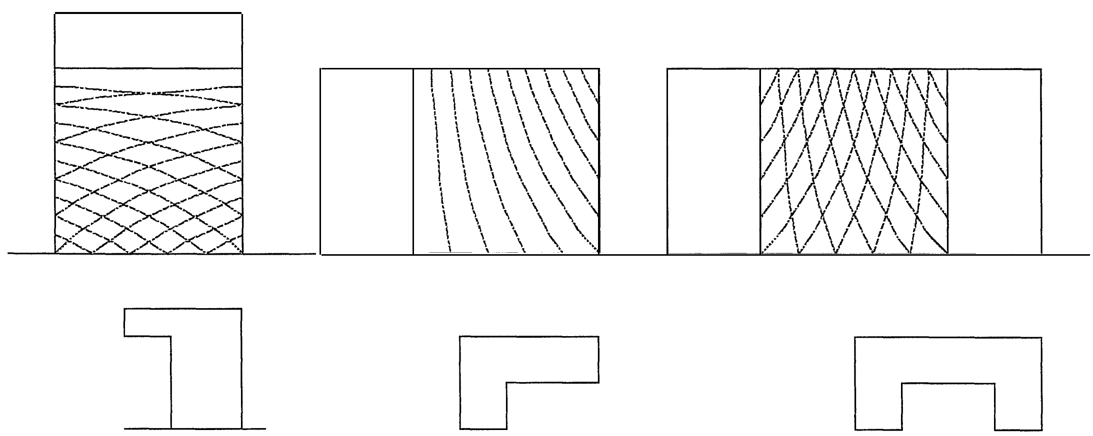

Figure 2.- Isolines of shadow effectiveness generated by superior and lateral volumes that project shadows on the surface of the facades

2.2 Geometric spatial - conception of the shadow effectiveness protactor.
The shading masks of the solar protection systems traditionally are built projecting toward the celestial vault opaque devices of one (< 100% effectiveness) or two points of view (100% of effectiveness) located in the extreme inferior of the opening that will be protected [4]. In our case, to determine the hemispheric projection of the isolines of effectiveness - obtained in the shadow receiving surfaces -, it is required to determine several observation points located on each one of the equal effectiveness lines, as of those which are traced visuals taking as direction the extreme(s) of the solar protection until it intersects with the celestial sphere. Thereinafter, the celestial isolines obtained to be projected stereografically on the horizon plane, generate the effectiveness protactor for the shading.

This graphic protactor constitutes a multiple projection system of solar protections obtained from the celestial vault from each one of the points that describes the different isolines. In this process, several series are obtained from superposed shading masks which upon joining them, generate at the same time, isolines that permit to establish the percentage of protection effectiveness of the opening or in its defect, the percentage of direct solar radiation that the surface of the opening receives for the stipulated solar protection, according to the established ranges (for example, increases of 10%).

In the case of overhangs, the system of isolines traced on the protactor generates a structure in concentric and symmetrical form. The lowest levels of effectiveness in the projection of the shadow, responds to an almost semicircular curve that when it goes through the lengthening and compressing processes the efficiency range is increased until defining a rectiline (for 100%). In the case of vertical elements it adopts a predominantly radial and symmetrical structure, except for the isolines of the highest levels of those which effectiveness become semiconcentrics. See Figure 3.

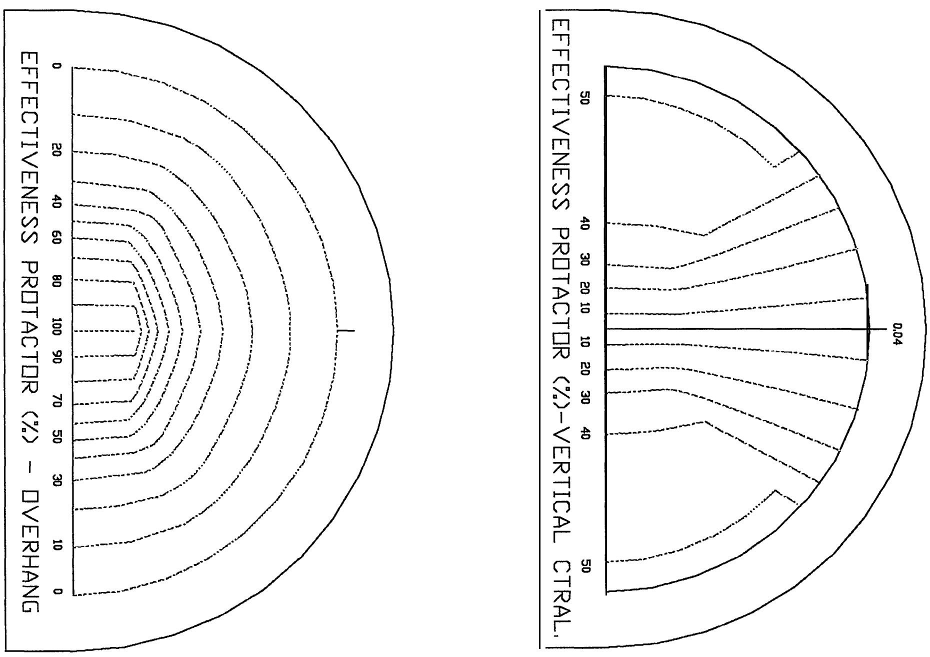

Figure 3.- Effectiveness protactor for a horizontal (left) and a vertical central solar protection (right) equivalent to the 50% of the surface of a squared configuration window.

2.3. **Tracing of the effectiveness protactor from the analytical calculation of the points of the isolines.**

Continuing the previous considerations and appealing to the principles of trigonometry applied to the incident solar beam and to the shadow generated by the extreme points of the protective element, the coordinates of a fictitious sun whose apparent movement will describe in facade the isoline corresponding to the percentage of stipulated effectiveness can be determined, in function of the solar altitude angles and of the horizontal shadow angle. With these two coordinates can be established the position of the apparent sun in the celestial vault and the shadow thrown by one of the extremes of the solar protection element. In Figures 4 and 5 are illustrated the different angles and dimensions to consider in the case of an overhang and a vertical device in a central position.

Using equations that result from applying spherical and flat trigonometry to the solar beam, taking as reference the corresponding plans of the horizon of the place[5], of the facade of the building [6] and of the solar protection, can be obtained the intermediate reference points (C, D, E, F...) that permit the tracing of the isoline on the window as well as in the protactor. The coordinate system of each point is defined by frontal, lateral and horizontal angles of shadow and the solar incidence angle on the facade. See Figures 4 to 6.

Below are presented the data and the analytical expressions that were used for the setup of the worksheets of the angles and projected shades.(See the nomenclature at the end of the work)

2.3.1. Data:

g, B, As, HSA

2.3.2. Unknown:

1) For horizontal shade elements:

$$d = g / \cos HSA \qquad (1)$$

$$xs = d \text{ sen } HSA \qquad (2)$$

$$b = B - xs \qquad (3)$$

$$ys = 2A / (B + b) \qquad (4)$$

2) For vertical shade Elements:

$$d = g / \cos HSA \qquad (1)$$

$$b = 2 As / (g + \text{sen } HSA - B) \qquad (5)$$

$$ys = B - b \qquad (6)$$

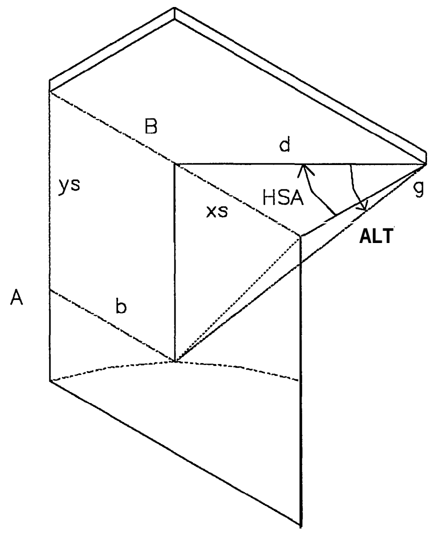

Figure 4.- Angle relationships among the solar horizontal protection elements and the shadows projected in the surface of the window.

3) For isolines representation:

ALT = Atan (ys / d) (7)

FSA = Atan (cos ALT sen HSA) (8)

FSACAD = 180º + FSA (9)
(if FSA is negative)

FSACAD = 360" - FSA (10)
(if FSA is positive)

INC = Acos (cos HSA cos ALT) (11)

S = g tan INC (12)

4) For protactor isolines representation:

LSA = Atan (tan ALT cos HSA) (13)

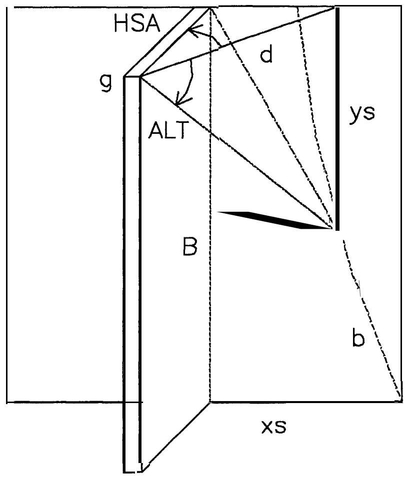

Figure 5.- Angle relationships among the solar vertical protection elements and the shadows projected in the surface of the window

In the cases of solar protections that are located in a central position on the surface of the opening, as in the prototype of a vertical element, we will consider within the shadow area to calculate, the thickness of the same protection element that, in the case of the overhangs, was not taken into account by virtue of the fact that they were located outside of the surface of the window. Because of this, for example, in the vertical protection the horizontal extreme shade for an effectiveness of 50% will not divide exactly by half the openings to protect, but at a smaller distance; while for an extreme oblique shadow in the order of 50%, generates a trapezoidal configuration instead of triangular. See figure 7.

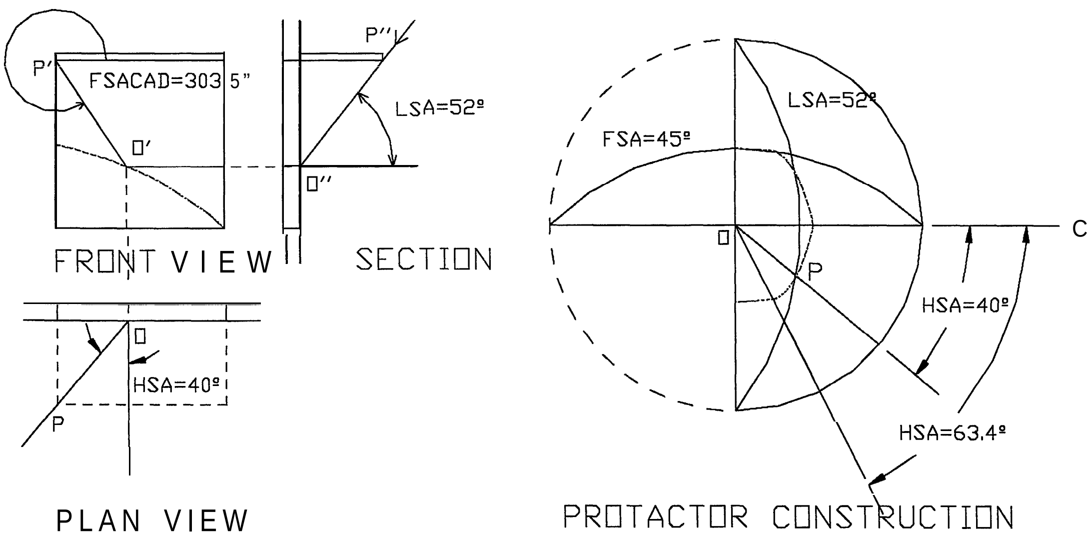

Figure 6.- Required shadow angles and traced of the isolines in the effectiveness protactor.

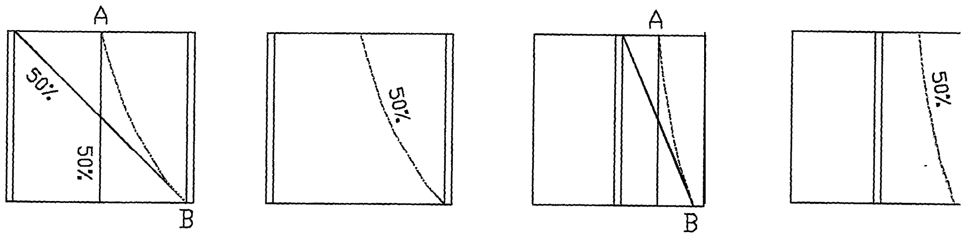

Figure 7.- Effectiveness isolines in the shading of the opening for a central and lateral vertical protections.

3 Discussion

It is evident that for each solar protection system to consider, there will exist a design for its respective effectiveness protactor, something which supposes a moderately laborious task, compared with the simulation method graph. Once its representation is obtained, it will permit the evaluation of infinite cases attending any direction of the window, hour, date of the year and latitude (using the corresponding solar diagram).

Because in Autocad, the representation process graph and the calculation is very slow, for the elaboration of the effectiveness protactor manually, a computerized program designed for this will be required, handling the Lisp language, in the same Cad package.

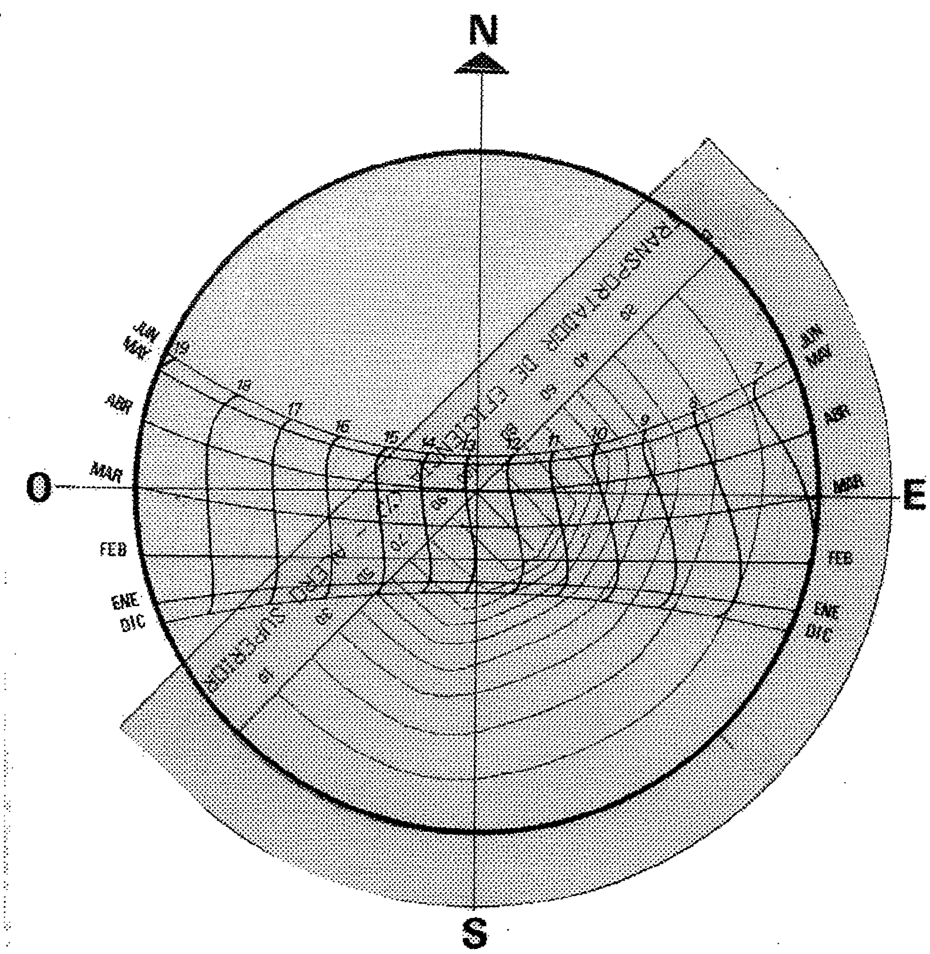

Figure 8.- Assembly of the effectiveness protactor with the stereographic solar graph for the study of an opening with direction southeast.

4 Conclusions

l)The effectiveness protactor in the openings shading constitutes a tool that permits its direct application in the architectural design since it uses as base a solar diagram, very common in the studies of insolation.

2) The overlapping of the isolines of the protactor with the reference lines for the different apparent solar paths, permits to quantify with good approximation the value of the hourly effectiveness of a solar protector. See Figure 8

3) These tools can be applied in scale models, to evaluate the insolation conditions in facades and or roofs, two-dimensional devices of solar protection for facades, or volumetric studies for the purpose of shading.

Abstract

The prevalence of observations of moisture or mold was surveyed in 240 apartments and the health status of the occupants was surveyed with a questionnaire. A random sample of 120 apartment buildings were taken from the building registers of three cities. The buildings and two apartments from each were carefully walked through and all the signs of moisture and mold recorded. The occupants of the apartments and the house manager were also interviewed for their observations and the damage and repair history of the building. The field study was made using questionnaires and checking lists by civil engineers, trained for the standardized procedure. Before the visit of the surveyor, a health questionnaire was sent to the occupants of the apartments studied. In 60% of the apartments, signs of current or previous moisture damage could be observed. Part of the faults had been repaired, but 42% of the apartments were assessed to be in need of repair because of the moisture observations. Signs of moisture were observed in nearly all the facilities in common use (97%). Respiratory symptoms, such as cough, nocturnal cough and dyspnea, sore throat, hoarseness, rhinitis, nasal bleeding and impaired sense of smell were significantly associated with the observations of moisture, as well as sinusitis (OR=2.58). When the exposure was defined as mold present (either visible mold or odor of mold), the association was significant for several symptoms and respiratory infections:common cold, sinusitis and bronchitis. The results show the health-based importance of good maintenance.
Keywords: Apartement house, moisture,mold, exposure, health effects

1 Introduction

Many factors can lower the air quality in homes. Typical sources for indoor air pollution are tobacco smoking (respirable particles, CO, VOC), gas stoves (NO, , CO) or woodstoves and fireplaces (CO, PAH). Also building materials (formaldehyde, radon), earth underlying the home (radon) and moist materials and surfaces (biological agents) can lower the indoor air quality [1]. Dampness, condensation or moisture causing permanent or intermittent wetting of materials may cause growth of molds, bacteria and rot fungi. In buildings, this microbial growth may damage buildings and lower the quality of indoor air.

The principal factors causing dampness can be leaks in ceilings, walls, windows, roofs or piping. Also lack of design or work, wrong construction methods, aging of materials and heat leak may cause moisture damages in buildings [2]. Dampness and mold growth in dwellings have been associated to a number of respiratory health effects [3],[4]. Since excess moisture in structure is the main factor which permits growth of these microorganism, observations of dampness and moisture can be used as a proxy of indoor microbial problem and subsequent exposure to microbial emissions [5]

The aim of this study was to determine the prevalence of moisture problems in the apartement buildings in Finland and possible association between mould or moisture problem homes and respiratory symptoms among a randomly selected population living in the apartement buildings.

2 Material and methods

2.1 Buildings and apartments

A random sample of 120 apartment buildings and two apartments from each building, that is 240 apartments in all, were randomly selected from the building registers of three cities. In each city equal sample size was selected from the buildings erected in the 1950's,1960's, 1970's and 1980's. Simple random sampling was used. These cities were Helsinki (population circa 500 000), Kuopio (population circa 83 000) and Oulu (population circa 100 000). A civil engineer, specially trained for this purpose, made a thorough walk through in the apartments and in the corridors, laundry, sauna and storage rooms that were in common use of the occupants. The roof, envelope and basement of the buildings were also examined. All the signs of moisture or moisture repair were recorded. Visual observations were confirmed with surface moisture recorders. In addition to this, the occupants and the house managers were interviewed for their observations and the damage and use history of the building. Moisture problems were graded into classes 0 to 5 according to their estimated severity:

- Class 0: No damages, or damages were repaired.
- Class 1: Only surface materials were wetted. Moisture has extracted by evaporating and drying.
- Class 2: Surfacing was detached, structures have to be dried and reglued or repainted.
- Class 3: Surface materials or structures, for example carpets or flagging have to be removed, base floor or roof opened and dried.
- Class 4: Whole elements of structures, such as supporting walls or basement floors, have to be removed.
- Class 5: Building is irreparable and purpose of use is unsuitable.

In those cases where there were more than one observation of moisture, the apartment was classified according to the most severe moisture damage.

2.2 Occupants of the apartments

Health questionnaires were sent to each individual living in these apartments. The occupants were divided into three categories according to their age. Each category had their own questionnaire. The categories were: children under seven years old (small children), children between 7 and 15 years old (school children) and people who were 16 or older (adults).

Questionnaires were sent before the civil engineer's examination. Questionnaires were turned in to the civil engineer, when he arrived to the apartment to make a walk through. All together 385 (3 18 adults, 27 schoolchildren and 40 little children) questionnaires were returned. Out of 3 18 questionnaire 188 were from separate apartments. That is at least one adult returned a questionnaire in 78% (82.5% in Kuopio, 85.0% in Oulu and 67.5% in Helsinki) of all the apartments.

2.3 Exposure

Exposure was defined in two different ways. Exposure to molds was defined according to occupants observations. If the occupant knew visible mold or had smelled the smell of mold or like, then the apartement was defined as moldy. Exposure to moisture was defined according to civil engineers observations.

2.4 Statistical methods

Prevalence of respiratory symptoms and infections between exposed and non-exposed groups were compared with multivariate logistic regression. Potential confounders for the health effects were included in the model. In these analysis age, gender, allergy and pets indoors were considered as confounders. Odds ratios were calculated as well as 95% confidence intervals (CI) for the point estimates of the exposure variables. SAS (Statistical Analysis System) software was used (SAS 6.09 for Alpha) [6].

3 Results

3.1 Buildings

In 60% of the apartements there were at least one sign of moisture present. This is a little less than the same figure of the single-family houses [7]. These figures include all the moisture problems, also those which had already been prepared. 12% of the moisture problems were graded into class 1, 45% into class 2 and 43% into class 3. There were no damages in classes four or five in these apartements. In all, 42% of the apartements were in need either a repair or more specific examination while the same figure in the single-family houses was 55%. Most moisture problems were in apartements built in 1950's and in 1970's and least in 1960's.

In this study rooms were divided into three categories: moist rooms (bathrooms, saunas, laundry rooms etc.), kitchen and other facilities (hall, living room, bedroom etc.). Most problems were in moist rooms. In 36% of the moist rooms that were studied a moisture problem was found (Figure 1).

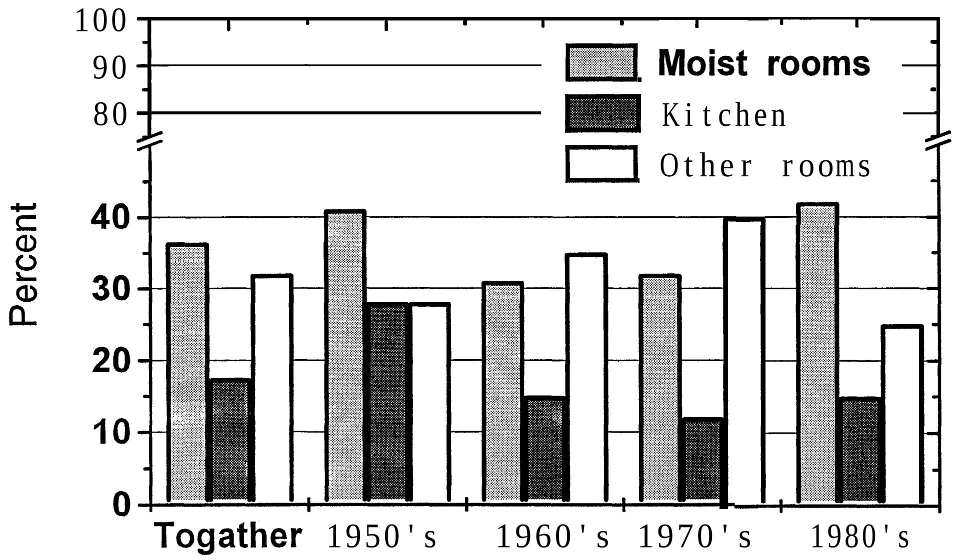

Figure 1. Moisture problems in percents in different facilities in different decades in apartement houses.

3.2 Exposure to molds

A total of 22 health outcomes were studied. For 19 health outcomes the proportion of those with the illness was higher in the exposed adults than respective non-exposed individuals (Table 1). Out of these 19 outcomes 9 symptoms were statistically significant.

Table 1. The proportions of the occupants with respiratory or non-respiratory illnesses and adjusted odds ratios for the association between mold at home and no mold at home in the past 12 months.

	Mold Absent	Mold Present		
Infection or symptom	l-l (%)	n (%)	OR	95% CI
Common cold	165 (64)	46 (84)**	2.34	1.03-5.33
Tonsillitis	10 (4)	5 (9)	2.49	0.76-8.15

Allergic eczema	22 (14)	12 (9)	0.52	0.22-1.21
Eye irritation	63 (39)	64 (47)	1.49	0.88-2.5 1
Nausea	43 (32)	50 (42)	1.36	0.77-2.41
Headache	114 (77)	104 (82)	0.94	0.48-l .83
Fatigue	138 (90)	124 (95)	1.85	0.65-5.23
Difficulties in concentration	55 (41)	58 (48)	1.16	0.68-1.97

* p <0.05, ** p co.01

Odds Ratios adjusted for smoking, age, gender, allergy, pets indoors and atopic predisposition. The number of occupants in exposed group was 143 and in non-exposed it was 172.

4 Discussion

In 60% of apartements, signs of current or previous moisture damage could be observed. Part of the faults had been repaired, but 42% of the apartements were assessed to be in need of repair because of the moisture observations. The highest prevalence of moisture observations was found in the apartements built in 1950's and in 1970's. There were faults in both ceilings, walls, windows, roofs and pipings. In the facilities in common use, signs of moisture could be observed in nearly all the buildings (97%). Most faults were in the floor and wall structures of laundry rooms, saunas and storage rooms. Every second building had roof leakages or damage in the outer envelope. The most important causes for the faults originated from the time the building was erected, as mistakes in design or work; other causes were aging of materials and faults in the insulation.

Good maintenance of buildings is crucial in control, preventation and early detection of moisture problems. The health effects are caused by the emissions from microbial growth in building structures with excess moisture. Microbial growth in apartements should be considered a health risk and the moisture causing the growth should be repaired. Air outsets between the basement facilities and the apartements above them allows emissions to penetrate into the indoor breathing air of occupants.

DESIGN FOR HEALTH
Healthy Building Project

Roger Corner
Environment and Health Protection Administration, The City of Stockholm, Sweden

Abstract
In an effort to come to grips with health problems, in particular the Sick Building Syndrome (SBS), related to many newly and rebuilt housing estates, the Environmental Administration has initiated a joint project, together with a builder - Stockholmshem. This **healthy building** project is part of a general allergy campaign in Stockholm. In conjunction with the project design of a new housing estate, Mandeln, consisting of three building blocks with 6-8 levels and 114 apartments, a **Health- and Enviornment Program** has been put forward. The program prioritizes questions of indoor climate for healthy buildings with particular emphasis upon moisture control, emissions from materials and constructions, ventilation, noise and energy balance. A series of quantitatively verifiable **performance standards** is presented, and IAQ measurements and questionaires will be carried out after construction in a reference apartment and in four other occupied apartments.
In the program an effort is made to relate standards for healthy buildings to certain elements and guidelines for resourceful and environmentally adapted buildings. For example certain environmental controls of materials, energy economizing and waste treatment.
The project has also highlighted the necessity to systematically choose environmentally adapted and healthy building materials based upon clearly defined health and environmental criteria. A discussion is now taking place to develope a transparent system of ***Environmental Criteria for Building materials*** for the city of Stockholm (SMB). It is hoped this will enable builders and others to make conscious environmental decisions when choosing building materials in newly and rebuilt building projects.

Key words: Building design, materials and construction, moisure control, guidelines for health and environment, quality control, housing estate

INTRODUCTION AND AIMS

Together with a builder -Stockholmshem - the Environmental Administration of Stockholm has initiated a **healthy building** project. The aims of the project are:

- Follow and take part in the planning, building and evaluation of re-built and newly built housings estates, where the construction, installations and building materials have been chosen with special care so as to obtain a good indoor environment for the tenants.
- Gain more knowledge and experience of how healthy buildings can be constructed in practise.
- Put forward “good examples”.
- Relate healthy buildings to the on-going process and discussion of resourceful and environmentally adapted buildings (sustainable buildings).

Quality criteria for healthy buildings will be developed on a joint basis within the framework of the project. These can vary depending upon the buildings location and requirements.

The building process is a complicated planned process with many different disciplines and parameters involved, indoor- and outdoor environment, quality control, time and economy. During the last few years there has been a shift in Sweden from governmental and local council steering to increased self control by builders. Experience from building projects during the 80:s and increasing enviromental consciousness are also important factors in the changing preconditions for the building process. It is imperative that the development of systems of quality control and enviromental aspects (e.g. IS0 9001, 14001, etc) are integrated into the building process at early stages and are followed through during the buildings use.

METHODS

To date we do not have any clear scientific models capable of explaining the multitude of effects and causes involved in health problems related to buildings, especially SBS. The author maintains, however, that these health problems can be prevented in modern housing estates by correct design, an integrated approach to quality control and enivironmental aspects including clear guidelines, and consideration of or direct involvement of tenants. For this to take place it is necessary for working project groups to discuss and put forward health and environmental issues, and for the project leader/builder responsible to see that the necessary competence and quality control procedures are present and applied throughout the whole building process.

In conjunction with the project design of a new housing estate, Mandeln in the city of Stockholm, a **Health- and Environment Program,** including a series of guidelines,

has been presented and discussed within the framework of the working project group. The program puts forward both qualitative and quantitative goals and prioritises questions of indoor climate for healthy buildings with particular emphasis upon moisture control, emissions from building material and constructions, ventilation, sound and energy balance. Questions related to resource effective and environmentally adapted - sustainable buildings - are also put forward. The program is a reference standard together with the builders present standards and environmental policy, The City of Stockholms Enviormental Program, the Cities planning documents and complementary quality program and Environmental Manuals.
Construction of the Mandeln estate will begin in October 1997. The author will follow the building project through all stages and an evaluation and report will be made later.

A program for IAQ measurements will be carried out, in a sample apartment without tenants and four other normal apartments. A questionaire put out to the tenants about one year after construction during the heating season will also be evaluated.

A system of criteria for choosing environmentally adapted building materials is also under discussion.

PRESENTATION OF THE HEALTH- AND ENVIRONMENT PROGRAM

The program is project specific for the Mandeln estate and will be modified and revised later for more general use. The program consists of general and specific aims and includes quantitative standards for the indoor environment. Only a general outline can be presented in this paper.

Building construction and materials

It is necessary to plan for low emissions and healthy building materials in the structure, surface layers, interior fittings and installations. Such a plan should include the following:

- The chemical declaration of building products including additives, from both health and environmental aspects. The builder should consult chemical expertis. The moisture- and pH levels the materials can withstand in the surrounding construction should also be considered, ($pH_{accept} < pH_{critical} - \Delta pH_{safety}$)
- A risk evaluation of which pollutants are likely to be emitted to the indoor air from the building products and constructions.
- Smoothing compounds should have low alkalinity and not contain Portland cement.
- Measurement of emissions (VOC) from certain building surfaces after construction, before tenants move in, using FLEC (The Field and Laboratory Emission Cell) in a comparatve manner.

A plan for moisture control and dimensioning for the main construction components should be made and include as a minimum:

- Moisture characteristics and effects of building materials and construction.
- Acceptable moisture conditions and levels set in relation to critical construction damp levels and safety factors - e g higher pH in concrete with higher water/cement ratio, glueing techniques, surface pore-structure etc ($RH_{accept} < RH_{critical} - \Delta RH_{safe}$). RH 85% is suggested for normal cement floor structures.
- Acceptable and standardized damp measurements, the measured values should be less than the guideline value, including consideration of maximum variation, before laying floor coverings.

Guidelines for environmental control of materials in the construction:

- Materials and constructions with long durability should be chosen, and which can easily be dismantled and re-used.
- Emphasis should be put upon resource effective materials and usage without environmentally dangerous or disturbing substances.
- Materials containing PVC should be avoided where possible.
- Wood from tropical forests should not be used.
- Copper should not be used on roofs, outer walls and pipes as far as possible. Zinc roofing should also be avoided.

Ventilation and indoor climate

Guidelines and specifications for thermal climate, indoor air quality:

- The building should be well insulated and airtight.
- Sources of increased temperature should be taken into account when designing the building, e.g. windows facing south, etc.
- Cold surfaces should be avoided, and there should be no leakages in the building envelope.
- Outdoor air is preferably taken from the northern side of the building where possible.
- Air flows should be determined in relation to maximium moisture levels and temperature in the building,
- Outdoor pollutants should determine the position of intake air vents.
- There should not be any accidental return of exhaust air.
- Good air exchange rates and cirulation so that intake air is distributed to where people are.
- There should be possiblities for re-distribution of intake air, especially to bedrooms during the night.
- Microbiological growth in ventilation ducts should be avoided, and good cleaning possibilities should exist.

- Dry constructions and materials with low emissions and neutral odour should prevail.
- Informative and easily understandable instructions to tenants - of how they can effect and keep clean the ventilation.

Guidelines and specifications for sound and light:

- Sound-transmission class B according to the newly established Swedish Building Standard (SS 025267). This is better than class C, the minimum level for modern Swedish houses, but not as good as class A.
- Structure-born sound should be reduced to a minimum with appropriate sound insulation materials and constructions.
- Impact sound-reduction is considered important, particularly for floor surface layers.
- Components between floor structure and walls are important feactures to consider when sound insulating.
- Reduction of low and high frequency sounds should be of special concern when sound-proofing.
- Low level pressure decreases in the ventilation give both low sound and better effect.
- Three-way or equivalent two-way windows reduce sound levels and at the same time reduce heating costs.
- Large windows give good daylight but can also be a source of over heating.
- Light colours are considered more appropriate.
- Glaced balconies and verandas should be easy to clean.

Guidelines for electrical installations and energy economizing

- A five wire system for electrical installations.
- Stray currents in water pipes and radiators should be avoided.
- Placing electrical applìences with magnetic fields close to buildings should be avoided.
- Energy effective solutions give better economy and reduce the load on the environment.
- The buildings energy balance is of prime importance as regards both energy costs and indoor climate.
- A calculation of the buildings energy balance should be carried out and comply with The City of Stockholms program for “Energy Effective and Healthy Buildings”.

Waste treatmant

Guidelines for waste treatment should include:

- Possibilities for sorting environmentally hazardous waste and fractions for which there is producer responsibility, preferably within the building.
- Cupboard space for sorting provided for all appartments.
- Sorting of building waste produced during production into appropriate fractions for re-use. Environmentally hazardous and dangerous waste sorted for correct treatment.
- Minimize material wasteage and use returnable packaging during construction.
- Materials and constructions chosen so that dismantling and re-usage is possible.

Building production

A plan of control for low construction damp should include the following:

- A building design which takes into consideration necessary drying-out procedures for different materials and constructions, especially concrete floorings.
- Onsite weather protection of materials, inspection and specified damp and moisture levels before use in the construction. Measurement of relative humidity and temperature.
- Early assembly of roofs and protection of windows and door openings as far as possible.
- Verified construction damp control. Highest values and measurement methods should be specified in building documents for contractors. Inbuilt monitors may be used.
- The building construction should be able to withstand the moisture it will be subjected to in its lifetime.
- A plan for low construction damp should not exclude moisture dimensionering.
- A clean building progam should be developed.

Control of ventilation during and after construction:

- All components should be protected from dust and moisture. Ducts, fans, sound-proofers, vents, etc should keep their protective coverings until assembled.
- The ventilation should not be started until the building has been thoroughly cleaned.
- The ventilation should be in operation and controlled before the first tenants move in.

Quality control

A series of concrete performance standards are put forward for, moisture and emissions from building materials and construction, thermal climate, indoor air quality, ventilation, sound climate and magnetic field. These standards are quantified in an appendix to the program. The levels are above normal minimum Swedish Building Standards, but below those considered necessary for houses totally adapted for tenants with allergies. It is considered that these standards are reasonable preconditions for newly built healthy buildings and should not increase overall building costs. At this level about 85% of the tenants should experience the indoor climate as accepable in a standard questionaire.

To ensure that these aims and levels are followed inspection plans will be carried out, primarily concerning the most critical points which can effect the indoor climate. Control measurements of relevant performance standards will be carried out, and a standard questionaire for indoor climate and health will be carried out about 1 year after completion or before guarantee inspection (after two years).

A series of concrete and verifiable Performance Standards are presented in an appendix to the program. Special attention will be payed to the measurement of initial moisture levels at different depths in several concrete floor structures and at different intervals in time, both before and after laying inner flooring covers. These measurements will be related to theoretically expected values at critical depth (0.20 of structure thickness).

A report evaluating the results from the building project will be made later. A follow-up report is expected to be presented at the next Healthy Building conference in Helsinki, 2000.

Acknowledgements

I would like to thank The City of Stockholm for finansing and making this project possible, and for support from people in the project group, Bengt Kvist and Hans Meckbach, Stockholmshem, Hans Björkman, Municipal Planing and Building Administration, Georgios Tsiroyannis, Stockholms Tennants Association and Gunilla Sallhed and Lasse Iisakka, Environmental Administration. I would also like to specially thank Marie Hult, White Architects for her expert advise and several others for reading and adjusting the text in the program. I also thank Ulla Larsson, Health Director, Department of Health for her help and support.

Indoor environment and health

PARAMETER	LEVEL	COMMENTS
Thermal climate:		
Room temperature	22 ± 2° C	Winter at DOT (3*)
Air speed,occupied zone	0,15 m/s	Normal vent. (BBR) (4*)
	0,20 m/s	Increased ventilation
Floor temperature	18-24° C	Lower air temp. acceptable at higher floor temps.
	20° c	Lowest level in bathroom
Relative Humidity	<75% during summer	Preferably >25% wintertime
Air quality:		
Cooking fumes	Not between apartments	Poss, to increase extract air
Nitrogen oxides	0,05 mg/m^3	Mean value 24h
Formaldehyde	<0,05 mg/m^3	Mean value 8h
Particals in intake air	<20 000 parts./m^3(1-10µm)	After filter
Airbourne particals	60 µm/m^3 (<10µm)	After cleaning&before use
Radon gas level	200 Bq/m^3	(BBR)
Gamma radiation	0,5 µSv/hour	(BBR)
VOC in room air	No unnormal levels of irritants &/or indicaters	Approx 1 year after comple-tion
Ventilation:		(Exhaust system)
Volume exchange-rate	0,6 - 1,0 ACH	Extract volume rate
Carbon dioxide in bedroom	1000 ppm	Winter, higher level accepted
(redistribution to b-rooms)	(10 l/s - for 2 persons)	(BBR, etc)
Air-exchange efficiency	45%	Extra supply-air device
Flexibility:		
Total flow increase	0-50%	In the whole housing block
Redistribution of flow	Partly	Within apartments
Demand controlled vent.	±50%	For whole apartment
Operation & Maintenance:		
Cleaning accessibility	In neutral spaces and some apartments	
Accessibility/supervision	Partly free from the structure	
Periodic maintenance	According to a central plan	
Operating economy:		
Net recovery efficiency	60%	Energy in ventilation air
Specific fan power (SFP)	0,8 kW/m^3/s	Extract ventilation
Degree of insulation	1,5° c	Max temp. decrease vent.air
Sound:	Sound-transmission class B (minimum level for good sound environ-ment, better than normal standard class C) (5*)	
Sound insulation	Including reduction of low frequency noise (6*)	
Outdoor noise	Noise levels in SNVs guidelines are aimed at (7*)	
Electro-magnetic fields:	**(8*)**	
Magnetic field	<0,2 µT	Permanent installations only

(3*) Design Outdoor Temperature
(4*) National Board of Housing, Building & Planing Building Regulations, minimum levels for Swedish houses
(5*) Swedish Standard SS025267, 4 sound-transmission classes are defined A,B,C and D where A is very good sound conditions

Classification of Indoor Climate, Construction, and Finishing Materials

0. Seppänen

Department of Mechanical Engineering, Helsinki University of Technology, Espoo, Finland

Abstract

Good indoor climate is one of the main goals of building design and construction. Studies all over the word have shown that this goal is far too seldom obtained as research results are not applied to the practice.

To overcome this problem of information transfer between research and practice, a design guide for good indoor climate was prepared in Finland. It was done with co-operation between the Finnish Association of Construction Clients, the Finnish Association of Architects, the Finnish Association of Consulting Engineers, and the Finnish Society of Indoor Air Quality and Climate.

The documents consists of three parts: 1) Classification of Indoor Climate, 2) Classification of Construction Cleanliness, and 3) Classification of Finishing Materials. Because requirements for all buildings are not always the same, all the parts present the criteria and requirements on two or three quality levels. The lowest category corresponds to the present building practice set by official building codes. Higher categories present significant improvement in the design and construction for better indoor climate. The construction client selects the categories with the design team at an early stage of a construction project. The classification can be referred to in the building specifications. It can be used in new constructions and in evaluation of old buildings, as well as in renovations.

The Classification of Indoor Climate includes target values for indoor air quality and climate. It also gives the most important design values for heating, ventilation and air-conditioning equipment. The Classification of Construction Cleanliness deals mainly with the principles and procedures to be followed at various stages of construction works. The Classification of Finishing Materials contains limit values for chemical emissions of building materials. In addition, it presents the maximum surface area of materials allowed in a space to obtain the requirements of the selected category of indoor climate.

The Classification is intended to be used during the design and contracting phases of construction works and mechanical systems for buildings. It also gives guidelines to manufacturers of equipment and materials to produce better building products in respect of good indoor climate. The Classification can be used both for new constructions and renovations, and also during the evaluation of buildings.

Keywords: air quality, cleanliness, design values, healthy buildings, indoor climate, material emissions, ventilation

Introduction

Indoor climate has become more important for health and comfort during recent years. As people stay indoors approximately 90% of the time, the quality of indoor air for the health is even more important than outdoor air. Good indoor climate reduces illness and the symptoms of sick building syndrome. It also influences comfort and working efficiency. The costs caused by poor indoor climate in the Finnish building stock has been estimated to be 18 billion Finnish marks per year (app. 3 billion ECU), corresponding to the costs of energy consumption of buildings.

Good indoor climate is one of the most important factors in assessing the quality of a building. Research and practice have, unfortunately, shown that good indoor climate is not always achieved. Indoor climate is influenced simultaneously by several factors, such as heating, ventilation and air conditioning, construction methods and materials, operation, maintenance and use of buildings. The Classification of Indoor Climate, Construction, and Finishing Materials /1/ presents guidelines considering all these factors. It has three parts and is intended to be used in design and construction of buildings and their mechanical systems. It also encourages manufacturers of equipment and materials to produce low-emitting building products.

The Classification of Indoor Climate, Construction, and Finishing Materials was developed by Finnish Society of Indoor Air Quality and Climate (FiSIAQ) based on Finnish and international research results. The work was sponsored by the Finnish Ministry of the Environment.

The Finnish classification

The final quality of indoor climate is influenced simultaneously by heating, ventilating and air-conditioning systems and equipment, by the performance of the construction and materials, and by the operation and maintenance of the building. To achieve a good indoor climate, all the guidelines presented in the Classification need to be taken into account throughout all the phases of design, construction and operation. The Classification has three parts: Part 1, Indoor climate; Part 2, Cleanliness of construction; Part 3, Finishing materials and it is intended to be used during the design and contracting of construction works and mechanical systems for buildings, and in the manufacturing of equipment and materials to build healthier and more comfortable buildings. The Classification can be applied to new buildings and for evaluation of all buildings and, when applicable, also during renovation. The Classification gives target and design values for indoor climate and supports the work of clients, designers, equipment manufacturers, contractors and operation personnel. The Classification can be referred to when writing up specifications of construction and mechanical systems. It can be used even as an attachment to such specifications. The Classification does not overrule official building codes or interpretations of them.

When the ultimate goal is good indoor climate, the best category of each part of the Classification has to be selected. The low category of one part cannot be totally compensated by a high category of another part. Thus, for example, the high emissions of building materials are difficult to be compensated by increasing the ventilation.

Selection of categories

The Classifications of Indoor Climate and Finishing Materials have three categories, and the Classification of Construction Cleanliness two categories. Indoor Climate category S 1, Construction Cleanliness category Pl, and Material category Ml correspond to the best quality. Categories S3, P2 and M3 are in line with the official quality set by building codes and regulations.

The categories for indoor climate, construction cleanliness, and finishing materials shall be selected at an early stage of a construction project. The client selects the categories with the design team. With the help of the Classification of Indoor Climate, the target values for the indoor climate are specified. After this, the category of Construction Cleanliness is selected in accordance with the Classification of Construction Cleanliness. The Classification of Finishing Materials is used when selecting building materials. If necessary, the target values and requirements can be selected from different categories. However, when the ultimate goal is good indoor climate, the best category for each part of the Classification shall be selected. The low category of one part cannot be totally compensated by use of a high category for another part. Thus, for example, the high emissions of building materials are difficult to be compensated by increasing ventilation. So far, it has not been possible to take into account material emissions when selecting airflows for ventilation because the finishing materials have been selected at a late stage of the construction process.

The classification of indoor climate (Part 1)

The Classification of Indoor Climate deals with common work and living spaces (office and public buildings, schools, day-care centers, dwellings, and other buildings of similar type). The Classification has three categories: Categories I, II and III. Category I is the best meaning higher satisfaction with indoor climate and lower level of complaints. For example in respect of room temperature, Category I corresponds to 90% of satisfaction. Category III corresponds to the requirements set by building codes.

Target values

The target values of indoor climate factors (Table 1) are used to specify the target level of indoor climate at an early stage of a building project. The target values can also be used for checking the indoor climate and compliance with the requirements. The target values apply to the zone of occupancy of a room which usually extends from the floor surface up to 1.8 meters from it. It begins 0.6 meters from the walls.

The concentrations of indoor air pollutants presented in Table 1 will not be exceeded in general if the ventilation rates are as high as specified in the tables, and if there are no specific pollutant sources in the room. Thus, the measurement of indoor air pollutants is not generally required.

The Classification does not give limit values for concentration of microbes because the building may have mold damages even if the room air does not contain high concentration of bioaerosoles. The concentration of bioaerosoles may vary strongly depending on time, location, conditions and species of microbes.

Design values

The design values presented in Table 2 should be used specifically in dimensioning of heating and air conditioning equipment. The designer also has to define the conditions where the building conforms to the design values including loads and operation of the room (number of occupants, lighting load, equipment load, etc.) and external loads of a room. Design weather conditions are given in the document, too.

Verification of limit values

The design and limit values of a building should be checked when the building is in operation, in winter when the outdoor temperature is below -5 °C, and in summer when the outdoor temperature is above 20 °C and the weather is clear. The compliance of design and target values in other than design conditions have to be checked with calculations taking into consideration also the capacity of heating and cooling equipment. Design and limit values of indoor climate have to be measured with the instruments which a have calibration certificate.

Classification of cleanliness of construction (Part 2)

The Classification of Cleanliness of Construction gives the requirements for construction and air handling equipment, their installation and use. The extend and level of requirements depend on the category which is aimed at. The Classification has two stages: Category 1 corresponds to the best quality and category 2 to the level of present construction practice. Good indoor air quality provides co-operation between all parties involved in the construction project and the fulfillment of all the requirements given. The requirements are given mainly to contractors but also to designers, equipment manufacturers, and users of the building.

The requirements in category 1 include, for example, the following:

Air handling system and equipment

Ductwork. The ductwork has to be cleaned after the manufacturing so that the interior surface of the ducts does not contain oil residues or other harmful substances. The ductwork should be protected from dirt and rain during the storage at the factory and during transportation, as well as at the construction site and in the temporary storage at the installation site. Open ends of ductwork have to be capped during the breaks of installation. The ductwork has to be built so that it can be easily cleaned without damaging the equipment. The ductwork has to be cleaned before the operational test of the air handling systems.

The use of air conditioning equipment during the construction work. The final air conditioning equipment shall not be used for heating, ventilating or air conditioning of the building during the construction process. The operation of air conditioning equipment should be limited only to perform the balancing and measurements after the operational tests.

Air handling units. The supply air of the air handling units has to be cleaned with a filter with dust removal efficiency better than EU 7 (F7). The supply air must not bypass the filter media through the holes or openings between the frames and air handling unit.

Heat recovery from the exhaust air. The pressure of supply and exhaust air has to be controlled so that exhaust air cannot flow through possible leakages in the heat recovery unit to the supply air. Regenerative heat recovery equipment (heat wheel etc.) can be used only when the exhaust air does not contain tobacco smoke or other harmful contaminants.

Use of return air. Return air should not be used in air handling units with the exception of air handling units which only serve one dwelling.

The construction of air handling units. The interior surfaces of air handling units have to be easy to clean. The air handling units have to be air tight so that unclean air cannot enter to the supply air flow.

Cleaning of the ducts. Supply air ductwork has to be inspected with a maximum interval of five years. If the duct contains dust (dust accumulates when sweeping the surface), the ductwork has to be cleaned.

Replacement of filters. The filters of air handling units have to be replaced according to final pressure drop defined by the designer or, at latest, when 50 % of the area of the back side of the filter media has changed its color due to dust.

Structural and architectural work

The section dealing with construction work presents the requirements in the following areas: 1) Separation of the rooms with different categories; 2) Transportation of materials and accessories; 3) Storage of building materials on the construction site; 4) Protection of building materials during the installation and actual construction work; 5) Labeling and protection of cleaner areas during the construction; 6) Cleaning of the spaces during the construction; 7) The final cleaning of the spaces.

Classification of finishing materials (Part 3)

The purpose of the Classification of Finishing Materials is to present requirements for the materials used in common living and work spaces to achieve good indoor air quality. The goal is also to enhance the use and development of low-emitting materials. However, the use of low-emitting materials does not guarantee good room air quality. Ventilation has at the same time to be adequate and the materials should be used according to the manufacturers' specifications. For example, very few materials can stand for excessive moisture. Materials should also be easy to clean.

The Classification of Finishing Materials has three categories, category A being the best and category C containing materials with highest emission rates. Because total emission and concentration in room air depend on the amount of used materials, the Classification gives guidelines for the use of various materials. When the best indoor air category I is selected, the use of higher-emitting materials (categories B and C) has to be limited.

Requirements for finishing materials

Category A: Category A is designated for natural materials, such as stone and glass, which are known to be safe in respect of emissions, and for materials which fulfil1 the following requirements: 1) The emission of total volatile organic compounds (TVOC) is below 0.2 mg/m^2h; 2) The emission of formaldehyde is below 0.05 mg/m^2h; 3) The emission of ammonia is below 0.03 mg/m^2h; 4) The emission of the carcinogenic compounds (due to IARC) is below 0.005 mg/m^2h; 5) Material is not odorous (dissatisfaction with the odor is below 15%).

Category B: 1) The emission of total volatile organic compounds (TVOC) is below 0.4 mg/m^2h; 2) The emission of formaldehyde is below 0.125 mg/m^2h; 3) The emission of ammonia is below 0.06 mg/m^2h; 4) The emission of the carcinogenic compounds (due to

IARC) is below 0.005 mg/m²h; 5) Material is not strongly odorous (dissatisfaction with the odor is below 30%).

Category C: Category C is for the materials which do not have emission data or the emission data exceed the values specified for materials of category B.

Classified materials must have a product specification which should present emission data and the possible limitations for the use of material and the requirements for environmental conditions when the material is applied. The producer should also have an acceptable quality control system.

The emissions of the materials shall not be greater when the material is in actual use than in the measurement test conditions. For example, the materials which are intended to be used in wet conditions have to stand for high moisture concentration without damage or increase in emissions.

The use of finishing materials

The finishing materials should be selected mainly from category A for the indoor climate category I. The finishing materials belonging to category B must not cover more than 20% of the interior surfaces of a room or not more than 1 m^2 per floor area. The use of the materials belonging to category C should be limited to minimum.

The finishing materials used in indoor climate category II should belong mainly to categories A and B. Materials belonging to category C should not cover more than 20% of the interior surfaces of a room or not more than 1 m^2 per floor area.

Measurement methods

The measurement of emissions should be performed when the material is in the actual final form intended for its use. Material emissions shall be measured according to the methods specified in Nordtest or ECA guidelines /4, 5/. The sampling and analyses of chemicals have to be made according to commonly accepted methods. Emissions of materials shall be measured after four weeks from the date of the production or the date when the material is unwrapped from the air tight packing. The samples shall be stored for four weeks before the test in a climate chamber. The time of four weeks will be calculated for paints, levelling agents, adhesives, sealants, etc., from the date of application on the surface. The procedures used in the sample selection and preparation follow the principles outlined in the project "European Data Base on Indoor Air Pollution Sources" /3/.

Experience in practice

The Classification of Indoor Climate, Construction, and Finishing Materials has been adopted for several construction projects. Construction clients and designers have used it as a tool in setting target values for indoor climate and in achieving the goals during the construction. In a year, 2,000 copies of the Classification have been distributed to various parties involved in construction. The Classification has also been translated into English.

The classification has been used in several building projects.

The Classification has been received positively also by the construction industry and by the manufacturers of building materials.

The first part of the Classification, which deals with the target values of indoor climate, have been used widely by designers in various building projects. The target values have also been used as a reference values in the building investigations.

The second part dealing with construction cleanliness has maybe faced the strongest opposition from contractors, the main reason being the unawareness of the nature of the indoor climate problems. However, after the major designers having adopted the principles presented in the Classification in their design it looks like the document is gradually changing the construction practice. It is, for example, more and more common that designers specify that the ducts have to be washed after the manufacturing process and handled on the construction site with capped ends. The largest project in Finland where the classification of the construction cleanliness has been used is the NOKIA headquarters building where 25 km of cleaned ducts have been installed, and the classification followed in other aspects, too. The classification has also been used succesfully in the design and construction of an appartment building for people suffering respiratory diseases /6/.

The third part of the classification, which deals with the material emissions have been used in practice since June 1996. The driving force in the classification for material emissions has been the Finnish Building Information Institute, an organization owned by Finnish architects, which has founded a committee to classify the materials. It makes decisions on the categories of the finishing materials. In the committee, there are representatives of researchers, various construction parties, and material manufacturers. The Finnish Building Information Institute publishes data on classified products. Thus the material manufacturers get free advertisement through the Institute. The committee's decision on emission classes are based on the test data from the certified laboratories. By the end 1997 about one hundred and fifty materials have been granted with the class Ml label. The material manufacturers have started to use the classification certificate and label also in their advertisements, not only for professionals but also for public.

Guidelines for indoor climate investigations in residential buildings

J. Palonen, 0. Seppänen, K. Jokiranta
Laboratory of Heating, Ventilating and Air Conditioning, Helsinki University of Technology, Espoo, Finland
R. Ruotsalainen
Finnish Asthma and Allergy Assosiation, Helsinki, Finland

Abstract
Healthy and comfortable indoor climate is a basic requirement for all buildings. Complaints by the occupants and observed defects and malfunctions of the building and its mechanical equipment are reasons for investigating and renovating the building. The goal of the research was to develop a method for investigating indoor climate in residential buildings. Guidelines for the investigation were made for both houses and apartment buildings. As the outcome, the investigations produce data for the renovation of indoor climate in buildings. The indoor climate investigations in residential buildings proceed step by step, and the levels can be applied according to the buildings investigated. The guidelines consist of the measures and methods including measurement equipment needed in the investigations. The indoor climate investigations include the following steps:

- assessing of indoor climate problems by interviewing occupants and maintenance personel of the building
- examining of the performance, condition and balance of ventilation system and comparing them to the design specification
- examining of air flows, pressure differences and air tightness of the building
- examining of the performance, condition and balance of heating system
- examining of the condition of constructions, e.g. water damages and the effect of ventilation on them
- assessing of thermal conditions, humidity and pollutants
- measuring of indoor climate parameters (temperature, humidity, pollutants of indoor air, etc)

Keywords: indoor climate, dwellings, investigation method, diagnostics

Introduction

According to research results /1/, indoor climate in buildings varies a lot. For example, the difference of air flows can be tenfold between buildings. The defects of ventilation equipment, and moisture and mould damages are prevalent. The cost caused by poor indoor climate in the Finnish residential buildings has been estimated to be about four billion Finnish mark per year, being twice as much as the cost of energy consumption for ventilation. The consequences of poor indoor climate appear as various symptoms and illnesses, and discomfort.

Investigations /2/ concerning mechanical exhaust ventilation in block of flats built in the 1960's and the 1970' showed that when all the windows are closed, only one fifth of the exhaust air flows from kitchen or bathroom met the requirements of the National Building Code of Finland.

There are 2.4 million dwellings in Finland, one million in detached houses and one million in blocks of flats. The average age of the whole stock of dwellings is 31 years. The 300 000 dwellings in terraced houses are typically fairly new, more than 60 per cent of the terrace houses has been built after 1980. Mechanical exhaust is the most common ventilation systems in Finnish dwellings.

Table 1. Ventilation systems in Finnish dwellings.

Year of construction	**Block of flats**	**Detached houses**
before 1960	natural ventilation	natural ventilation
1960-1970	mechanical exhaust	natural ventilation
1970-1980	mechanical exhaust	mechanical exhaust
1980-1990	mechanical exhaust	mechanical exhaust mechanical supply and exhaust
1990-	mechanical exhaust mechanical supply and exhaust	mechanical supply and exhaust

Blocks of flats do have central heating system based on district heating. About 40 % of detached houses are heated using electricity and with oil heating 30 %.

The aim of the project was to develop a method for indoor climate investigations and to formulate guidelines for how to investigate indoor climate in residential buildings. The investigation of the building will produce basic information on indoor climate. The reasons to investigate indoor climate can be, for example, poor performance of the building or of the mechanical equipment, or symptoms and complaints by the occupants. The main goal is to prevent indoor air quality problems by increasing regular maintenance and inspection work in dwellings. The project was a part of Building Renovation Program (REMONTTI Programme) /3/ financed by the Finnish Ministry of the Environment.

Contents of guidelines

The guidelines present a method to investigate the problems of indoor climate in dwellings in phases. The guidelines include also lists of typical indoor climate problems and their causes, table 2. Measurements of parameters that are often difficult to interpret will be made only after preliminary walk-through. The starting point is to examine the performance of the mechanical equipment and the defects in them. The necessary and urgent repairs for the buildings, for example technical breakdowns and the need for basic balancing of ventilation and heating system, will be presented as a result of the indoor climate investigation. In the report, some measures to improve the indoor climate in buildings are presented.

The investigations proceed, deepen and expand in phases. Typical indoor climate investigations in dwellings as well as the methods of measurement and interpretations of the results are described. A previous condition assessment of the building can be the starting point for the indoor climate investigation. It is beneficial and also cost effective if other investigations can be performed simultaneously in the same building, especially the investigation of mould problems. Descriptions of typical malfunction and defects of ventilation systems with a recommendation for improvement are a part of the guidelines for the indoor climate investigation.

Structure of indoor climate investigation

The structure of the indoor climate investigations is presented in Figure 1.

Acquisition of basic information

In the first phase, the necessary background data of the building are collected. e.g. the construction and IIVAC-systems, the operating time and zones of the ventilation system. The data are used to design measurements. A survey of previous evaluation assessments and investigations as well as other reports, measures and renovation will be made. Furthermore, the design and service documents are acquired in advance.

Overview of the recognized problems in dwellings is the starting point of the investigation: the complaints by the occupants and symptoms associated with indoor climate, and the defects of the building and of its mechanical equipment. The aim is also to try to find out the extent and seriousness of the problems.

The basic data are gathered with the help of the manager and janitor of the building. For a residential building, these data can be collected already at the ordering stage of the investigation. The model of the order is included in the guidelines.

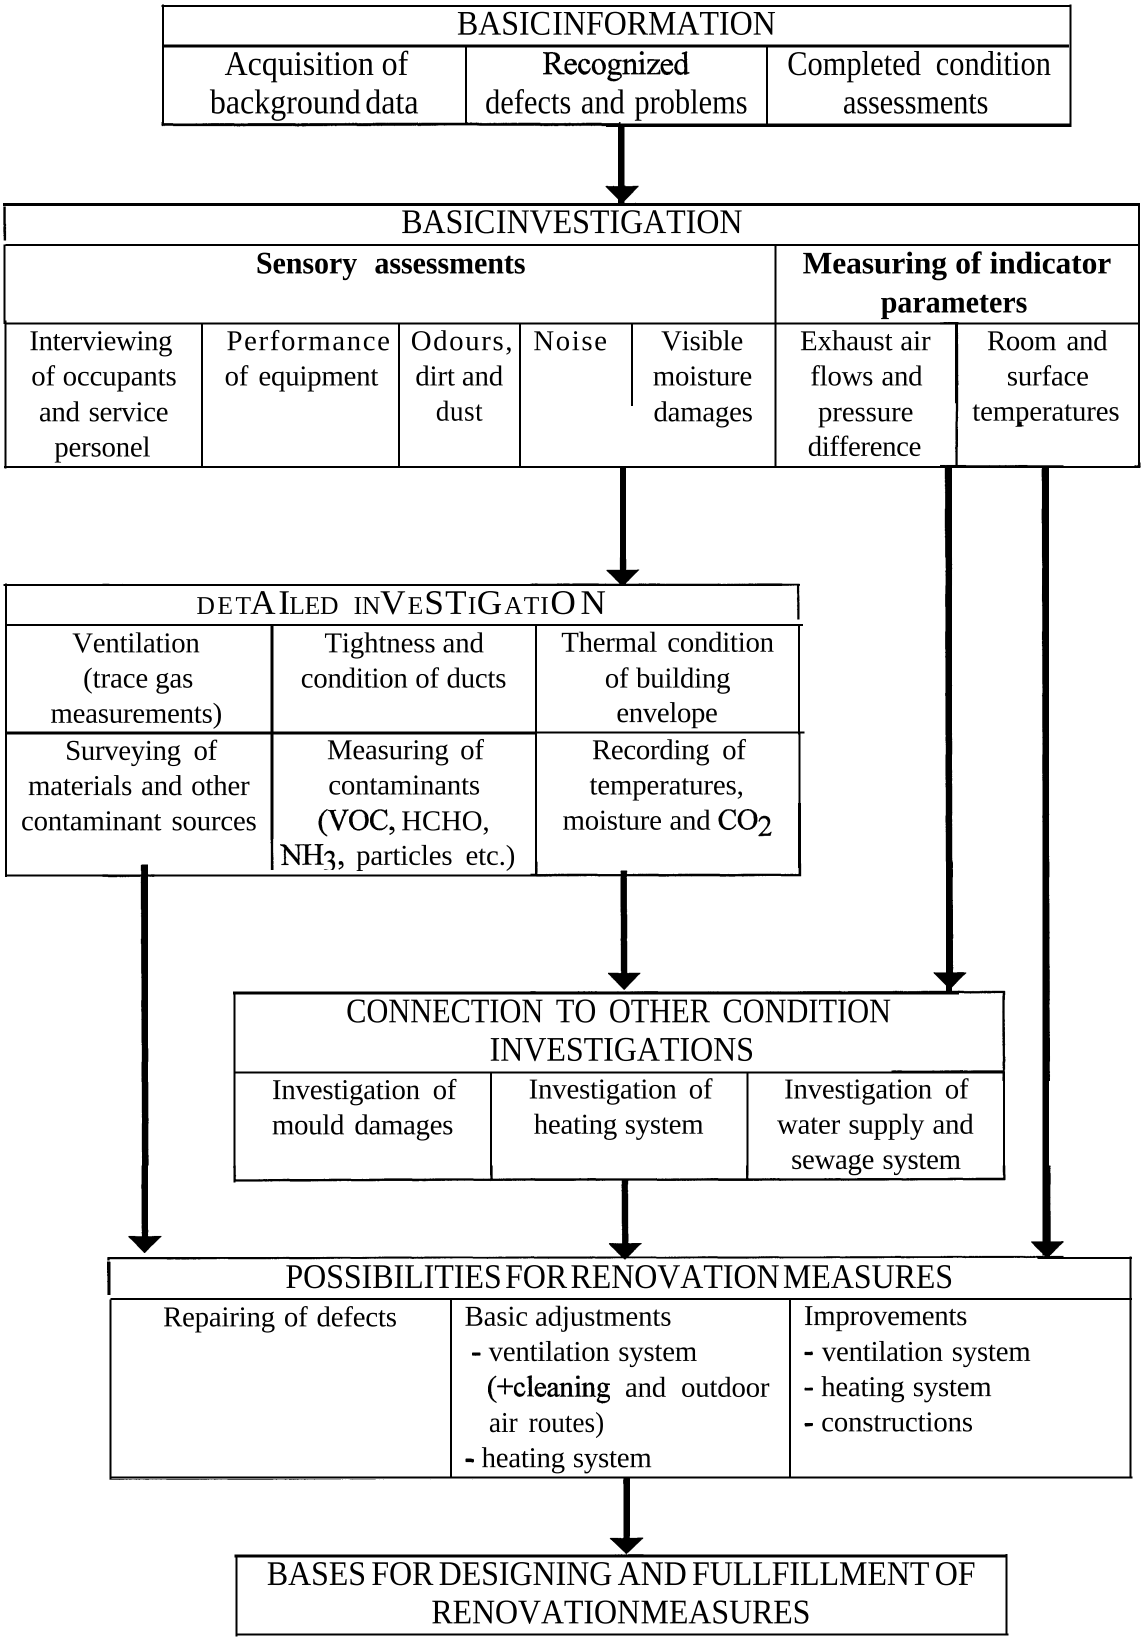

Figure 1. The structure of the indoor climate investigations.

Sensory assessment

When specifying the quality and extent of the problems, the key persons of the building are interviewed. Depending on the size and ownership of the building, the key person include the chair of the building board or a representative of the tenants, the manager of the building, and the janitor. At the same time, inadequate data are completed. The need for a questionnaire for the occupants is estimated. For example, in large building complexes with the questionnaire for the occupants, poor operation of ventilation and heating system can be limited to certain zones.

This phase is based on a walk-through survey. The building is examined from outside and by walking through the common spaces and the roof. The functioning and operating times of the ventilation equipment are checked in the machine rooms of air handling units and the main distribution board; operation of the fans and timers are checked at each speed. The set values, control curves and the functioning of timers of the heating system are checked in the heat distribution room.

All apartments in the building must be investigated. In the apartments, the indoor air quality is assessed on sensory basis. In the assessment, the stuffiness of the room air is evaluated and possible odours specified and their sources located. The condition and operation of the ventilation system in the dwellings are assessed. The cleanliness and the position of the supply air inlets, exhaust air outlets, and the kitchen range hood as well as transfer air routes are examined; special attention is paid to the flow routes of outdoor air. The condition and performance of heating equipment are examined (e.g the type of radiator valves). Visible moisture damages are recorded with the help of the check list of mould problem investigations. Based on the results, the need for special mould investigation is assessed.

Measuring of indicator parameters

Very seldom a single contaminant in the air is the reason for the problems. This is why there is usually no need to measure the concentration of single substances in the beginning of the investigation unless there is a good reason to suspect that some material emit that a specific chemical. On the other hand, measuring or assessing of some indoor climate parameters as an indicator is often very useful. The occurrence of a factor and order of its magnitude may describe the quality of the building or a special kind of problem.

Some apartments are selected by taking into account the zones of the ventilation and the heating system (in apartment buildings for example at different staircases both on the top and the first floor). The following factors are suitable to be taken as the base of first hand conclusions; exhaust air flows, pressure differences, air temperature, surface temperatures, carbon dioxide concentration, and the noise caused by ventilation and heating system. It is often plausible to do the evaluation of indicator parameters simultaneously with sensory assessments. Air flows in all dwellings having natural exhaust ventilation or their own ventilation unit must be measured. The condition, cleanliness and adjustment of ventilation equipment are worked out more precisely (fans, air intake, filters, heat recovery, ductwork).

Measured values are compared with values in the National Building Codes or in the Classification of Indoor Climate /4/. Air temperature is compared during the heating period to the value of 21,5 °C. The reason for an air temperature value deviating more than +/- 1,5 °C has to be found out. Exhaust air flows are compared to design or guideline values. When this deviation is more than +/- 20%, this part of ductwork needs to be adjusted. When the exhaust air flows are clearly lower than their target values, the need for outdoor air routes are assessed by measuring the exhaust air flows with the window open and closed. The sufficiency of the fan power is also assessed. With the trace smoke, outdoor air routes and internal air flows are studied, and draughty locations and air leakage in the building envelops are searched for. The pressure difference between room air and outdoor air and staircases are checked. The moisture loads of the apartment are evaluated (the use and type of humidifiers, the amount of laundry and the way of drying it, and the frequency of use of shower and sauna). Also the sources of contaminants are recorded (e.g. pets and amount of dust accumulating surfaces).

In the common spaces, the same indicator parameters as in the apartments are measured (sauna department, laundry rooms, drying rooms, club rooms, store rooms, garbage rooms, survival shelters, and possible commercial spaces).

Detailed investigations

The thermal insulation of the building envelop is assessed when it is suspected that the capacity of the radiators is inadequate. Measuring of air leakage in dwellings is needed when designing the basic improvement of ventilation system. The air tightness of the external envelope in buildings with natural or mechanical exhaust ventilation system has been a typical constructional deficiency impairing indoor air quality in dwellings. In a building with tight envelope, the air change rates are almost systematically lower than the target values. Measuring the operative temperature is necessary in old dwellings and in those with floor or ceiling heating. A long-term recording of room temperature may be needed for example when night setback is used. The CO, concentration in the buildings is measured if the CO, production before the measurement is representative. By the long-term recording of CO, concentration, the adequacy of air change in bedrooms can be evaluated.

In a building with natural ventilation, or with mechanical exhaust with , the air tightness of the ducts is measured when needed. With trace gas measurements, contaminant transfer between apartments can be investigated. Also, the actual air change rate in a dwelling can be measured exactly with trace gas techniques.

A survey of building materials is made when searching for a reason for an exceptional odour or high contaminant concentrations, for example dust, carbon monoxide, ammonia, formaldehyde and volatile organic compounds. The need for measuring radon is estimated on the basis of soil, type of foundation and ventilation system.

Possibilities for renovation measures

Reporting of indoor climate investigations includes the recommendations for essential and urgent measures for renovation, for example poor operation of the ventilation and heating system, and the need for basic adjustment and cleaning of them. In the report, also other alternatives for improving the indoor climate in apartments are described. They include 2-3 alternative ways of repair of different quality and cost. These include, for example, equipping the apartments with simple outdoor air inlets (low level), heating of outdoor air with supply air heater or supplying it through a radiator (medium level), or installing of mechanical supply and exhaust ventilation system in every dwelling (high level).

Reporting of the method

Indoor climate investigation produces the basic data for the renovation. The guidelines include also lists of typical malfunctions of ventilation and heating system and their causes. Furthermore, they include the measurements and equipment used in the investigations as well as possibilities for measures of renovation. There are also instructions to the client on how to order the indoor climate investigation.

Table 2. Typical indoor climate problems and their reasons.

Problem	Reason
Draught	too low room temperature - too low surface temperature - too high ventilation rate - high air supply velocity - too low supply air temperature - badly working or no fresh air inlets - air leakage - too narrow transfer air routes
Low room temperature	- unbalanced heat distribution system - wrong use - design failed - thermostatic valve do not work - clogged pipe - too high ventilation - insufficient or damaged heat insulation - leakage - too low supply air temperature
High room temperature temperature	- unbalanced heat distribution system - wrong use thermostatic valve do not work - solar radiation - warm spaces adjacent with dwelling (boiler room, laundry)
Unsteady room temperature	- untightly outer wall - unstable heat distribution system
Cold floor	- insufficient heat insulation - air leakage from joints between floor and wall - badly working fresh air inlets
Dry air	- low outdoor temperature too high ventilation rate - too high room temperature
Condensation on surfaces (also windows)	- insufficient ventilation - overpressure - insufficient heat insulation - furniture tightly in outer wall - humidifier - high humidity load in bathroom
Stuffiness	- insufficient ventilation high room temperature - high indoor humidity - too many habitant - odour emitting building material
Unpleasant odour	- sewer gases mould damage building materials
Odours from other dwellings and spaces	- leakage between dwellings, high pressure difference between dwellings - location of fresh air inlet
Noise	noise from ventilation system - noise from heating or water supply system poor sound insulation

CASE STUDY ON THE THERMAL COMFORT IN A SERIES OF STORES

G. Verbeeck, H. Hens
Laboratory of Building Physics, Department of Civil Engineering, Catholic University of Leuven, Belgium

Abstract
This case study contains an extensive thermal analysis of the indoor climate and comfort in the establishments of a store chain, with a comparison between the opinion of the personnel and the physical reality and with an extensive analysis of the causes of the comfort problems.

Every store is settled in an industrial building without capacitive walls and without a ventilation or cooling system. There were strong complaints about overheating during summer and about cold and draught during winter. The study was made by means of a survey of the employees and by extensive measurements during summer and winter (May 1993 until April 1994) of temperatures and air velocities in all the stores. For our analysis of comfort we used the Predicted Mean Vote (PMV) and Predicted Percentage of Dissatisfied (PPD) for the global thermal comfort and the Draught Rating (DR) for the percentage of dissatisfied due to draught. The values, calculated from the measurements confirmed the conclusions of the inquiry.

Simulation of the building showed that the strong overheating during summer was caused by the very high internal heat gains due to lighting. As the amount or type of lamps could not be changed, due to the marketing strategy of the store, the installation of a ventilation and cooling system appeared to be necessary. During winter, draught was caused by the bad construction of the entrance and exit locks for clients and trolleys. So reconstruction of these locks was necessary.

The applied strategy consisted of executing the necessary changes in one pilot establishment. These changes were evaluated in 1995 before applying them to the other establishments. To reduce the installation costs a combination of two ventilation/cooling systems was chosen: split units that cool the indoor air temperature and adaptation of already existing air groups that can mix indoor and outdoor air, so cooling can be minimised.

Also new entrance and exit locks were tested first in one establishment, to see if clients could manage them.
Keywords: comfort measurements, cooling, draught, overheating, store, survey, thermal comfort, ventilation.

1 Introduction

Since years the employees of the 6 establishments of an international store chain, complained about bad thermal comfort: globally too hot during summer and locally too cold and draught problems during winter. The internal heat gains are very high in all stores due to lighting, electrical equipment and the amount of clients. In none of the stores mechanical ventilation nor cooling was provided, except in the food section. There was only natural ventilation due to the air flows between the entrance and exit locks of the clients and the doors of the merchandise depots. The research is divided in a study of the summer situation and a study of the winter situation [1-3].

2 Description of the building

All stores have a similar structure: a ground floor with partly a high ceiling and partly a low ceiling, and a first floor with a smaller floor surface than the ground floor and a low floor-ceiling distance (3.10m). Fig. 1 gives a schematic plan of the buildings.

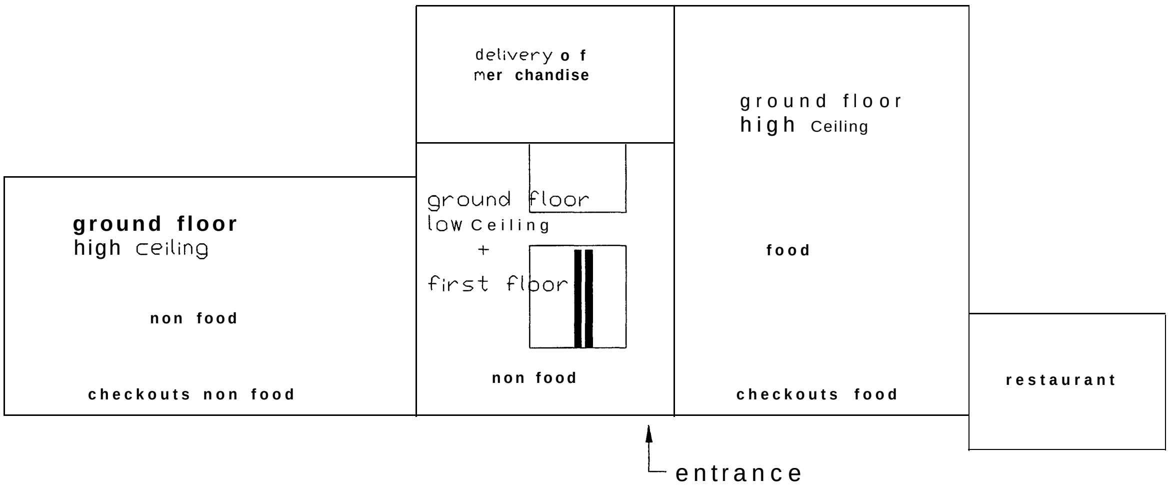

Fig. 1

3 Survey

In June 1993 a survey on thermal comfort was held in all stores of the company. Nearly 5 1% of the 3500 employees filled in a questionnaire. The specific comfort questions searched for the comfort judgement in summer and winter by means of two types of questions: questions on the general temperature impression during summer and winter and questions on local discomfort during winter at neck, back, legs, feet and head. For the judgement the psycho-physical voting scale of the ASHRAE comfort studies was used: +3 = hot, +2 = warm, +1 = slightly warm, 0 = neutral, - 1 = slightly cool, -2 = cool, -3 = cold.

The results of the survey formed the reference for the further analysis. They expressed a problematic comfort situation, both in summer and winter. The locations with strongest complaints differ for both seasons.

During summer there are general complaints of strong overheating, except in the food sections. In each store the differences between the sections are quite the same. Table 1 gives a summary of the results.

location	store 1	store2	store3	store4	store5	store6
1	2.44	1.93	2.88	3.00	2.94	3.00
2	1.14	2.45	2.08	2.39	2.59	2.24
3	-0.11	0.07	0.00	-0.24	0.18	-0.06

Table 1: mean values of the general temperature impression during summer (1=first floor; 2=non food ground floor; 3=food ground floor)

In winter the complaints are mainly about cold and draught. Table 2 gives a summary for all stores for the general temperature impression and for the draught impression.

location	store 1	store2	store3	store4	store5	store6
general temperature impression during winter						
1	-1.45	-1.03	-1.37	-1.23	-0.63	-1.21
2	-0.62	0.40	-0.18	0.05	0.05	0.00
3	0.28	-0.64	1.04	0.95	0.33	0.59
draught impression during winter						
1	-1.34	-1.35	-1.37	-1.29	-1.05	-1.05
2	-0.42	-0.07	-0.31	-0.12	-0.10	-0.32
3	0.40	-0.46	0.63	0.64	-0.28	0.47

4 Measurements and calculations

4.1 Measurements

Through measurements of the indoor climate, we looked for a confirmation of the survey and a specification of the causes of the thermal discomfort. The measuring campaign consists of two parts: continuous temperature measurements during a longer period and short-term measurements with a comfort apparatus at different places.

4.1.1 Continuous measurements

In summer, the continuous measurements are made in 2 establishments on the first floor ($420m^2$) during 7 to 8 weeks. It concerns measurements of surface temperatures on the floor, walls, false ceiling and roof, temperature gradients for two heights and air temperatures at 13 different places at the height of 1.80m (head level).

In winter, the continuous measurements are made in 2 establishments at the checkouts during 10 weeks. Air temperatures are measured at foot level, back level, neck level and head level.

4.1.2 Short-term measurements

In each store, short-term measurements are made with a comfort apparatus from Brüel & Kjaer: it is a portable tripod with 4 small measuring instruments, that register every 10 sec. the air temperature, the radiant temperature of two hemispheres, the relative humidity and the air velocity (mean value and standard deviation over 10 sec). In the summer period, we measured at 4 to 5 places, each time during a day or a week and the measurements are averaged per 10 minutes; in the winter period, measurements are made at 10 to 11 places, each time during a few hours and are averaged every minute to get a clear picture of the fluctuating character of the indoor climate.

4.2 Principles of the applied calculation method

4.2.1 Global thermal comfort

To judge global thermal comfort, we used the thermal comfort theory, developed by Fanger [4]. He deduced the thermal index ‘Predicted Mean Vote’ (PMV), which takes into account the air and radiant temperature, the relative humidity, the air velocity: mean value and turbulence, the activity level (metabolism) and the clo-value: measure of the thermal quality of the clothing. This thermal index is connected to the frequently used ASHRAE-scale (see above). By measuring the climatic parameters and assuming the activity level and the clo-value for a certain situation, the PMV can be calculated for that situation. Connected to the PMV-value, Fanger uses a more comprehensible index, the ‘Predicted Percentage of Dissatisfied’ (PPD). A situation is considered acceptable if it does not exceed a maximum of 10 % of dissatisfied persons (PMV = -0.5 to +0.5).

4.2.2 Draught

Fanger et all [5] also developed a model to quantify the draught risk by the thermal index ‘Draught Rating’ (DR). Determining parameters are the air temperature, the air velocity and the air turbulence, from which the air turbulence is the most important. Studies showed that a fluctuating air velocity, although with a low mean value, is experienced as much more uncomfortable than a constant, higher air velocity due to the constantly fluctuating cooling of the body [5-8]. Therefore it is possible that, based on the mean air velocity, thermal comfort seems to be acceptable, but that, due to too high fluctuations, the percentage of dissatisfied because of draught, is unacceptably high.

4.3 Building simulations

With the building simulation program CAPSOL [10], we simulated the thermal indoor climate during summer for the non food sections of the different stores. Outdoor climate is the month of July from the TRY-year for Ukkel (near Brussels). Aim was to analyse the influence of the internal heat gains due to lighting, electrical equipment and clients versus the influence of solar gains on the overheating.

Table 3 gives per store the internal heat gains due to lighting and electrical equipment with the distribution for the different zones and the mean daily amount of clients. Each client represents on average 120 Watt. For the simulations the mean daily amount of clients is transformed into an hourly amount by a weight factor.

establishment	ground floor high ceiling [kW]	ground floor low ceiling [kW]	first floor [kW]	clients [amount/day]
1		68.1	108.9	5100
2		95.2	61.4	5050
3	100.2	54.6	83.1	5600
4	55.7	43.3	91.6	3300
5	115.5	96.9	53.7	5600
6	92.1	62.1	81.4	2400

Table **3:** internal heat gains with distribution over the different zones and daily amount of clients per establishment

We first simulated each building without internal heat gains. Although there are differences between the stores, a global tendency can be observed: when there are no internal heat gains (IHG), there is a very strong fall of the indoor temperature: at the ground floor the temperature never > 24°C; at the first floor the temperature without IHG almost never > 26°C, whereas with IHG the temperature often > 30°C.

To analyse the influence of solar gains, we compared the stores with very few windows in the shopping zone, with the stores with much more windows. Comparing them for IHG = 0 does not show a considerable difference. This demonstrates the minor role of solar gains on the indoor climate.

The winter situation is not simulated. The constantly changing interaction between indoor and outdoor climate through the entrance and exit locks creates a very complex situation that hardly can be simulated in a correct way.

5 Discussion

5.1 Comparing survey - measurements

Comparing the results of the measurements with the survey, we notice that for the summer situation similar trends are found in both calculations and survey. Nevertheless for some sections, there was a discrepancy between the survey and the calculations. This is probably due to the lack of thermal comfort of many years that the employees wanted to emphasise by giving a higher (more negative) vote than can be observed in reality. Another reason can be the radiant temperature of the ceiling. It may be assumed that this temperature is much higher than the floor temperature due to the great amount of lamps. By calculation we found for the ceiling a mean temperature of 29,4°C, whereas we measured a mean radiant temperature (average of floor and ceiling) of 26°C. The effect of this higher ceiling temperature is not included in the calculated PMV values, but will affect the thermal comfort negatively, especially with the low floor-ceiling distance.

For the winter situation there is a greater difference between the results of the survey and those of the measurements. For locations with higher temperatures, both in the survey and the measurements the distinction is made between the thermal situation ("neutral") and the draught situation (mostly unacceptable: > 10 to 15%). For locations with lower temperatures, the agreement between survey and measurements is less: the measurements show an acceptable thermal situation and an unacceptable draught situation, whereas the employees consider both the thermal and the draught situation as unacceptable. It is notably that for 60% of these locations, the percentage of dissatisfied due to temperature from the survey, agrees very well with the calculated draught rating. This confirms the assumption that people not always distinguish between the sensation of high fluctuating air velocities and the sensation of low temperatures, because of their similarity (a local cold feeling).

The analysis shows that during winter, there is a draught problem and not so much a temperature problem, especially near the entrance and exit locks of clients and merchandise. So solutions have to be searched in stopping these turbulent draught flows.

5.2 **Solutions**

5.2.1 Proposals

For the summer situation, all results show that the high internal heat gains cause the strong heating up of the building. But because of the very strict requirements for colour reproduction and light intensity, asked by the company, only extraction of the ventilation air through the lamps, to remove the convective part of the heat emission by the lamp, was a possibility to reduce the cooling load.

So the preferential solution is forced and controlled ventilation with fresh air. We analysed the possibilities of night-ventilation, of day- and night-ventilation and the effect of the magnitude of the ventilation rate. To avoid complaints of draught the ventilation rate has to be restricted during working hours, whereas for night ventilation, simulation shows that the efficiency increases very slowly once the ventilation rate exceeds 3.5/hour. Furthermore a higher rate includes higher energy use. So for further calculations we only considered the following ventilation rates: day-ventilation = 2. S/hour; night-ventilation = 3. S/hour.

Night-ventilation already improves the thermal comfort, but not sufficiently. Due to the high internal heat gains and the lack of heat capacity in the building, the building heats up quickly during the day. Day-ventilation contributes much more efficiently to the decrease of the indoor temperature. The simulation showed a remarkable improvement of the thermal comfort by a combination of day- and night-ventilation. **Only** on the first floor, even with day- and night-ventilation, we still get temperatures above 28°C. So additional cooling has to be considered.

During winter the problems are caused by too strong draught flows near the entrance and exit locks. The proposed solution consists of rebuilding the locks to break the draught current towards the checkouts.

5.2.2 Evaluation

Both for the summer and the winter situation, a store was chosen as pilot-project to realise the proposed solutions and to evaluate them, before the application in all other stores.

Considering our results, an independent consultancy office worked out a configuration with two types of ventilation systems. On the first floor the space is divided in different zones, each with one or more split- or air-groups with one suction opening and several blow-in openings. The split-groups, that suck in indoor air, cool it and blow it back into the room, are cheaper to install, but use more energy than the air-groups, that mix fresh air with indoor air to minimise the cooling load. For the air-groups they used existing groups that were passed into disuse. By using outside air, the energy use will be reduced, but the installation and maintenance costs are higher than for the split-groups.

With continuous and short-time measurements we analysed the improvement of the thermal comfort and compared the homogeneity of the temperature field of both ventilation systems. Continuous measurements are done on the first floor in one zone with a split-group and one zone with an air-group. We measured the air temperature under a blow-in opening, between two blow-in openings and on a location as far as possible from a blow-in opening. At the same time we measured on 23 locations with the comfort apparatus.

These measurements showed that the ventilation system realises a decrease of the PMV and PPD. Table 4 gives a summary for the first floor.

	present situation	original situation	difference
PMV [-]	1.14 - 1.47	1.63 - 1.83	0.36 - 0.48
PPD [%]	33.7 - 49.7	57.3 - 67.5	17.8 - 23.6
DR [%]	7.2	4.5	-2.7

Table 4: Comparison between original and improved comfort situation

Both systems are adjusted for a blow-in temperature of 21°C. The mean air temperature decreases from 27°C to 22.3°C. The radiant temperature decreases from 27°C to 23.3°C. As table 4 shows, the PMV decreased with 0.42. So comfort improvement has been realised, but it is still not optimal due to the rather high radiant temperature and the rather high activity level of the employees.

Analysing the homogeneity of the zones, we find that both ventilation systems create a very homogenous temperature field. Also from a comfort point of view, we find very little difference between both ventilation systems. Table 5 gives a summary of the air temperature, the PMV, PPD and DR averaged for the zones with split-groups and the zones with air-groups.

metabol =2 1 OW	air-group		split-group	
clo-value = 0.8	on top	on floor	on top	on floor
temp [°C]	23.0	22.3	22.1	22.0
PMV [-]	1.39	1.33	1.32	1.29
PPD [%]	44.2	41.9	41.8	40.6
DR [%]	10.0	10.5	10.3	11.0

Table 5: averaged comfort values for the air-groups and the split-groups

To solve the draught problems during winter they installed in one establishment new entrance and exit locks, so that there is never a direct connection between the indoor and outdoor climate. They did not ask us to do new measurements, which probably means that there were no complaints anymore.

6 Conclusions

A very extensive comfort research was done by means of a survey, measurements and building simulations. The survey formed the most important part of the research. The measurements however confirmed the results of the survey: strong overheating during summer and local draught problems during winter. The measurements and building simulations were necessary to deduce the causes of the thermal discomfort. It showed us the importance of the internal heat gains for the overheating during summer, the influence of the ceiling radiant temperature and the need for a ventilation system. It also proved the difficulty for people to distinguish between temperature problems and draught problems.

The proposed solutions were evaluated after installation in one store. They realised an improvement of the thermal comfort, but did not give complete satisfaction for some problems. It is up to the company now to apply the improvements in the other stores and to evaluate the judgement of the employees on the new situation.

Environmental and energetic advantages of solar-collector

L. Kajtár, I. Erdõsi, Zs. Bakó-Biró
Technical University of Budapest, Hungary

Abstract

The solar-collector can be integrated into the roof-structure or subsequently onto flat or inclined roofs. Their aesthetic forms are fitting well to any building. The solar-collector analysed by us (product of the company Fiorentini Hungary) is designed to be integrated into roof-top place. The connecting pipes are hidden, remaining behind the collector.

The solar-collector can operate with air and water heat transfer fluid, separately or in common operating mode. Thus, the thermal energy of solar radiation can be used for domestic hot water applications and for different technological purposes as well (like grain drying).

Generally, the lavatories and baths are ventilated by fan in negative pressure. Using wintertime the solar-collector in air-based operation, heated auxiliary air is introduced into the house. During the collector's thermal examination in air, water and common operating mode, we could perform measurements and determine, on the base of the results, the capacity and efficiency in every case.

The application of solar-collector has multiple advantages: using solar energy we can save other resources, but in the same time the contaminant emission of unburned combustibles is reduced, producing therefore less pollution.

Generally, in case of solar-collector application, only the refunding of investments are taken into account, leaving without attention the environmental advantages, which have no direct influence to the expenses.

Keywords: efficiency, energy saving, solar-collector

1 Introduction

The utilisation of solar energy is influenced not only by geographical place, orientation and settle place, but the efficiency and operating parameters are important factors as well. The determination of efficiency and performance were the primary purposes during of our measurements. We were testing the influence of heat transfer fluid flow rate variation onto the efficiency and thermal performances of solar-collector.

2 Methods

The collector had westward orientation with a tilt angle of 45° during of our measurements. This angle is corresponding to a typical roof inclination. The useful surface of the solar-collector is A=1,6 m^2. The measurements were performed when the heat transfer fluid was: air, water, air and water.

During the examination, we were measuring the following parameters:

- atmospheric air temperature
- air velocity
- intensity of solar irradiation onto a horizontal surface (I, W/m^2)
- entry water temperature(t_{we}, °C)
- outlet water temperature(t_{wo}, °C)
- entry air temperature(t_{ae}, °C)
- outlet air temperature(t_{ao}, °C)
- air volume-flow ($\dot{V}_a$, m^3/h)
- water volume-flow ($\dot{V}_w$, lit/h)

The air and water temperature was measured by a resistance thermometer with 8 channels. The intensity of solar irradiation perpendicular to the collector surface was determined by calculations ($\dot{q}_{tot}$, W/m^2), using the results of measurements.

The collector was examined in cross-flow operating. In water-based operation mode, city water was introduced into the collector. The volume-flow was measured by water-meter and volume-meter, the air-flow rate by measuring orifice. The connection scheme of the measurement is represented on Figure **1.**

3. **Results**

Because of Earth rotation, during the measurements, the solar-irradiance intensity was varying **continuously.** Partially this is true for the atmospheric air temperature as well. During the evaluations, we were considering the „quasi-stationary" states and values around the maximum solar-irradiance ($\dot{q}_{tot}$) at the known orientation.

The efficiency of collector, corresponding to our results, is:

$$\eta = \frac{\dot{Q}}{A \cdot \dot{q}_{tot}}$$

Where: $\dot{Q}$ [W] - the transferred heat flow rate to the air and water heat transfer fluids.

The maximum efficiency and capacity of the solar-collector in different operating modes, based on the results, are the followings:

1. Water based operation mode:
   – capacity: 1070-1190 W
   – efficiency : 62-74%
2. Air based operation mode:
   – capacity: 260420 W
   – efficiency : 30-47%
3. Water and air, common operation mode:
   – capacity: 300-910 W
   – efficiency : 38-56%

We were determining the collector performance and efficiency at various water and air heat transfer fluid flow-rates. The influence of water flow variation onto the performance and efficiency of the solar-collector is represented on fig 2. The fig. 3. represents the influence of air heat transfer fluid.

4. **Conclusion**

The use of solar-collector is favourable in both, air and water operating modes. In the commercial distribution, these solar-collectors are classified with good performances. In the range of examined volume-flow the water was heated from 20°C to 34°C, in case of air the temperature increased from 28°C to 57°C which is suitable for technological purposes (like grain drying).

The opportunity of indoor environment performances improvement - component of the sustainable development

I. Bliuc, A. Radu and I. Baran
Faculty of Construction and Architecture, "Gh.Asachi" Technical University, Iaşi, Romania

Abstract
The requirements and performance criteria concerning the indoor environment are in a permanent development due to the increase of : users needs, outdoor environment degradation and constructive systems development.

From the sustainable development viewpoint, the quality level of a building includes the capacity to be permanently adapted to the new requirements through rehabilitation measures.

The paper is based on a study results on the indoor climate and energy consumption of a hostel building at which thermal rehabilitation works were carried out without any intervention on the natural ventilation system.
Keywords : Requirements performances, sustainable development, thermal rehabilitation

1 Introduction

The modern rehabilitation of buildings in Central and Eastern European countries is a stringent issue that presents an actual interest.

As in the Eastern side of Germany many buildings should be subjected to a large improvement operations concerning :

- energy conservation ;
- environment protection ;
- meeting all requirements concerning the sustainable development.

This operation will last for a few decades and will need large investments. This is why it is very important that the adopted solutions be well designed.

Now we realise that for a sustainable development, buildings should be designed for being periodically adapted to the requirements which result from the social, economical and technical progress [1].

The alternative should be that the buildings utilisation time to be reduced as in the case of all the other industrial products. After demolition, many materials would be used as raw materials transformed and reused.

It seems that the present and future economical situation doesn't allow this, and buildings must be used as long as their structure still satisfies the safety requirement.

At least once they can be strengthened.

In Romania, this last aspect is very important due to the periodicity of intense earthquakes (20...30 years). An additional element of difficulty comes out compared to the eastern side of Germany. For the moment, there is a tendency to pay attention especially to the safety problem against mechanical action and recently the thermal rehabilitation for energy conservation diminution of CO, emissions begins to be considered.

It that really enough ?

This problem is being discussed in the paper.

The opportunity was the restoration of a students hostel building. It has 5 levels and was built 30 years ago using reinforced concrete prefabricated panels.

Two intense earthquakes, the periodical variations of temperature and humidity, the corrosion and the infiltration at joints required the restoration.

2 General presentation of the building before and after the restoration

The analysed building is a students' hostel with the capacity of 300 places, made of reinforced concrete prefabricate panels, Figure 1.

The external walls have a sandwich structure, with thermal insulation core, made of cellular light concrete and a high percentage of thermal bridges. The external walls as well as the flat roof have ensured an insufficient degree of thermal insulation.

The heating achieved through the connection to the district heating system didn't allow the control and the monitoring of power consumption.

The thermal rehabilitation had in view:

- the additional thermal rehabilitation of the external walls and flat roof ;

• the increase of thermal protection degree of windows through the setting of an additional glazing in 50% of the number of the windows ;
• the use on the longitudinal façades of bow-windows which cover the rest of 50% of windows that play the role of solar energy collectors in a passive system and also the limitation of wind effects ;
• thermal insulation of the basement with expanded polystyrene protected by a concrete layer;
• the optimization of heating equipment working.

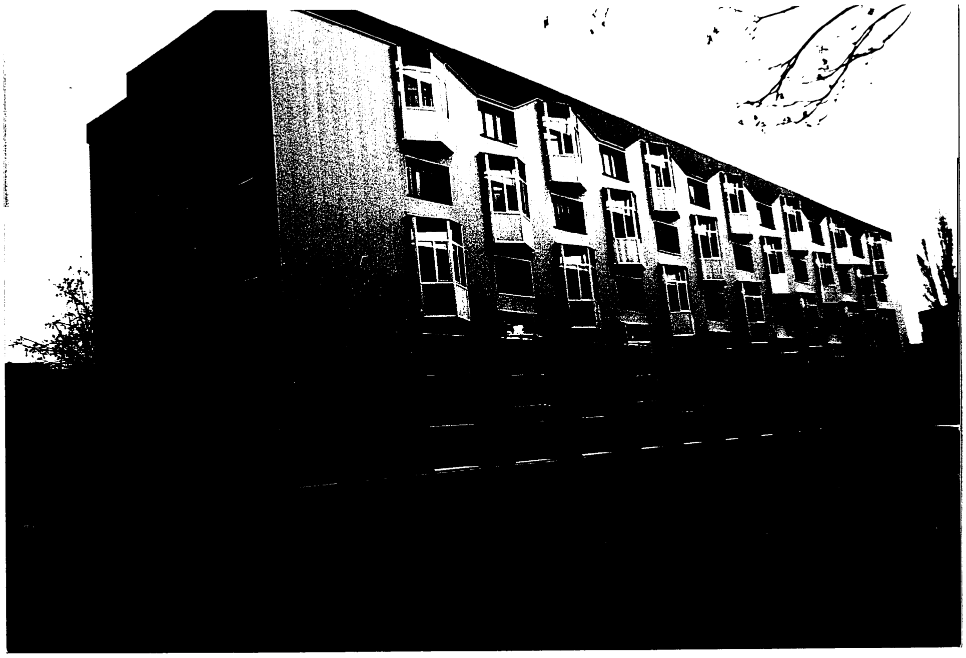

Fig. 1 General view of the students' hostel after the restoration

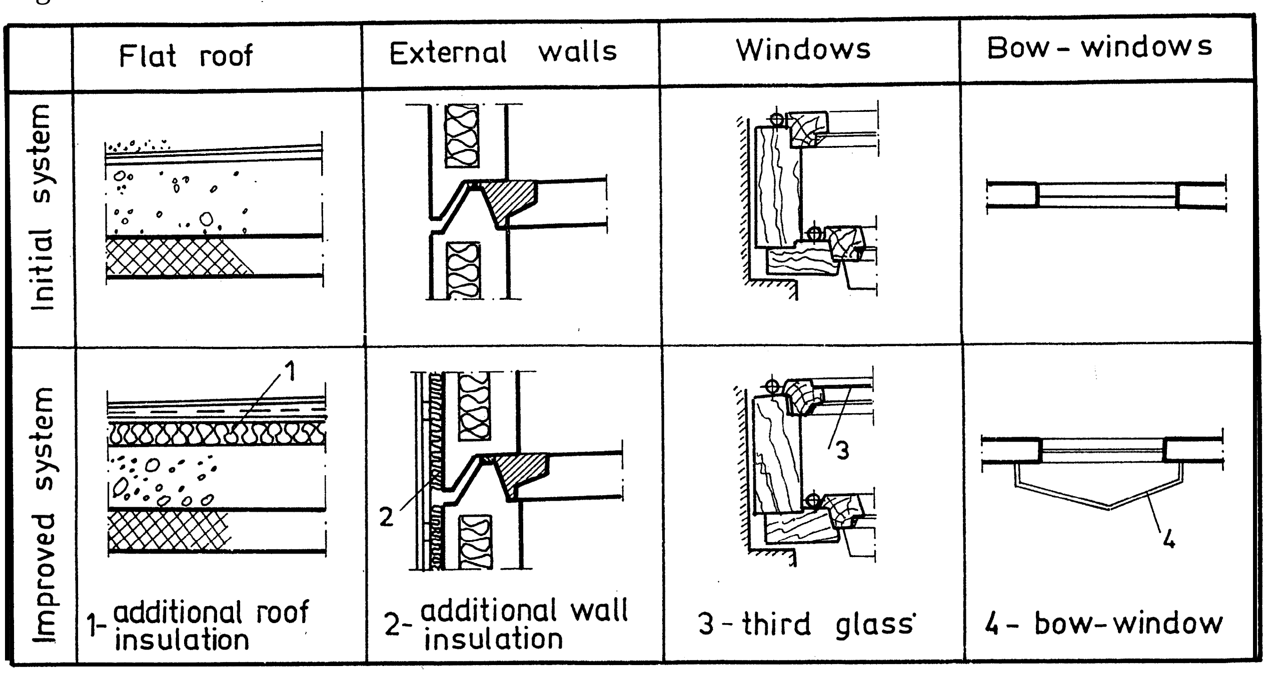

Fig.2 Constructive solution for envelope elements

The constructive solutions for the envelope elements before and after the rehabilitation are schematically presented in Figure 2 [2]. An optimal air composition is ensured through unorganized natural ventilation.

3 Effects of thermal rehabilitation on power consumption and indoor environment

As a result of thermal rehabilitation works, a decrease of power consumption for heating is estimated about 60%, this is reflected in the diminution of the value of specific power consumption index from 351,92 kwh/m² year to 127,55 kwh/m² year.

Measurements of indoor environment parameters were made simultaneously in the thermal rehabilitated hostel before being exploited and also, in two other similar hostels with no interventions for improvement, these measurements made during the winter of 1997 emphasised the following aspects :

- the air temperature in the thermal rehabilitated hostel had values with 3...9° C higher than those in the other uninsulated buildings ;
- the air temperature in the thermal rehabilitated hostel had close values, in all rooms, no matter of orientation in plane or vertical position ;
- the temperature on the inside surface of external walls is cvasiuniform, which shows that the unfavourable effects of thermal bridges were eliminated ;
- the relative air humidity in the rehabilitated hostel is clearly inferior compared to that in the other hostels. This is explained by the vapours emissions caused by the exploitation process.

The positive effects of rehabilitation works were obvious also in the results of determinations made in the periods, without heating system operating, there were recorded constantly temperature values for indoor air of about 20...21° C, when the mean outdoor temperature had values of about 4... 12° C.

4 Particularities of the exploitation regime and natural ventilation

The degree of occupancy of one room, with a 42 m² volume, is of 3 students. This number is in accordance with sanitary regulations.

The average period of occupancy is estimated, based on surveys, to 50 person · hours/day.

The necessary fresh-air flow rate for dormitories, recommended by regulations of different countries, varies between 11 and 30 m^3/h for every person [3]. This implies that for our case, the ventilation rate will vary between 0,78 and 2,14 h^{-1}.

Considering the adopted ventilated system, the refreshment of the indoor air will be made through air infiltrations caused by the leaks in carpentry and periodic opening of the window. In the cold period of the year, during the night, the ventilation will be made exclusively by air infiltration through carpentry leaks, under the influence of thermal air draft and especially of the mind pressure. In that case the estimated values of air flow rate and ventilation rate are presented in the tables 1 and 2.

It is observed that air mobility is due exclusively to wind pressure, the ventilation being totally insufficient at the wind speed below 4 m/s for rooms without bow-window and under 15 m/s for rooms with bow-window.

Temperature difference (T_i-T_e) [°C]	Thermal pressure difference Δp [Pa]	Before the renovation		After the renovation (in rooms with bow-window)	
		air draft [m³/h]	ventilation rate [h⁻¹]	air draft [m³/h]	ventilation rate [h⁻¹]
10	3,00	7,37	0,175	2,09	0,069
15	4,48	9,64	0,230	3,84	1,530
20	5,98	11,70	0,280	4,66	1,860
25	7,48	13,59	0,320	2,98	1,190
30	8,97	15,35	0,370	3,57	1,420
35	10,46	17,05	0,400	4,17	1,660

The redesigning of the ventilation system will take account of setting of admission holes on the façade and of discharge openings are equipped in the stair cage. These openings are equipped with ventilators (Figure 3), that are designed to ensure the minimum ventilation degree even in the most disadvantageous exterior conditions [4].

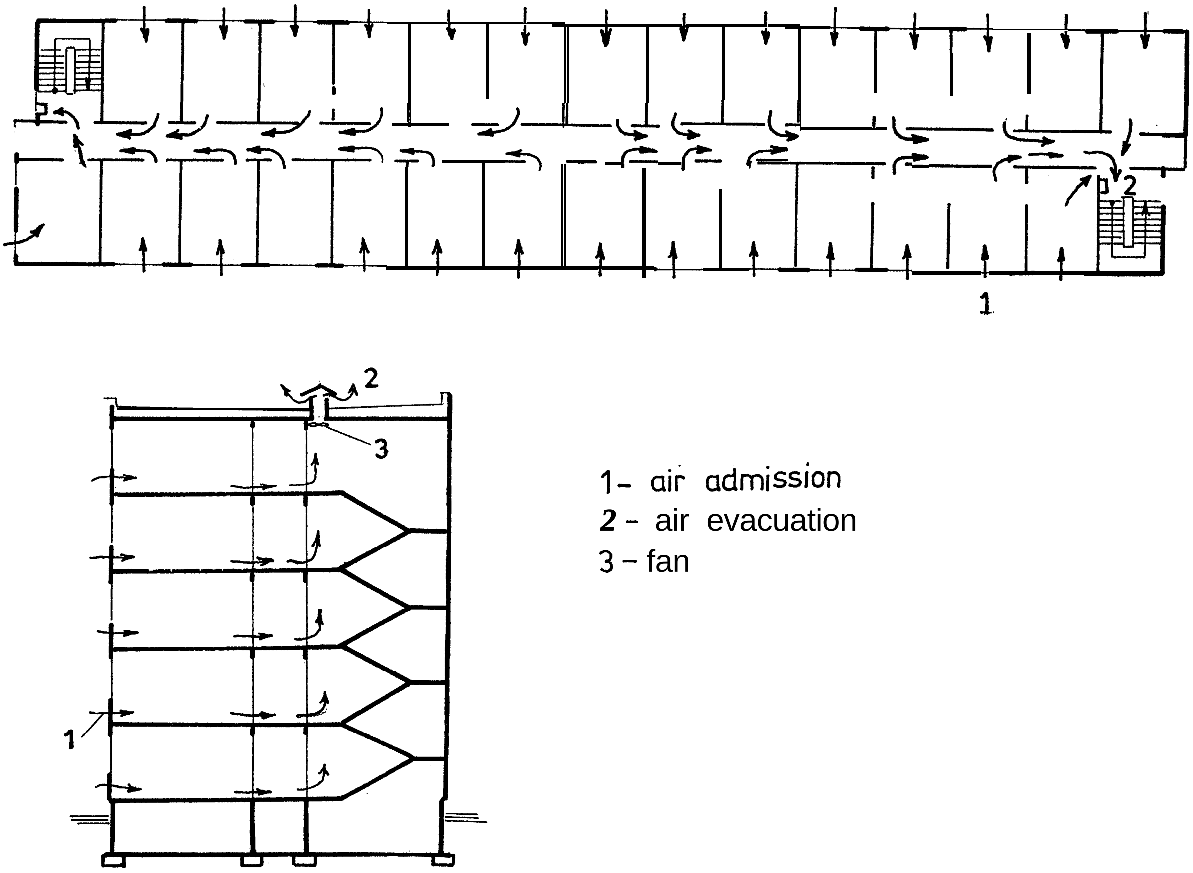

Figure 3 Suggestion for the ventilation system

5 Conclusions

On the list of qualities that have to be fulfilled by a building, the capacity of performance improvement occupies a top rarik, if we consider the criterion of sustainable development.

From the analysis of a real case of thermal rehabilitation of a building, there results the degree of accomplishment of this condition by the existent buildings.

The concept of rehabilitation must consider all the aspects related to the exploitation particularities and the quality of indoor environment.

The Human Olfactory System
Implications on Hormones Concerning Perception of VOC

E. Lövgren
Div. of Building Technology, KTH-Royal Institute of Technology

Abstract

Chemical substances like volatile organic compounds (VOC) in the indoor environment have been accused to be responsible for sick building syndrome (SBS), loss of tolerance and asthma among other annoying effects. But there are few explanations of the process in which low VOC concentrations can cause severe disturbances in the human body.

Humans can detect very low VOC concentrations through the olfactory system in the nose and sometimes percept this as a limited smell, but the effect on the body can be more influential in a longer perspective.

This paper tries to assess some of the existing knowledge of the specific process pattern that starts in building physics (emissions) and goes through structure biochemistry (VOC molecules), neurology (of the nose) and ends in endocrinology (hormone effects), immunology (tolerance) and probable human illness.

The approach is to follow a specific VOC molecule through a sequential theoretical study of the interaction between building and man. A possible way to describe the interaction and the effects of signal interference of chemical compounds like VOC on humans, can be summarized by the following hypothesis on how VOC would be perceptible but also misinterpreted by the olfactory system and the brain.

1. Chemical reactions with VOC can produce numerous unwanted chemicals indoors.
2. VOC molecules are chemical signals in the indoor air approaching the body.
3. VOC blends are signal patterns that involves information and the olfactory system collects this information about the situation outside the body and distribute it as molecular image patterns to different centres in the body.
4. Hormone reactions to these signals can make us sick. The outcome depends on how the brain interpret the signals from some of these molecules because they have points of similarity with other compounds in nature.

This paper can hopefully be of use as a interdisciplinary bridge, in the further detailed investigations of SBS and also give some clues to the connections between VOC, dampness, smell and illness to scientists working with healthy houses, ventilation and materials technology.

sick building syndrome SBS, humidity, smell, signal molecule images

1. Introduction

The olfactory system is a sensory system in the body specialized in detection, discrimination and identification of odorous compounds (1). Sensors are situated in the nose and can be compared to antennas receiving chemical signals from the environment. The olfactory system is probably the principle perception system for VOC.

VOC and odorous compounds would influence our everyday life, due to the reactions that our body would implement and the kind of messages it perceives, as results of interaction between the sensors and these chemicals. In this paper VOC molecules would be seen as signal molecules approaching the body from the outside (1, 2).

Two groups of signalling molecules inside the body that has great influence on our health are hormones (3) and cytokines (4). Some investigations state that VOC can mimic hormones (5). Building physicists with the knowledge about forces of change inside the building envelope (on molecules from VOC), structure biochemists with their knowledge of molecule surfaces (on molecules from VOC), neurologists with their knowledge about the transfer of electro chemical information (on molecules from VOC) through the neuron pathways, endocrinologists with the knowledge of hormone reactions in the body (on molecules from VOC), might need a common “language of VOC” to work out the final answer. Such a VOC signal language is proposed here.

This paper tries to focus on some of the scientifically accepted grounds that could be of help for further investigations. There is also an ambition to stimulate abstract thinking in new “pictures” that hopefully would give us more of a creative space and invite new scientists to this interdisciplinary field.

2. Chemical gas reactions in the indoor air and VOC

The perception of VOC is in principle an electro chemical reaction pattern which starts with a specific VOC molecule or a blend of different VOC molecules floating around in the indoor air. These molecules can be original emissions or reaction products from chemical gas reactions in the indoor air. VOC related gas ***reactions will be stimulated by*** at least three important factors, lots of raw material, favourable air conditions and energy.

¤***VOC emissions (raw material)*** could come from intake of ventilation air but outdoor air for ventilation has improved since the implementation of environmental regulations. In USA, investigations shows that out of hundreds of air pollutants covered under the existing US laws, only ozone and sulfurdioxid is more prevalent outdoors than indoors (6). All of these air pollutants are not VOCs and there is also VOCs that is not covered by US law. Measurements in the indoor air has identified more than 900 VOC (7). So where does all this VOC molecules come from ?

Raw materials in the shape of VOCs are essential for gas reactions and there are more than 45.000 building products for sale in Sweden today with a lot of known and unknown VOC and other compounds included (8), that could support reactions. Other VOC sources are furnishing and equipment that might be needed to use the building as a home or place of work. The procedure of maintenance with cleaning agents, wax and other different chemicals is also a source. Tobacco smoke is still another source of about 4000 chemical compounds and some of these are VOC (6).

An uncontrollable source of chemical compounds would be everything that we on a daily

To be able to analyse and understand how different chemical compounds, natural molecules as well as emission molecules and molecules produced by chemical reactions in the indoor environment, interact with humans, we have to take a closer look at the input systems where the interaction starts. The olfactory system (nose), the omalfactory system (eye), the respiratory system (lungs), the digestive system (stomach) and the skin system can be involved in these interactions.As the nose probably is the principle perception organ for VOC molecules and other molecules in the air we will concentrate this paper on the olfactory system, but that does not mean that the other input systems is negligible .

3. A brief description of the human olfactory system

To begin to understand the concept of smell, we have to consider the neurology of the nose and its physiological organ ***the olfactory system.*** The primary function of the olfactory system (olfaction is smell) is to signal to *the brain* via *the nervous system,* a change in its chemical environment (for example the presence of VOC molecules in the indoor air). This function can be important for escape reflexes, internal physiological regulation of the body and stimulation of different social behaviour (15, 20).

The principal parts of the olfactory system and its pathways for signals to important centres in the brain can be described as we follow a signal molecule.

The part of the olfactory system that interacts with the air molecules in the surrounding environment is called *the olfactory mucousa.* Its a layer 5 cm2 in the upper part of the nose cavity, where *odourant molecules* in the air meet with *odourant binding protein molecules.* (16). This area is used for detection of molecules in the air.

There is another layer 1 cm2 at the floor of the nose cavity, called *the vomeronasal organ* where molecules in liquid phase meet their binding molecules. Its not completely proven what this area is used for in humans, but a hypothesis is that its primary function is for detection of sexual pheromones. This is what most animal uses it for (14) so the hypothesis is not so improbable. There is evidence of human pheromones (17).

If the active surfaces *domain* on the odourant molecule and the domain of one of the odourant binding protein molecules would fit when they meet, the two molecules bind together. The odourent molecule would be transported by the binding molecule *(the odourant binding protein)* to a special target surface, *the olfactory receptor protein* (16). This receptor is placed on a *cilia* that is a part of an *olfactory receptor neuron cell (ORC)* (16). The number of ORCs is unknown for humans. Rabbits may have 100 millions (20).

When the effective domain area on odourant molecule is properly connected to the target surface on the cilia, the receptor ***transmits*** a chemical signal downstream the ORC (1) to the *olfactory knob* , where chemical signals from many cilias would be mixed to an electric field pattern, that is ***the molecular image*** of the particular VOC molecule (1). This image would be sent together with all the other presented molecule images to a collection point *the glomeruli* and electric field filter station, *the olfactory bulb* (20,21).

Its very difficult to describe all the system functions of the olfactory bulb and what it does with all the electrical signals that reaches its input areas *the glomeruli.* It is possible to use a metaphor with a technological system that readers from the engineering disciplines are more familiar with, a radio/TV station (31).

The olfactory bulb works much like a radio/TV station that listens in on their antenna signals (the ORCs) and receives, records, filters, modifies, edits and broadcasts a pulse basis bring in to the indoor environment as fruit, shampoo, dry cleaned clothes, perfume, glue and personal belongings (9). Our severe conclusion can be that we have a lot of “raw material” for chemical reactions indoors. Chemicals in soil water are indicators on that.

¤ ***favourable indoor air conditions*** are important from two aspects. First of all it gives the humidity, temperature gradients and vortex flows (10) that stimulates gas reactions, the mixing conditions and necessary transfer of “raw material”. Secondly the indoor air conditions would stimulate exposure from emissions if there are passive airflows that creates several transportation lines to the nose. Active ventilation systems and fans in vacuum cleaners, computers and other electrical equipment are other sources for air streams and also for transformation of chemical compounds, like ozone from copymachines.

A high dampness rate increases the likelihood of surface reactions because aerosols have a large surface-area-to-volume ratio and water is also a soluble for a lot of VOC. Gases like ozone (1 1), NOx and sulfurdioxid can stimulate reactions(9,12). They can enter via ventilation air and mix with the indoor air (6).

If we want to confine our analyses about interactions from VOC in the indoor air it is of great importance to separate VOC emissions and exposure of VOC. As an example we can consider the VOC benzene which is a carcinogenic. Sources for benzene emissions in the USA originate to 82 % from automobile exhaust, compared to individual activities 3% and tobacco smoke 0.1% (6). But when you look at exposure, automobile exhaust is only 18 % compered to individual activities 34 % and tobacco smoke 45 % (6) .

That means that VOC molecules will be VOC emissions through processes depending of building physics and than transformed to VOC exposure through chemical reactions and a VOC intake when it reaches the human body receptors. Controlled measurements can be done concerning exposure in reaction chambers.

Indoor air conditions can be decisive for gas reactions to occur. It can be compared with the conditions in a reaction chamber. There is a need for input systems, circumstances that supports molecular meetings and output systems that distribute the resulting compounds out from the reaction environment and in to the nose.

¤ energy will stimulate chemical reactions. One important energy source is free convection heat transfer from radiator surfaces to the surrounding indoor air (13). The energy transfer due to radiation, heat conduction and air movements close to a surface is fundamental knowledge in building physics and gives us an established theoretical background for calculations of energies necessary for chemical gas reactions in a simulated reaction chamber.

Electric coil surface radiators can have surface temperatures outside exceeding +90°C inner coil surface temperatures exceeding +200°C (2000 W radiator) under production of a continuous +70°C airflow. Continuous free convection heat transfer in the interval +60°C to +200°C from different kinds of electrical heaters, lamps and other sources means that we have enough energy for very advanced chemical gas reactions to take place.

Olfactory perception requires that the involved indoor air molecules have certain specific characteristics. Reaction products must fulfil certain demands concerning the surface structure of the molecules to be able to efficiently interact with sensors in the nose.

Its not possible to give a complete list of chemical characteristics that would be harmful for the individual, but certain groups of chemicals has been proven to interact as odours.

Among these groups we can point out four that interacts with man. Substances that are characterized as aromatics, short fatty acids, terpenoids and camphor (21).

frequency modulated electric magnetic field signal (18), primarily through fixed lines (19) to a certain number of receiver stations out in the neighbourhood (stations in the brain).

The information programs that will be sent from the olfactory bulb to different parts of the brain, are trigged off by the VOC molecules in the nose. The programs takes in to account a lot more information than just the molecular image. This information programs wiii contain all the iatest information that the brain need to take proper action, due to changes in the indoor environment.

The information program is transmitted first of all to thalamus which is the brains central command, which control all the outside environmental input to the brain, but the signals from the olfactory bulb is an exception because the bulb can also transmit to three other important secondary control centres of the brain, without passing thalamus, which is very unusual.

Since this paper tries to show some of the implications that signals originated from VOC molecules can lead to, its important to follow the olfactory information to the receiver stations and see what happens with the information presented.

The olfactory message of VOC is transmitted ***to aii four centres*** as foilows:

- ***the thalamus*** which is the brains central command that processes and distributes almost all sensory and motor information going to the cerebral cortex (15).
- ***the pyriform*** cortex control centre; the main olfactory discrimination region where sensory signals are distributed to other centres (20)
- ***the amygdala*** control centre; exercises a major control over the endocrine system, in particular hormones from *hypothalamus* and emotional expression (20).
- ***the hippocampus*** control centre; responsible for storing short term memories and preparing for long term storage (21).

We can foilow the chemical image pattern that was produced by the original VOC molecule aii the way to the ends and outputs of the human olfactory system.

A hypothetical VOC molecule can through the human olfactory system, that can percept this molecules, implicate: a release of hormones, influence emotional expressions and induce memory changes in the brain, among other things. The code for the original chemical image patterns from different VOC molecules are unknown but there are several theoretical models that could be of use for further scientific investigations.

4. Theoretical models for perception of VOC in humans

To percept a VOC molecule means that the olfactory bulb has to respond to the message of that molecule and also to commands from the central brain. The message in the molecular image depends on the functional groups of the molecule, Several theories tries to explain how the molecular image is read and coded by the receptors.

Molecule/Receptor Resonance Theory (21)	Thermodynamic Activity Theory (21)
Chromatographic Theory (21)	Membrane Penetration Theory (2 1)
Stereochemical Theory of Olfaction (21)	Immunochemical Theory (21)
Hansch Parameter Theory (21)	Molecule Image Analyses (1)

The VOC molecules active domain must in some way react with a receptor protein .

There are at least 1000 different olfactory receptor proteins, each encoded by a gene of their own. Smell can be blends of molecules. That means that the possible combinations are numerous. It is estimated that we can distinguish between 5000 different odourants and that we can detect considerably more (16).

There is also a possibility that the signal would interfere with the endocrine system, because there are interconnections between the central nervous system, the endocrine system and the immune system (22,23,30).

Even though that hormones are signal molecules in an internal signal system of the body and would be transported in the blood vessels, this process is still controlled from amygdala. It is also possible for amygdala to get signals through the nervous system (15).

That means that the implications on hormones concerning the perception of VOC would be that central parts of the command centre in the brain could get neuron signals from VOC perception, at the same time as it reaches feedback from the hormone system. Its not clear which signal that would dominate the following reactions but there is great need of research in this matter because this type of signal interference and disturbing interaction would be a primary effect of interaction between man and VOC in the indoor environment.

5. A sequential theoretical study of possible VOC effects on humans

We have seen that VOC compounds can be detected by the human olfactory system and cause an effect on the body. There is an acceptance that this can cause the sick building syndrome (SBS), in combination with poor ventilation (24,25). There is also an established increased risk for asthma in damp buildings with newly painted indoor surfaces (11, 25).

The intention of the following paragraph is to present a sequential theoretical study , a chain of events, just as a creative model and as an indicator of one possible process pattern that shows the interaction between building and man. This process pattern is not proven in any clinical study but might give us some clues of which kind of VOC effect we can expect from interaction through the olfactory system and how its possible to plan a study.

¤ a person is working in an office room near a corridor with newly painted walls and new carpets, in the end of the corridor is a special room for smokers.
¤ the paint and the carpets has been there since 6 months and there is no smell , TVOC measurements shows that there is TVOC concentrations, formaldehyde and benzene present in the indoor air but much lower than the established limits (8, 26, 27).
¤ the paint still fumes low emissions of DEHP and some unidentified VOC (8).
¤ the ventilation system is not working properly because air from the corridor goes in to the office room under the door and transports in to a warm radiator stream along the wall and the window. The air flow rate is bad because of bad maintenance. NO_x and ozone from cars in the street is present in the ventilation air.
¤ the corridor and office floor has been cleaned with causticsoda that has leaked in under the carpets and reacted with the formaldehyde emissions in the floor plates. Formic acid is produced (28) and it follows the airstream together with the other emissions into the office room.
¤ the radiator surface heats the gas molecules and a reaction starts that produces new VOC molecules with a characteristic planar form and an aldehyde group (12).
¤ when the heated airstream passes the window surface the gas molecules dissolves in the aerosol from humidity and transports to the persons nose (10, 12).

¤ the olfactory system in the nose detects the extremely low concentration of formic acid because it is an alarm pheromone and also the blend of VOC molecules and transmits the molecular images of the molecules to the olfactory bulb that compares this new signal pattern with information from the olfactory memory (1, 20, 29).
¤ the molecule image pattern mimics signal molecules that means that a serious (in an evolutionary sense) dangerous situation is coming up outside the body. The brain is fooled, because it is not used to this chemicals in the indoor air environment.
¤ all this actionsignals are sent to amygdala that trigg a lot of hormone activities in the body which react as in a stress situation (30).
¤ the person in the office room feels sick and the eyes starts to run.
¤ this procedure repeats it self every morning an, the building is classified " sick building"
¤ the person in the office would be sensitized against the particular VOC combination and each time the molecule image occurs, the olfactory memory sends out the same defence action program to the body.
¤ the allergic reaction later develops to an asthmatic syndrome.

This situation have never been proven, but we can study the possibilities for each step to occur in reality. There is a lot to reflect on in an interdisciplinary way. To be certain of that this scenario is possible to communicate to concerned disciplines, there is a need of a language of VOC, that can describe it. The purpose of the described scenario was to stimulate a discussion in a new context to learn more about VOC interactions and signals.

6. The signal process approach to VOC interactions

The main part of the olfactory system belongs to the brain which uses electro chemical signal patterns (19, 3 1) for daily process work. Treatment and transmission of chemical stimuli is standard procedure in the brain. A metaphor can be useful. If we take all trees in the amazon jungle (about 100 billions) and connect all leaves on the trees with each other by wiring (34), add that there are also possibilities for all trees to send signals to each other by radio transmission (3 1). Then you have an estimate of the complexity of the brains electrical signal system.

The brain is also a self organized system that adapt and changes the connections all the time as a response to outer and inner signals (3 1). The signal pattern is spatiotemporaled which means that the signals are distributed in space and time simultaneously (32). There is no established method to analyse all this electric signals at the same time but one tool that has been suggested is mathematical fractal theory (31).

A process of signal handling need information storage for new signals and there is in fact an olfactory memory (smell memory) that is located in the olfactory cortex of the brain which has connections to other parts of the memory in the brain (2, 21. 33).

An original perception and registration of VOC molecules in the olfactory memory can release picture memories the next time this VOC reaches the nose, which points to a connection with other parts of the brain (20). The brain is an excellent instrument to handle electrochemical input with, but its as good as its inputs. If the input is a new signal or an old recognizable signal, different action takes place.

A possible way to understand the interaction and the effects of signal interference of chemical compounds on humans, can be summarized by the following hypothesis:

¤ ***VOC molecules are chemical signals*** in the indoor air approaching the body
¤ ***VOC blends are signal patterns*** that involves information perceptible but ***misinterpreted by the bruin***
¤ Hormones and interlekuines are also chemical signals but they act in principles inside the body and act only on the command of the programmed and tuned brain.

The olfactory part of the brain pick up and translate this VOC signal patterns from the outside and transfer the information according to the program and tuning it is used to, since millions of years of interaction with the environment outside the body (1,20,29).

Since VOC molecules in an evolutionary way often are new man-made chemical signals, with active chemical domains similar to signal substances traditionally used by living organisms, the brain can be fooled and take improper action (1,20,29). It would misinterpret what is going on outside. The wrong action messages in form of neuron signals, hormones and interlekuines reaches different parts of the body ***and we feel sick.*** The body reacts with normal defence actions but towards the wrong signals. This signal approach can also give possible solutions to the increasing allergy and asthma rates and to SBS.

7. Conclusions

What are the conclusions from this VOC signal molecule journey and the signal process approach ? Would healthy buildings be constructed by fractal mathematicians and endocrinologists just to be sure that we can avoid SBS effects on man ? The answer to this is no. Skilled engineers and builders know how to construct and build high quality buildings, but it is not always possible to push this ideas through **because** of economical reasons.

However it is possible that the process of interaction and the answer to why people become ill from certain carpets or solvents in a composite building component, might be solved by fractal mathematicians.

In the meantime, dampness and sources to oxidation which supports chemical reactions, can be reduced. Interdisciplinary research can be done on signals and interaction between building and man. Investigations of houses where people are healthy can be performed. Increase the scientific communication and translate the results between the disciplines. Investigate, find and eliminate the worst well known chemical compounds ,

My hope with this paper is to stimulate an atmosphere of mutual respect between experienced builders, building engineers, physicians and theoretical scientists, within the frame of interdisciplinary cooperation .

Computer-Based Performance Modelling Tools for Natural Ventilation

Y. Li, J. Symons, A. Delsante and L. Chen
Advanced Thermo-Fluids Technologies Laboratory
CSIRO Building, Construction and Engineering, Melbourne, Australia

Abstract

Natural ventilation provides an attractive energy-efficient and sustainable ventilation mechanism following the emerging political and community pressures for Ecologically Sustainable Development. Performance modelling for natural ventilation is the first step towards its reliable control and design, which is critical for a much wider recognition and applications. Such performance evaluation and design tools are required by consulting and services engineers, building designers and architects.

The purpose of this paper is to outline the new design tools becoming available for the development of improved natural ventilation and energy saving strategies and how they are being applied to a variety of realistic projects.

The paper first reviews the natural ventilation technology and associated design issues in terms of flow pattern and ventilation flow rate. There are two basic air flow patterns in naturally ventilated buildings. Computer-based design tools such as analytical methods, multi-zone approaches (e.g. CHEETAH/MIX2.0), and computational fluid dynamics methods (e.g. VentAir) are described with different levels of design requirements and complexity of the design.

In partnership with Australian industry, the tools described in this paper is being applied on (innovative) ventilation projects, prediction of building thermal and ventilation performance at the design stage, analysis of indoor air quality, innovative ventilation schemes etc. The application of these modelling tools for three Australian building projects including an one-zone enclosure with natural ventilation, a multi-zone enclosure with natural ventilation and a multi-zone enclosure with mixed-mode ventilation, is described.

It is concluded that energy and ventilation design tools are improving, and becoming more readily available to the building and building services designer. As improved ventilation and energy strategies become available, they are playing an important role in ecologically sustainable development for building applications. Careful engineering design analysis has proven to be a cost-effective means of avoiding many building energy and ventilation problems. Application of these design tools has proven to be particularly effective for difficult or highly innovative building projects.

Keywords: Natural ventilation, design tool, modelling, application, flow pattern

1. Introduction

The emerging political and community pressures for Ecologically Sustainable Development will drive the need for more energy efficient buildings and improved building heating, cooling and ventilation strategies. Natural ventilation has been one of the technologies being considered, although quite often its effectiveness can only be achieved when used together with passive cooling and controlled properly. In some cases, supplementary mechanical ventilation systems are required and the ventilation system is said to be functioning in a mixed- or hybrid mode. Computer based design tools can play an important role in optimising design of natural ventilation to achieve the required energy savings and ventilation effectiveness. These tools range from simple programs based on analytical solutions, multi-zone numerical programs to much more computer-power-demanding computational fluid dynamics software,

New generations of energy and ventilation design tools provide faster and therefore cheaper analyses at the design stage, added confidence in system performance, and the opportunity to improve the design rather than fix the problem after construction. These design tool advances are primarily of interest in difficult natural ventilation problems - large building spaces, tall spaces, high heat loads, semi-enclosed spaces, partly air-conditioned, innovative building designs, some tunnels etc. Sophisticated analyses are usually not required for straightforward building projects which are currently being dealt with using existing design practices.

The purpose of this paper is to outline the new design tools becoming available for the development of improved natural ventilation and energy saving strategies and how they are being applied to a variety of realistic projects.

2. Natural Ventilation

2.1 Why Ventilate Naturally?

The question should really be asked is that if natural ventilation works, why ventilate mechanically. Natural ventilation is an old technology and can be found in many ancient cultures. Natural ventilation is also a clean, energy-efficient, and environmentally-friendly technology. However, its function is dictated by outdoor climate and building use in most situations, which means that the system might not provide a suitable thermally comfortable environment and might not provide sufficient ventilation at extreme conditions. This is partly due to the governing mechanism of natural ventilation and the uncontrollable outdoor climate, but it is also important to realise that many old and conventional designs were based on experience, rather than scientific approaches.

In Australia, the vagaries of weather make it difficult to predict or guarantee natural ventilation performance, and this alone will preclude the use of natural ventilation for many commercial buildings requiring guaranteed levels tightly specified thermal performance. However, the temperate weather conditions over many parts of Australia make natural ventilation an attractive option for many built environment applications, particularly where large building spaces are involved. For many building applications, mechanical ventilation systems are often impractical, or financially unattractive. For these applications, natural ventilation can provide good ventilation performance with low installation costs, no operating or maintenance costs, and operational reliability. The benefits from natural ventilation are now being recognised and it is being applied in many commercial and industrial applications.

Knowledge of fluid mechanics, turbulence and heat transfer has improved our understanding of natural ventilation. In the last twenty years, there have been some excellent efforts to develop simple design tools for natural ventilation. In recent years, more complicated tools have also been developed for determining ventilation flow rate and ventilation flow pattern. In particular, there have been a number of international joint efforts to develop design tools.

Engineering knowledge in natural ventilation design has also been enriched. This can be shown by a large number of innovative designs, for example, [1,2]. It is now possible to simulate quantitatively the natural ventilation performance before the system is built. Effective measurement techniques such as computer-based measurement systems and tracer gas methods are available for post-construction performance monitoring.

Above all, it is the emerging political and community pressures for Ecologically Sustainable Development that will drive the increasing use of natural ventilation, as pointed out in the introduction.

2.2 Mixing Ventilation Flow Pattern

Before describing performance-based design tools, it is necessary to revisit two basic flow patterns in naturally ventilated buildings. The mixing ventilation flow pattern generally occurs in buildings where wind-induced natural ventilation dominates. The wind-induced flow enters the building, interacts with the thermal plumes above the heat sources and other flow currents, and forms large recirculation cells. This flow is essentially similar to that found in a fully-mixed mechanical system as used in most building applications. This flow pattern mixes the incoming outdoor air with the room air and provides uniform temperatures and pollutant concentrations throughout the room. A cross natural ventilation system can generally provide such a flow pattern.

This flow pattern is generally easy to consider in a simulation program. In fact, most existing thermal performance and multi-zone ventilation programs assume that air temperature in each zone is uniform. However, wind-induced ventilation is also very difficult to simulate, due to the fundamental difficulties in predicting wind-induced flows around buildings. Mixing natural ventilation flow pattern is not common in commercial and residential buildings, but very common in some industrial and agricultural buildings. This flow pattern is certainly dictated by wind conditions.

2.3 Displacement Ventilation Flow Pattern

This flow pattern is generally associated with thermo-buoyancy-induced natural ventilation. The system introduces cool fresh air at floor level. Internal heat sources within the room warm the air which rises and stratifies. The heated air pushes the room pollutants upwards which are then exhausted to the atmosphere. This is a natural stratification process, providing fresh cool air at floor level, and mixed warmer air at the ceiling. The height of the interface between the fresh and polluted air is determined by the air flow rate, which is in turn determined by the thermal buoyancy force.

In buildings with a displacement ventilation flow pattern, there is generally a vertical temperature gradient. Surface radiation heat transfer is also important. The modelling problem is how to predict thermal stratification and the effect of thermal stratification on heat transfer and ventilation.

In practical situations, the flow pattern is generally a mixture of the two basic flow patterns.

3. Examples of Design and Analysis Tools

We have attempted to address the need for reliable natural ventilation design tools through its development of analytical solutions, multi-zone modelling and CFD modelling.

3.1 Analytical Approaches

Natural ventilation is a process of both heat transfer and fluid mechanics. There are two categories of analytical solutions, those for when the indoor air temperature is known and those for when the indoor air temperature is not known.

A well-known example of the first category solution is that for a single-zone building with two unequal area openings separated vertically by a height. Recently, we have been able to derive a solution for multi-zone buildings where each zone has effectively two ventilation openings. These solutions can be applied in many realistic situations where the problem can be simplified. These solutions have been converted to a number of successful design guidelines see for example, [3, 4].

In the second category are solutions where thermal buoyancy works alone, the most well-known solution being the emptying filling-box model where a single-zone building is considered. In this model, the enclosure is divided into two temperature zones, the bottom zone with cold and dense outside air, and the top with warm and lighter air. This model has recently extended to an emptying air-filling box model in which the bottom zone air can be heated by the warmer floor, which is heated up by surface radiation from the even warmer ceiling surface. A similar analytical solution can be derived for multi-zone buildings where each zone has effectively two ventilation openings. All the walls and partitions have to be assumed to be adiabatic.

These analytical solutions can be used not only for design purposes, but also for evaluation of the zonal modelling approaches.

3.2 Zonal Modelling - CHEETAH/MIX2.0

Zone modelling programs assume certain areas (zones) of a building to be fully mixed or have a vertically linear temperature profile. These programs are computationally fast, and enable overall ventilation flows to be calculated, without any spatial information within each zone. The MIX1 .O (Multi-cell Infiltration and eXfiltration) program was first developed by Li and Peterson [5]. In MIX1.0, an erroneous interpretation of the physical meaning of the concept of internal pressure in each zone prevented the calculation of bi-directional flows between zones. Recently, we [6] developed a consistent pressured-based formulation for natural ventilation of single-zone and multi-zone buildings with multiple openings . The formulation is made easier to implement by introducing an auxiliary concept of external pressure, which allows us to present all the formulas in a generalised form. The formulation was implemented in MIX2.0 [7]. Multi-zone situations considered in MIX2.0 include vertically interconnected zones, and horizontally interconnected zones with the same or different heights.

In MIX2.0, the building geometry and ventilation openings between each zone and outdoors are specified, flow rates are calculated as a function of pressure difference across each opening, and a mass balance and iteration applied to calculate the absolute pressure in each zone and air flow rate between each zone. MIX2.0 program considers fully the bi-directional flows through all large openings. These bi-directional flows are common in large commercial and industrial buildings, and must be modelled reliably if natural ventilation flow rates are to be predicted with reliability.

In order to compute the natural ventilation air flow rates through buildings, ventilation programs like MIX2.0 need to know the indoor temperatures within each building zone in order to calculate the respective pressure differences. Indoor temperatures however are dependent on the ventilation rates. To overcome this conundrum, our thermal analysis programs CHEETAH and MIX have been integrated to simultaneously compute building thermal performance, energy use and natural ventilation performance. The result is a powerful building thermal analysis program. CHEETAH is a program developed at CSIRO to calculate heating and cooling energy requirements for buildings, including housing. CHEETAH's simulation engine was chosen by Australia's Commonwealth, State and Territory governments as the most appropriate program for a national home energy rating scheme [8].

3.3 CFD Modelling - VentAir

While zone modelling provides rapid computation of air flow rates, zone temperatures etc for buildings, the spatial variation of air speeds, temperatures, contaminant concentration, and other air quality parameters are not available from zone modelling. Computational Fluid Dynamics (CFD) is now being increasingly used for this purpose.

In a CFD method, the building is divided into a large number of small elements or sub-volumes. The conservation equations for mass, momentum and energy are applied or discretised in each element or sub-volume. The resulting system of the linear equations is solved to obtain velocity components, temperature, concentration and pressure at each grid point. Cooling or heating load programs with various levels of complexity can be used to provide thermal boundary conditions for CFD, while CFD can provide detailed information such as air temperature distribution and convective heat transfer rate at solid surfaces for a cooling or heat load program. A well-integrated program allows the prediction of detailed air flow pattern, ventilation flow rates and detailed air temperature distribution.

There are at least two possible approaches to study the interaction between indoor and outdoor thermal environments. First, the computational domain can be enlarged to include the outdoor region around a building. Second, the computational domain is limited to the indoor domain. We prefer to use a pressure boundary condition at all external openings, and the wind pressure can be included.

There are many commercially available CFD programs available for the solution of fluid flow problems . In CSIRO, our finite volume CFD program Ventair (e.g. [9,10]) has been used.

4. Case Studies

The above ventilation and energy saving strategies have recently been applied to a number of innovative building projects. In each case, computer analysis and design tools have enabled ventilation and energy performance to be predicted and optimised for the intended purpose of the building. Three representative applications of this research are included below.

4.1 A One-Zone Enclosure - Sydney Fruit Market

This was a straight forward project to assess the likely contaminant levels from truck exhausts if the loading bays at Sydney's Flemington Markets were covered with a roof, Figure 1. The consultants Sinclair Knight Merz needed to assess the distribution of exhaust gas contaminants under the covered area.

The loading area was modelled using both CHEETAH/MIX and VentAir. Exhaust emissions were modelled for **24** trucks with engines idling, and distributed throughout the loading area. The distribution of exhaust gases was calculated for various design options in order to maximise the air quality. The design options included height of the roof, roof ventilator design and location, mechanical ventilation options, etc. The analysis showed the worst case scenario to be for no wind.

The adopted solution comprised a purely natural ventilation system with exhaust gases purged through roof ridge vents and the gap between the new roof and the existing buildings. The air change rates predicted by CHEETAH/MIX and Ventair agree well. A typical temperature distribution as computed from VentAir is also shown in Figure 1.

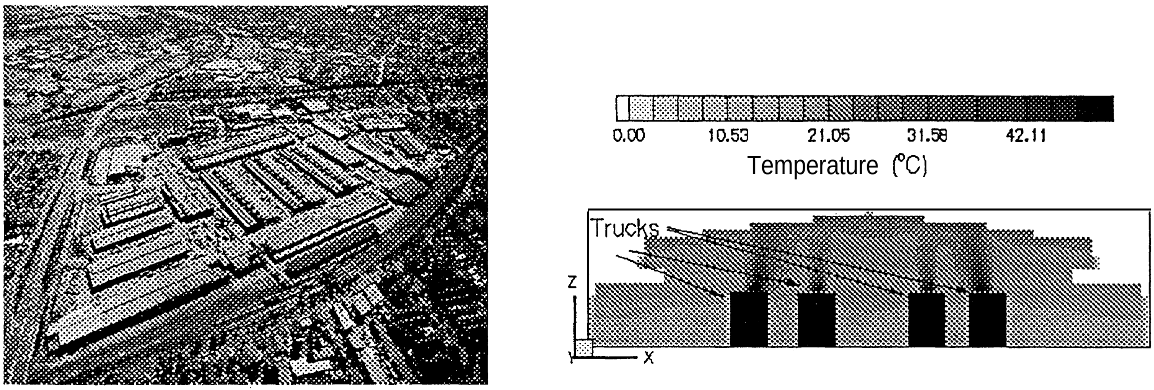

Figure 1: Sydney's Flemington Markets (left) and calculated air temperatures (right).

4.2 A Multi-Zone Enclosure - Copper Smelter

H H Robertson were engaged by Western Mining Corporation (WMC) to analyse the natural ventilation performance of a proposed copper smelter building to be constructed at Olympic Dam in South Australia. WMC had earlier experiences with excessively high operating temperatures in an existing smelter building at that site. The proposed building was geometrically complex and comprised multiple and interconnecting floor levels, with two main building areas, a casting building opening into the taller furnace building. The plant comprised several furnaces, molten metal launders, off-gas ductwork and many other heat sources. Total power dissipation into the building was about 13 MW. The emission of process gases required local ventilation systems in several strategic locations in the building. In this situation, natural or mechanically forced ventilation are the only cost effective methods of minimising the indoor air temperatures. The main concern was to minimise the indoor air temperatures in summer for the plant operators, under conditions where outside ambient temperatures can exceed 42°C.

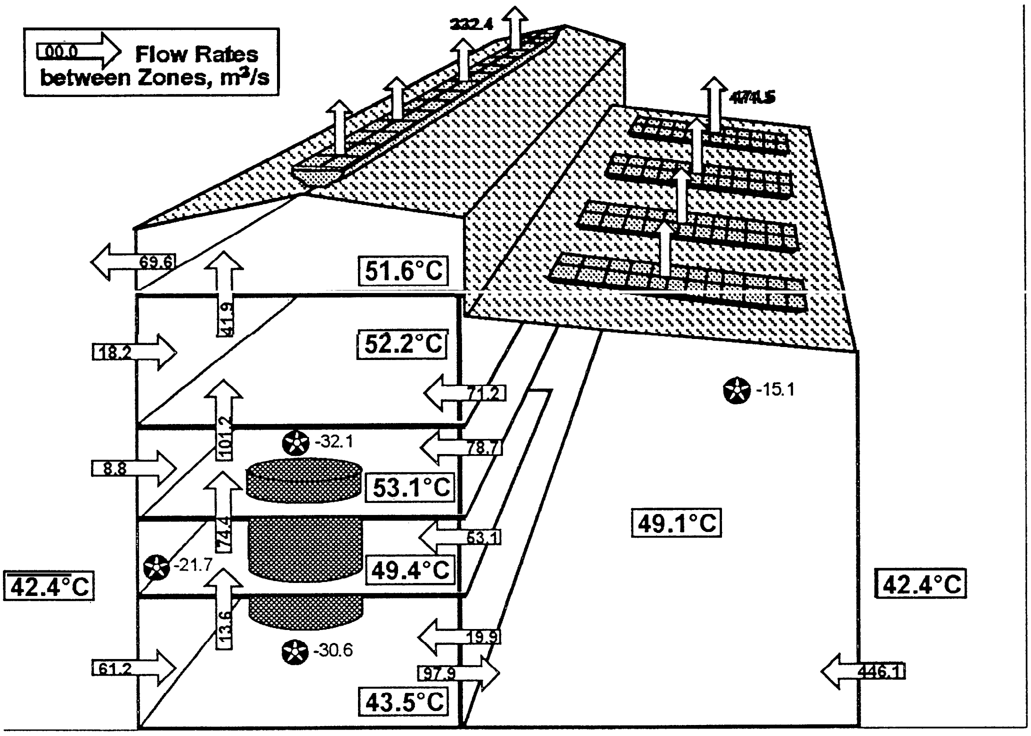

Figure 2: CHEETAH/MIX results for the Copper Smelter.

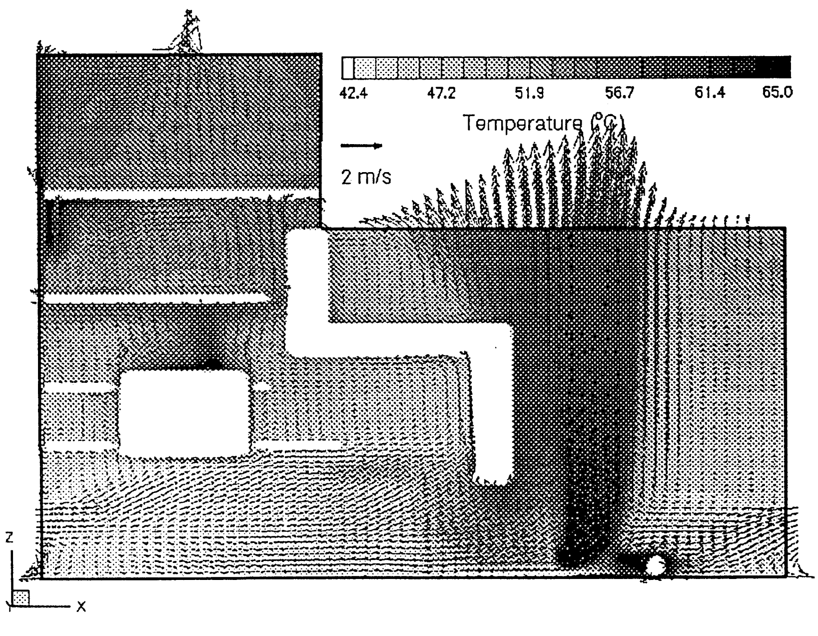

Figure 3: VentAir Calculation of Smelter Air Temperatures and Velocity for one vertical plane.

The first stage of the analysis involved CHEETAH/MIX to calculate the building envelope performance, indoor air temperatures, infiltration, exfiltration and air flow rates between all openings in all zones. Many design options were compared in order to minimise the building construction costs, and still achieve the required indoor operating conditions. Figure 2 shows the results of the zone modelling for one design case. The final solution was achieved using a purely natural ventilation system.

The second stage of the analysis involved a computational fluid dynamics analysis of the entire smelter building to determine the local temperature and air flow velocity variations. The analysis involved 500 000 grid points in VentAir. Figure 3 show one vertical section through the building from this VentAir analysis.

4.3 Mixed-Mode Ventilation - Manly Hydraulics Laboratory

This building includes a number of open floor plan laboratory and administration spaces, in a series of stepped areas down the sloping site. The NSW Dept of Public Works and Services has proposed a very innovative building design which is intended to provide summer cooling by natural ventilation. The building incorporates a plenum under each floor level. The plenums communicate with the occupied space above via air registers. Solar chimneys are added to distribute the exhausted air flow uniformly over the length of the building, and enhance the air flow rate through the entire system. Fans are installed to supply air to the plenums at night to provide night cooling when necessary. A schematic of the building concept with the envisaged air flow distribution is included as Figure 6.

The program CHEETAH/MIX were used to determine the thermal and ventilation performance of the building which was divided into 27 zones for the analyses. The analyses showed a number of unexpected ventilation flow rates and air flow patterns. The key problems to be overcome were the need to maximise the natural ventilation flow rates in order to provide sufficient cooling to the building, and to maintain a uniform upward air flow through the plenums to the rooms and out through the solar chimneys. It was found that in certain circumstances, air could flow down the lower solar chimneys, through the building and out through higher chimneys. Prior to the availability of programs such as CHEETAH and MIX, it would not have been possible to predict these abnormal flows, and therefore be able to minimise the problems at the design stage. The modelling work allowed us to advise on air flow control strategies, cooling energy savings and improved design options.

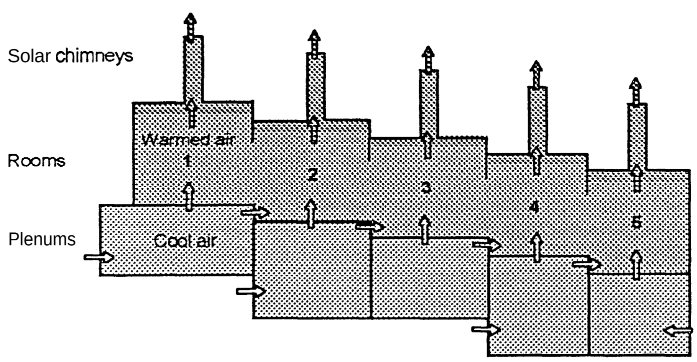

Figure 6: Schematic of the Manly Hydraulics Laboratory.

5. Conclusions

There is increasing interest in natural ventilation as an energy saving alternative to building heating, cooling and pollutant removal. Energy and ventilation design tools are improving, and becoming more readily available to the building and building services designer. They are playing an important role in ecologically sustainable development for building applications. Careful -engineering design analysis has proven cost-effective means of avoiding many building energy and ventilation problems. The computer-based performance tools have been used in the development of new energy and ventilation technologies. Application of these tools has proven to be particularly effective for the difficult or highly innovative building project.

Healthy and environmentally compatible building. materials, report on a German project

E. Mayer, K. Breuer
Fraunhofer -Institut fur Bauphysik, Holzkirchen, Germany
(Leiter: Prof. Dr. Dr. h.c. mult. Dr. E. h. mult. Karl Gertis)

Abstract
"Healthy and environmentally compatible building materials" is the title of a joint German four years project with a budget of DM 5 million. The Fraunhofer-Institute for Building Physics and the Institute for Toxicology and Environmental Hygiene at the Technical University of Munich are running the project. The purpose of the project is to promote the manufacture and widespread use of healthy and environmentally compatible building materials. Using the tools of chemistry, sensory evaluation and toxicology, the researchers develop evaluation criteria, measuring procedures and a data base for a wide diversity of product groups.
Keywords: Building materials of low emission, chemical measurements, sensory measurements, toxicological measurements

1 Introduction, aims of the project

For years producers and users of building products have been increasingly uncertain as regards the effect of these products to people's health and the environment. At the present time, a great skepticism even towards traditional and proved building materials can be observed. There is a lack of research and test results capable of overcoming or removing this uncertainty. A way out is supposed to be shown by the current joint project of the Fraunhofer-Institute for Building Physics (IBP) and the Institute for Toxicology and Environmental Hygiene at the Technical University of Munich (ITU), in close cooperation with industrial associations and companies. The project offers companies the possibility to provide themselves an additional competitive advantage as a result of the examination of their products (which will also be due to EC building product regulations). This advantage can be a achieved by pointing out the special features of their building products with respect to health and environmental compatibility.

The aims of the project are:

- The development, validation and testing of a standardized method for chemical, sensory and toxicological examinations of building products
- The use of scientifically approved and recognized standards and criteria for evaluation how healthy and environmentally compatible building materials are as well as for limitation of abuse by means of doubtful so-called building-biological examinations
- The active support of further development and introduction of Europe-wide standardized examination methods for this
- The establishment of a data base for documentation of the quality of building products, for supporting the planning of healthy and environmentally compatible buildings and for further developing the building products in cooperation with the European Data Base on Indoor Air Pollution Sources in Buildings [1].

2 Development of the chemical and sensory methods

Chemical and sensory matters are experimentally examined by IBP. In this respect, experiments with building products and building parts are carried out in a test chamber, with practice-oriented and building physical edge conditions being considered. Evaluation as regards quality and quantity of the substances emitted into the test chamber atmosphere is done by means of chemical analysis on the one hand and by the use of human olfactometric processes on the other hand.

2.1 Chemical methods

All over Europe, constructions of emission chambers are different. Differences are particularly obvious in the selection of materials, where two basic types can be observed: chambers made of refined steel and chambers made of glass. Our own tests using miniature chambers (50 ml - 30 1) have shown that especially with respect to the chemical fine analysis high material standards are to be defined so that even polar compounds can be proved in the chamber air with a satisfying re-detection rate. Electropolished refined steel has proved to be very advantageous.

The test chamber (with a volume of $1m^3$) used purely consists of electropolished refined steel to minimize wall effects and keep the re-detection rate at a high level. Furthermore, it can be thermically dosed. Defined settings and their tolerances can be seen in table 1. Apart from the classic $1m^3$ chamber type, which is chiefly used for the simulation of building physical parameters and installation situations (practice oriented conditions), IBP is already provided with several small-chamber systems. These are used for pre-experiments to define standards for larger emission chambers. For olfactory examinations a method has been developed which makes it possible to reproducibly measure odorous annoyances by means of test chamber examinations.

Table 1 Range of capacity for 1 m^3 emission chamber

Settings	range of capacity	range of tolerances
temperature	+10 °C bis +130 °C	±0,3 K by time ±0,5 K locally
change of temperature	cooling: ca. 0,3 K/min heating: ca. 0,4 K/min	not defined
relative humidity dew point	30 % R.H. to 95 % R.H. +5 °C to +88 °C	±1% locally ±3% by time
air velocity	0 to 0,5 m/s	±0,1 m/s locally and by time
desorption	230 °C to 260 °C at n= 5 h^{-1}	not defined
re-detection	> 80 %	not defined
air exchange	0, 0,1 to 2 h^{-1}	continously adjustable
chamber density	up to 1000 Pa compared to outdoor pressure	0,001 % of chamber volume per minute

During a first qualitative step high emission factors are intentionally generated under "worst-case conditions" like high temperatures, extreme loading of miniature emission chambers and no or a very low ventilation etc. These conditions which are not usual in practice lead to high concentrations of volatile and medium-volatile compounds in the chamber air, which facilitates identification of the compounds. In subsequent quantitative work steps the chamber air is, now under practice-oriented conditions, examined for the components found during the qualitative analysis. VOC's are concentrated on appropriate adsorbents and gas-chromatographically analyzed via thermodesorption. Aldehydes and ketons are collected via dinitrophenolhydrazine cartridges and quantified as a DNPH-derivate by means of liquid chromatography. Parallel to the quantitative analysis of single components the total emission is determined as a toluene equivalent.

2.1 Sensory methods

One of the aims of this package of tasks is the development of a method to find olfactory thresholds. In contrast to the commonly used method to detect odorous annoyances, comparatively reproducible test results are to be expected with this method. It requires the use of an olfactometer which allows low degrees of dilution.

With a good reproducibility this olfactometer can do with little sampling material and operates in accordance with the method of static gas dilution with the use of head-space bottles. As an odorless gas nitrogen or synthetic air is used. The head-space bottles serve as sampling and dilution containers at the same time. After the head-space bottle with the sample has been inserted into the olfactometer, the pressure within the head-space bottle is doubled and then released via a nose mask. This procedure is repeated until a test person does no longer smell anything. The value of the olfactory threshold is calculated from the weight of the sample or the volume of the head-space bottles and the number of extractions. The testing method can be extended by special sampling techniques. The head-space bottles can be evacuated, and samples can be taken from the emission chambers in situ. An operational test of the olfactometer lead to the results shown in table 2.

Table 2 Olfactory thresholds found by means of olfactometer, partially according to [2].

solvent	injected volume [µl]	concen-tration [mg/m³]	number of extractions	experi-mental threshold value [mg/m³]	olfactory threshold values in literature [3] [mg/m³]
Toluol	05 3	4360	8	17	0,6 to 153
Ethylacetat	10 3	9000	6	141	0,2 to 183
Ethanol (2 % Cyclohexan)	10	7900	6	123	
Ethanol	1,0	7900	3	988	19 to 672
Methylethylketon	1,0	8060	6	126	30 to 80
Isopropanol	10 3	7850	4	491	80 to 250
Fuel 80/1 10	10 ,	7160	4	448	3300
Xylol	05 ,	4325	10	4	1 to 100
Isopropylacetat	10 ,	8700	7	68	140
Methanol	10 ,	7900	2	1975	6,6 to 7800
n-Propanol	10 ,	8035	9	16	30 to 250
n-Butanol	10 ,	8100	14	05 3	0,36 to 77
n-Butylacetat	10 3	8820	11	4	0,35 to 48
Methylacetat	1,0	9270	4	579	145 to 550
Aceton	0,5 / 1,1	100 / 210	2 / 1	31 / 46	0,93 to 1862

In order to ensure testing methods to be practice oriented from a building physical point of view, the following parameters have been defined as testing and measuring factors:

- temperature
- relative humidity of the air

- surface specific ventilation rate
- flow velocity
- time of measuring

The interpretation of these parameters to a particular situation of measuring must include the respective inside and installation situation of a building product. With regard to -present norms and particular room climatic examinations the above parameters have been determined for initial tests in accordance with table **3.** The flow rate, which determines the surface specific ventilation rate, should not vary by more than ± 3 %. TVOC concentration should not exceed a value of **10** µg/m³ in the supply air (TÄ = toluolequivalent) or be below 2 µg/m³ for individual components. Some of the results are given by means of emission factors (EF). To this end, the average of two parallelly measured VOC concentrations is calculated:

$$EF = C_x (n/L)$$

EF = emission factor µg/[m2h]
C_x = chamber concentration of VOC,, µg/m³
n = ventilation in the chamber, h^{-1}
L = loading factor, m^2/m^3

The chemical analysis of volatile compounds from the atmosphere of the emission chamber is divided up into a qualitative and a quantitative step.

Table 3 Edge conditions for first emission tests.

test parameters	sample conditioning	emission measurement
temperature	**23** °C ± 0,2 K	**23** °C ± 0,5 K
air humidity	50 % ± 5 %	50 % ± 5 %
surface specific ventilation rate	**1** $(m^2h)^{-1}$	**1** $(m^2h)^{-1}$
air velocity	0,1 **to** 0,3 m/s	0,1 **-** 0,3 m/s

3 Development of the toxicological method

This part of the project is handled by the Institute for Toxicology and Environmental Hygiene at the Technical University of Munich (ITU). In this respect, the toxic potential of building materials is estimated by means of literary data on the one hand, which is due to their chemical compositions and the emissions/immissions to be expected. On the other hand, the toxicity and eco-toxicity of building products is tried to be defined directly via their emissions/immissions by means of biological in-vitro testing systems. Another approach is the comparing toxicological evaluation of immission samples taken from typical houses (pre-fabricated houses, wooden houses, houses with gas heating, open fire-places and others).

Assessment of energy conservation measures suitable for retrofitting residential buildings in Kuwait

Authers : F. A. Al-Ragom, F.Al-Ghimlas.
Engineering Division, Kuwait Institute for Scientific Research, Kuwait, Kuwait.

Abstract
The code of practice for energy conservation in buildings was enforced by the Kuwaiti government through the Ministry of Electricity and Water in 1983. This implies that the most buildings built prior to the enforcement of the code lack the measures required to achieve efficient usage of energy. Significant energy saving potential may be realised from such buildings if suitable retrofitting schemes were implemented.
This paper addresses a number of energy saving retrofitting schemes, which are considered suitable for old residential buildings in Kuwait. The energy conservation measures considered for retrofitting were considered with the building envelope including the application of thermal insulation and use of energy efficient windows. For each scheme, a building model was developed and interrogated using the DOE2.1E energy simulation program.
The workability of the different schemes was investigated with some considerations given to the benefits and limitations related to installation techniques (such as interior vs. Exterior fitting of insulation material). Moreover, a cost benefit analysis for each scheme was also conducted in terms of energy utilization and cost requirements coupled with an optimization analysis to determine the best retrofitting scheme.
Keywords: Energy Conservation, Exterior Insulation and Finish System, Retrofitting.

1 Introduction

Retrofitting involves making considerable changes to existing buildings. These changes aim to rectify existing damage, improve building standards and increase or modify the capabilities of a building use. The range of energy saving measures involving retrofitting of residential buildings is significant. Energy saving improvements can be made to the building envelope, the building services and the appliances within the building. These range from those designed to improve the thermal efficiency of the building envelope to those which minimize internal heat gains and achieve better control of heating, ventilating air-conditioning facilities. Energy efficient design in building has progressed significantly in recent years, allowing for older building component to be retrofitted with respect to energy. Although residential retrofitting usually cannot be justified solely from an energy perspective, incorporating energy efficient principles into an existing retrofitting scheme can save future energy costs and alleviate wasteful consumption of energy. In this study retrofitting of residential buildings in Kuwait is being analyzed.

In Kuwait the Ministry of Electricity and Water (MEW) issued an energy conservation code in 1983. This code represents a set of regulations that guide the construction of new buildings. All houses that were authorized to be built prior to the code did not include any energy conservation measures such as using insulating materials and efficient glazing systems. A sample building which is used as a base case for the study analysis represents a house that lack the use of energy conservation measures as it is was authorized to be built before the implementation of the code. The case study house was built by the National Housing Authority (NHA), as a medium income family house.

2 Methodology

For the case study, a base case (case 0) was defined to represent a reference point. This base case represents the building as it was constructed. The building did not include any insulation materials for the wall and the roof sections. Moreover the windows were made of a single clear glass.

By the use of the DOE-2.lE building simulation program, in which the base case was entered, the building energy consumption and the peak load were determined. After that 14 different cases were constructed to represent different retrofitting cases and entered in the DOE-2.lE program to estimate their energy consumption and peak load electrical power details.

The different retrofitting cases are listed in table 1. Each case involves a different effect of adding an energy efficient system. Some effects are single effects such as adding wall insulation only, or roof insulation only or changing the glazing system alone. Other cases involve double or triple effects, they represent a combination of the single effects (ex. addition of wall and roof insulation at the same time), thus increasing the percentage of energy savings. Case 15 includes wall and roof insulation as well as double reflective glass. Thus it is the same as case 5, but the window area was reduced.

Case #	Description
0	Base case (no insulation), Infiltration = 1 .O single clear glass
1	Wall & roof Insulation, single clear glazing
2	Wall insulation only
3	Roof insulation only
4	Wall & roof insulation, Clear double glass
5	Wall &roof insulation, Reflective double glass

Table 1. Retrofitting cases description

3 Case study

The case study house is a two story building with an area of 27m x 19m. The living space area is $307m^2$. Walls and roof are not insulated. Windows are single glazed. For the retrofitting cases were insulation is used wall and roof insulation material was chosen to be extruded polystyrene as it is the most commonly used insulation material in Kuwaiti buildings [5].

4 Retrofit system installation

As it has been explained before, energy efficient retrofitting is concerned with improvements that can be made to the building envelope, the building services and the used appliances within the building.

In this study retrofitting measures that are related to the building envelope only were considered and they include adding wall, roof insulation and using an energy efficient glazing system.

From the theoretical point of view, buildings envelop energy efficient retrofitting can be obtained by applying several modifications to the wall, roof and glazing system. A combination of these modifications would lead to the optimum energy saving retrofitting case. But when it comes to implementation of the best retrofitting case other consideration will come into the picture, such as the fitting of the insulation materials.

Appropriate thermal insulant can be fixed on the external face of the building, internal surface of the wall of a room, or injected as foam, granules or fibres into any cavity within the wall. In Kuwait the wall structure does not include a cavity. Thus the fitting of thermal insulant, either on the room side of the inner leaf, or the weather-side of the outer leaf of the building are considered.

4.1 External insulation

It is the most suitable where the roof has a large overhang and the wall requires renovation and is composed of simple rectangular shapes with few fixings, such as pipes, which would have to be removed before the application of the insulant and refitted subsequently. Apart from the noise created during the fixing, there should be little disturbance to the occupants of the building during this retrofit operation.

Once the insulant is in place, the rate of heat loss is reduced and the fabric of the building acts as a better energy store, resulting in the occurrence of a more stable internal temperature. External cladding also reduces the temperature fluctuation (and hence mechanical stress generated) in the brick of the wall, and so less severe cracking is likely to ensue. Moreover, the external fitting of insulation would not affect the floor area. Unfortunately, the outer rendering, which protects the insulant from the vagaries of the weather, may also be susceptible to cracking so allowing rain, wind and atmospheric pollution to penetrate into the externally applied insulant, thereby reducing its effectiveness. [1].

4.2 Internal insulation

The installation of internal insulation occurs in some renovation projects, but it causes considerable disruption to the occupants of the building. Also, it normally requires additional differently skilled tradesmen to remove and/or resite the building services and ‘fixed’ furnishing (e.g. electricity sockets) mounted on, or sited near to, the affected walls. A further disadvantage is that the attachment of thermal insulant to the wall surfaces of room reduces the available floor area.

However, there are advantages in choosing to internally line the building with a thermal insulant. For instance, on multi-storey buildings is not required and the installation is not dependent upon good weather occurring, as would be needed for the application of insulation externally. Its presence is suited to the intermittent occupation of the building, because the room surfaces heat up quickly and are soon not ‘cold to the touch’. Also, most internal linings have significant sound-deadening qualities and can also provide excellent bases for surface finishes.

5 Building energy consumption analysis

From the results of the energy consumption data obtained by DOE-2.lE program and the analysis of the data table 2 was generated. By comparing the peak electrical load consumption to the base case, the optimum case was case 15 which involves the use of insulation for walls, roof and reflective double glass with reduced window area. The electrical load consumption was reduced by a value of 37.347 %.

The use of wall insulation only reduced the electrical load by 13 % while the use of roof insulation only reduced the electrical load by only 3 %. The effect of using a better glazing system reduced the electrical load by 7 % and 11 % for the double clear and double reflective glass respectively. By comparing cases 5 and 15 the window area reduction further dropped the electrical load by 6%.

Case No.	Peak Electrical KW	Peak Elec. Consumption W/m²	Annual Energy MWh	Annual Energy Consumption KWh/m²
0	36.70	119.529	148.958	485.2
1	29.85	97.225	108.302	352.8
2	31.89	103.863	119.575	389.5
3	35.55	115.814	137.43 1	447.7
4	27.13	88.382	99.460	324.0
5	25.15	81.917	86.059	280.3
6	34.21	111.423	139.866	455.6
7	32.61	106.222	126.744	412.8
8	26.76	87.152	97.339	317.1
9	29.55	96.254	115.181	375.2

15	22.99	74.889	73.18	238.4

Table 2. Total electrical requirements of the building

5.1 Peak load details

Figure 1 represents the peak load details of the building. It shows the breakdown of the total building cooling load when it reaches its maximum value (i.e. the peak cooling load). For case 15, which is the best energy efficient retrofitting case the main contributor to the building cooling load is the infiltration component (infiltration is the rate of uncontrolled air exchange through unintentional openings that occurs under given conditions), this component reduction would require use of weather strippers for windows and doors.

The heat gain by the different components of the building is shown in fig.1 shows the effect of using the wall insulation in different cases as compared to the base case. The wall gain dropped from 10.139 KW to 1.993 KW. And the effect of adding the roof insulation had dropped the roof gain from 4.238 KW to 0.82 KW. Further more, the use of a reflective double glass compared to the clear single in case 0 dropped the window gain from 6.235 KW to 4.024 KW. The reduction of window area decreased the window gain from 4.024 KW to 1.661 KW and increased the wall gain from 1.993 KW to 2.198 KW due to the increase of the wall area. The lowest annual electrical energy consumption was that of case 15.

5.2 Optimum energy consumption

The total annual energy consumption for the different cases is listed in table 2. The optimum case was case 15, as it’s annual energy consumption was found to be the

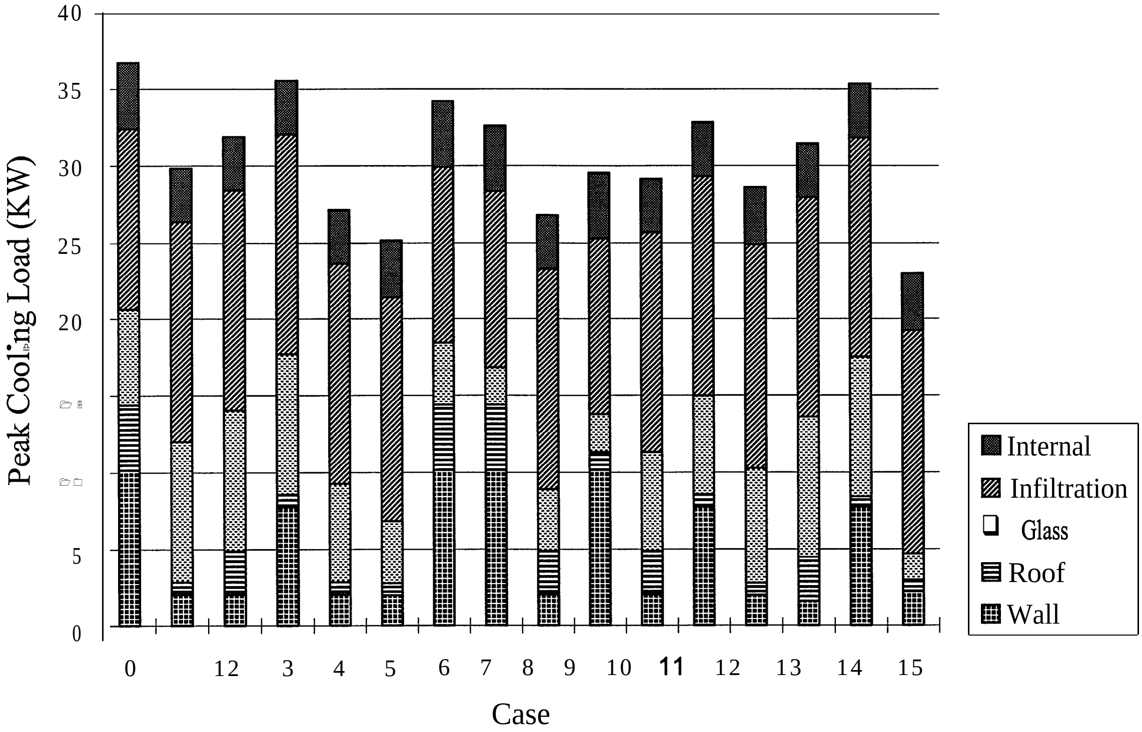

Fig. 1 Peak cooling load distribution for each case

minimum and of a value of 73.18 MWh compared to that of the base case which is 148.96MWh. Cases 13 and 14 were included to measure the single effect of increased R-value of wall and roof. Case 13 represented wall insulation only with R-l 5 resistance and case 14 represented roof insulation only with an R-20 resistance. Theses two cases were to be studied to provide an energy efficient retrofitting method if the building owner would like to change the wall exterior finish only or roof only. For case 13 the increased R-value further dropped the total annual electrical consumption by 1.6% in comparison to case 2 which represented the conventional recommended wall of R-l 0. For case 14 the increased R-value dropped the total annual electrical consumption by 0.76% in comparison to case 3 which represented the conventional recommended wall of R-1 5.

6 Cost benefit analysis

From the energy consumption analysis, the optimum case was case 15, the one that included all considered energy conservation measures with a reduced window area. Further analysis was carried out to determine the feasibility of the different retrofitting options. The customer investment for each retrofitting option was calculated. Particular assumptions were made in calculating the cost, as certain materials were used. For example, the new exterior finish of the building was assumed to be sand lime bricks.

The payback period for the customer was assumed to be 12 years, and the calculations were carried out accordingly. After 12 years the initial cost of retrofitting was not covered yet. The price of electricity for residential buildings is 2 fils/KWh (1 KD = 1000fils, 1 US$ = 0.306 KD), with that amount the payback period of the most expensive retrofitting options would be 51 years. As case study building was retrofitted thus the government will cover only the subsidised amount of electricity which is 32 fils/KWh. The payback period for the government will start from day one, as the government did not contribute to the initial cost of retrofitting and the electrical load for all the retrofitting cases was reduced. Table 3 shows the combined affect on the customer and the government, the national performance indices. Case 15, after 12 years shows the highest national performance index of 81.96 KD/m^2.

The number of residential buildings built prior to the application of energy saving code in Kuwait is over 42000. With that number, the total annual savings for the government for case 15 was found to be 100 million KD. For case 6 which was the case with the maximum annual consumption after the base case, total annual savings was found to be 12 million KD.

Case No.	Total Investment In Energy Conservation Measures	Annual Savings In Electric Energy Consumption	Total National Savings (12 years)	Normalized National Savings
	KD	KD	KD	KD/m^2
1	4107.0	1382.3	12480.65	4.5
2	1876.0	999.0	10112.26	3.3
3	2231.0	391.9	2472.02	1.3

15	5754.0	2576.4	25162.61	8.4

Table 3. Overall performance indices

7 Conclusions

The best retrofitting alternative should work along with the renovation of the building. If the owner of the building is considering changing the building outer cladding, the external fitting of the wall insulation is recommended. If the window glazing is considered it is recommended to use a wall resistance of R-10 supplied by the energy conservation code. If the glazing system is not changed then an increase in the thermal resistance of the wall is recommended. In internal fitting of insulation material it is a advised to use safe insulation such as the fibre glass, as in case of fire it will not produce toxic vapours.

The optimum energy conservation case was found to be the one with a triple effect in which the glazing system was changed to double reflective, wall, roof insulation materials were added and the window area was reduced. By the use of the conservation measures the percentage of electrical load reduction reached 37.5%. In comparison to single effects the electrical load reduction ranged from 3% to 13% for wall and roof insulation respectively.

This study presented different retrofitting options along with their energy consumption analysis and their cost effectiveness. In real situations each retrofitting project should be studied individually to take care of the project needs. Once the needs and requirements of each project are determined the most appropriate and cost effective system option or application method can be selected from those that are available.

It was found that the ventilation component of the building load was the major contributor to the building load, but it was not considered in this study. Thus any effort to reduce this component would have a great impact in reducing the total load. One way of reducing this part of the load is by decreasing the amount of uncontrolled air leakage by applying weather strippers to doors and windows.

The retrofitting cases payback periods for the customer were over 30 years, which is very long. Therefore, the building owner must be encouraged to retrofit his building by offering initial cost subsidisation and restricting the renovation loan acceptance with a condition that the building owner must retrofit his building with the most suitable option for his building.

Energy and IAQ assessment of the Swedish housing stock

Tommy Waller
Centre for Built Environment, Royal institute of Technology, Gävle, Sweden

Abstract

This paper presents assessments of energy efficiency and IAQ aspects of the Swedish housing stock based on sample survey data. The data consist of technical information about the housing stock, indoor climate measurements and information about the health of the residents. Also included in the database is a weighting system which makes it possible to estimate the characteristics of the housing stock and of any subgroups which are of interest to study.

To analyse these data, a computerized simulation model has been developed. The model can be used to assess the current state of the housing stock in terms of energy usage (space and water heating, ventilation, lights and appliances) and IAQ aspects. It can also be used to estimate the effects of and costs for measures to improve the housing stock with respect to energy efficiency and IAQ aspects.

The model contains a special function, kernel density estimation, by which plotted distributions of measured IAQ factors can be obtained. This function is used in the paper to assess the indoor air quality in the Swedish housing stock, by comparison of the distributions with prescribed norms and threshold limit values for measured indoor climate factors. A special study of ventilation is reported, where the consequences of increased ventilation, in terms of energy consumption and costs, are analysed.

Keywords: microanalytic simulation, density estimation, energy efficiency, indoor climate

1 Introduction

The paper describes two applications of a computer model for analysis of the Swedish housing stock with regard to energy efficiency and indoor climate.

The model is intended to be useful for studies of the balance between an efficient use of energy and a comfortable and healthy indoor climate, which is of vital importance for a sustainable development of the Swedish housing stock.

The first application is an assessment of the indoor air quality in the Swedish housing stock. The results indicate that an increase of the ventilation is required to safeguard a healthy indoor climate. The second application is a study of energy consequences of increased ventilation.

2 The ELIB survey

The ELIB survey, described in [1] and [2], was executed in 1992. This survey has a threefold purpose

(1) To obtain a technical description of the Swedish housing stock.
(2) To describe the indoor climate in the Swedish housing stock.
(3) To study potentials to save electricity in the Swedish housing stock.

Technical inspections and measurements of the indoor climate were performed in a sample of resedential buildings. Health symptoms and troubles were recorded by a postal questionnaire study.

When data for the buildings are analysed, the population is the Swedish housing stock, consisting of about 1.8 million buildings. When data from the postal questionnaire are analysed, the population is the 7.5 million residents of the Swedish housing stock. The original size of the building sample was 1200 and the number of investigated buildings was 1103, which means that non-response occurred in 8.1% of the ELIB sample of buildings.

3 The SIMBA model

The SIMBA model (Simulation Model for Building Analysis) has been developed for analysis of the Swedish housing stock with respect to energy efficiency, IAQ aspects and environmental impact.

The model is based on the principles of microanalytic simulation. This means that the model operates on the level of individual *microunits,* which for the SIMBA model are constituted by residential buildings. The properties of interest to study, for instance, energy use and indoor air quality in the housing stock, depends on technical characteristics, outdoor climate and habits of the residents of individual buildings. These dependencies are in the model expressed by mathematical and statistical relationships. In microsimulation modelling, such relationships are called *operating characteristics* of the microunits. A special heat balance model is contained in SIMBA for modelling of the operating characteristics that determine the energy consumption for heating a building. For a more detailed description of the model, see [3].

The data, required by the model, come from technical inspections of buildings and indoor climate measurements, performed in the ELIB sample survey. The model and its data can be considered as a miniature of the Swedish housing stock. This miniature can be scaled up to represent the whole housing stock, by a weighting system that is determined by the sampling design. This means that the model can answer questions such as:

What would be the total effects (in terms of energy consumption and costs) if the insulation is improved or if the ventilation is increased in all buildings in the Swedish housing stock ?

The uncertainty in the results, that depends on the randomness of the sample and random errors in data, can be determined statistically with variance estimation techniques.

4 IAQ assessment and description of energy use by density estimation

Measurements of indoor temperature [°C], ventilation air flow [m^3/h], relative air humidity [%] and radon gas concentration [Bq/m^3] were performed in each building of the ELIB sample survey. In addition, measurements of the concentration of volatile organic compounds (VOC) [µg/m^3] and formaldehyde [µg/m^3] were performed in a subsample of 100 single-family houses and 100 multi-family buildings.

Authorities which safeguard a good indoor climate in Swedish homes have prescribed requirements for a good indoor climate by the use of threshold limit values, norms and recommended levels for the IAQ factors. Such factors were measured in ELIB.

For some of these IAQ factors, ELIB provides for the first time ever, a possibility to assess the indoor air quality in the Swedish housing stock, by comparison of measurements from a nation-wide investigation with prescribed requirements.

Kernel density estimation is a method for estimation of probability distributions. This method provides an informative graphical tool for assessment of the indoor air quality, by diagrams in which values for prescribed indoor climate requirements are indicated in plots of estimated distributions for the measured IAQ factors.

A popular way to describe kernel density estimation is, that a 'bump' is placed on every observation and the estimated probability density function is obtained as the sum of the bumps. In the mathematical formula, the bumps are represented by a *kernel function* (K) and the formula for the kernel density estimator is given by:

$$\hat{f}(x) = (1/nh)\sum_{i=1}^{n} K[(x - X_i)/h]$$

where X_i are the measured observations, n is the number of observations and h is the 'bandwidth' or 'smoothing parameter'. Further details of this method are given in [4].

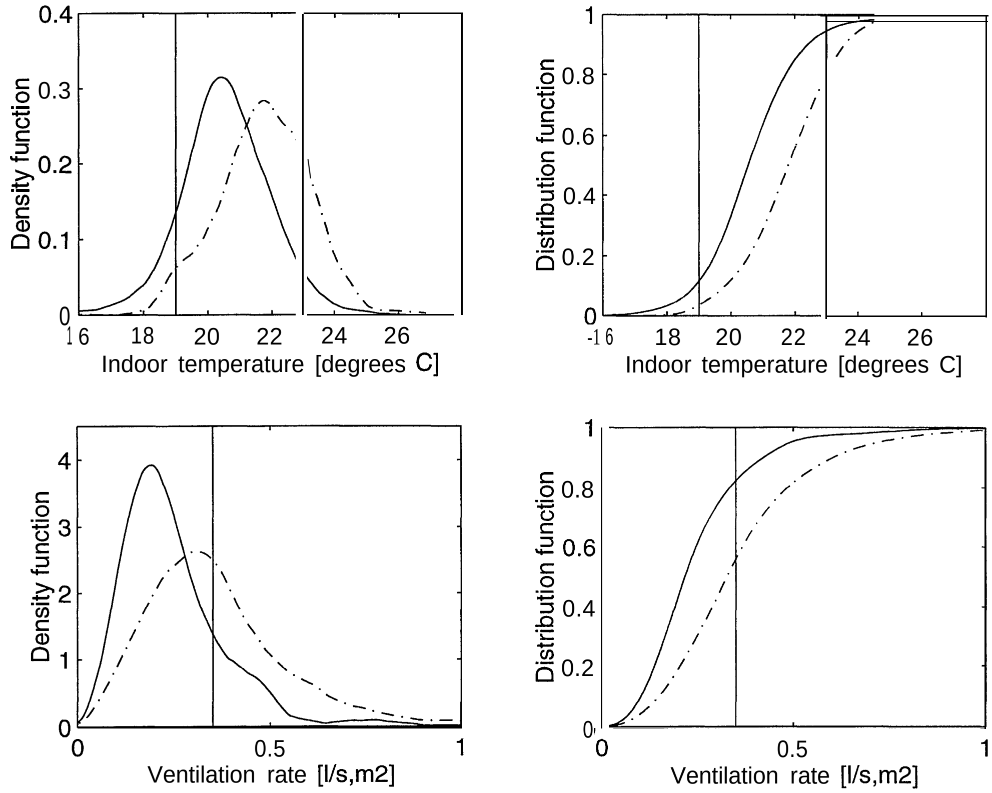
The given formula for the kernel density estimator is not directly applicable on data from a sample survey, where each observation has a weight (w_i) that reflects the relative importance of the observation. The SIMBA model contains a modified version of kernel density estimation, which is described in [5]. This density estimator is computed as:

$$\hat{f}(x) = (1/nh)\sum_{i=1}^{n} v_i K[(x - X_i)/h]$$

where v_i are equal to the survey weights (w_i) divided by their mean value $(\overline{w})$. By this standardization of the weights, the estimator will fulfil the requirement that its integral over the interval (-=, ∞) is equal to 1.

For the assessment of indoor air quality, estimated density functions are useful to show how the shape, location and spread of the distributions are related to prescribed recommendations, norms and threshold limit values. Estimates of the percentages of the Swedish housing that fulfil prescribed requirements, are more directly obtained from distribution functions than from density functions. Therefore, distribution functions are also estimated with the model, by numeric integration of estimated density functions. Some results of this application of the SIMBA model are presented in Figure 1 and Figure 2.

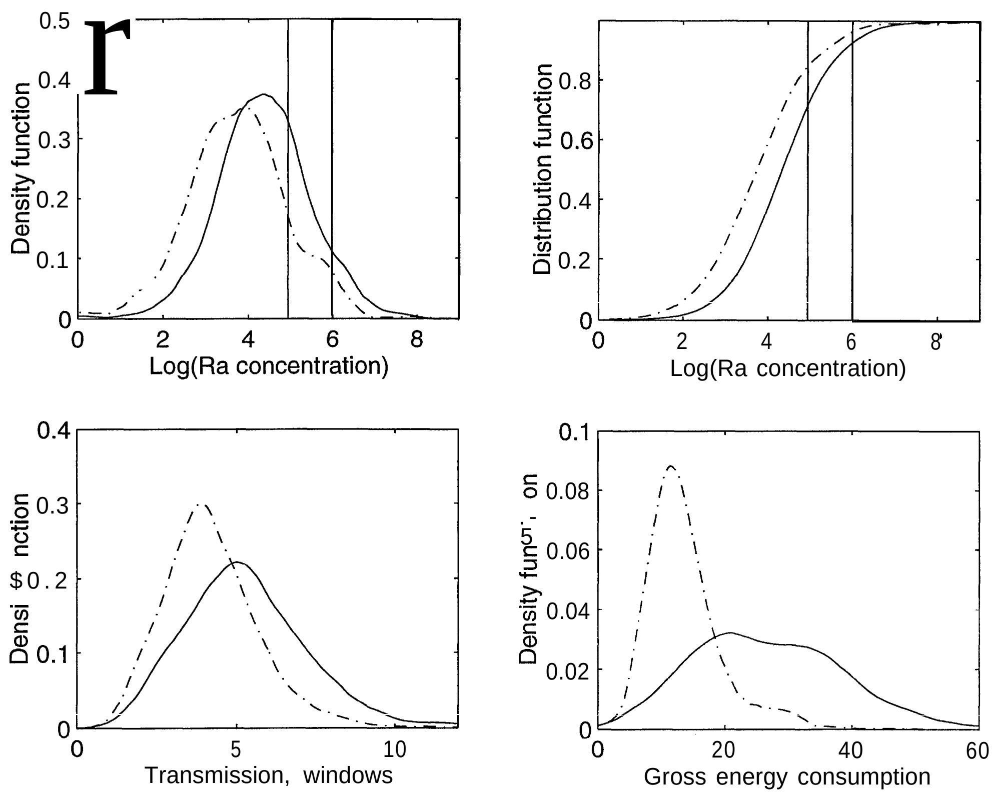
Figure 1. *Distributions of indoor temperature [° C] and ventilation rate [l/s,m^2] in single-family houses (solid curve) and multi-family buildings (dotted curve)*



The indoor temperature influences the energy consumption and is also important for the comfort of the residents. When the energy consumption is discussed, an indoor temperature of 20°C is often recommended. From comfort aspects, the 'directed operative temperature' is recommended to lie between 20°C and 24°C. The interval from 19°C to 23°C, indicated by vertical lines in the figure, is a compromise between these recommendations. According to the estimated density functions, a large proportion of the Swedish housing stock has an indoor temperature in this interval. Comfort problems from low temperature are most likely to occur in single-family houses. The estimated distribution function shows that about 10% have an indoor temperature below 19°C in single-family houses. Waste of energy due to unnecessary high temperature will mainly occur in multi-family buildings. About 20% of the apartments have an indoor temperature above 23°C.

For ventilation, there is a norm for new construction in Sweden. The ventilation rate should be at least 0.35 l/s,m^2 according to the norm. In the plotted distributions for ventilation, the norm value (0.35 l/s,m^2) is indicated by a vertical line. Estimated proportions, for which the ventilation norm is not fulfilled, are given by the intersections of the vertical line with the distribution function curves. These proportions are about 55% for multi-family buildings and over 80% for single-family houses. Thus, the ventilation is lower than the norm value in a substantial part of the Swedish housing stock, which is a rather surprising result.

Figure 2. *Distributions of radon gas concentration in natural log of [Bq/m^3] units, transmission through windows [MWh/apartment, year] and gross energy consumption [MWh/apartment, year]*



The upper part of Figure 2 shows estimated density and distribution functions for radon gas concentration. From a consideration of the risk for lung cancer, certain threshold limit values have been prescribed for the radon gas concentration in Swedish buildings. These values, which are 400 Bq/m^3 for older buildings and 140 Bq/m^3 for new construction, are indicated by vertical lines in the figure. Measures to decrease the radon concentration are most urgent in buildings where the concentration exceeds 400 Bq/m^3. An estimate of the number of apartments with a radon concentration above this threshold limit value, will have uncertainties due to errors in the radon measurements and in the estimation metod. A study of these uncertainties, performed in the ELIB survey [1], indicates that 90 000 - 200 000 apartments in the Swedish housing stock have a radon concentration above 400 Bq/m^3.

The lower part of Figure 2 gives examples of how density estimation can be used to describe the energy consumption for heating the Swedish housing stock, and to analyse effects of measures to decrease this energy consumption.

The left plot shows distributions of transmission losses through windows in single-family houses, before (solid curve) and after (dotted curve) upgrading to windows with three panes, in all single-family houses where the windows have one or two panes.

The right plot shows distributions of the gross energy consumption for single-family houses (solid curve) and multi-family buildings (dotted curve). The cuves show that the variation and average value of the energy consumption are substantially higher in single-family houses than among apartments in multi-family buildings.

5 Energy consequences of increased ventilation

Present research has shown that the problem of health risks associated with the indoor environment is very complex, and therefore technical solutions alone can probably not solve the whole problem. However, there is fairly large agreement that moisture in buildings and insufficient ventilation are factors that contribute to increased health risks, and these factors can be affected by technical means. As the assessment of the indoor air quality (performed in section 4) indicates that the ventilation is insufficient in the Swedish housing stock, it is interesting to study the concequences of increased ventilation.

This section reviews some results of a study addressing this topic [6]. The study was made for the Swedish Governmental Commission on Environmental Health [7].

In addition to the ventilation norm of 0.35 l/s,m^2 discussed above, alternative ventilation requirements have been considered, such as 0.70 l/s,m^2 and 0.15 l/s,m^2 + 10 l/s,person.

To analyse effects on the energy consumption of increased ventilation, the SIMBA model was used to estimate total annual ventilation heat losses in the Swedish housing stock. The above alternatives are included in the study, which gives the following computation cases:

- Standard norm: increased ventilation to 0.35 l/s,m^2 in all buildings
- High alternative: increased ventilation to 0.70 l/s,m^2 in all buildings
- Mixed alternative: increased ventilation to 0.35 l/s,m^2 + 10 l/s,person in all buildings

Computation results, broken down by building type and heating system, are given in the following table.

Table *1. Total ventilation heat losses in the Swedish housing stock [TWh/year]*

Type of building and heating system	Current ventilation	Standard norm fulfilled	High alternative fulfilled	Mixed alternative fulfilled
Single-family:				
Direct electricity	1.6	2.6	4.9	2.6
Heat pump	*0.4*	0.7	1.4	0.7
Individual plant	4.7	7.6	14.6	7.4
Block central	0.5	0.5	0.9	0.7
District heating	0.5	0.8	1.5	0.8
Other way	0.2	0.2	0.5	0.3
Multi-family:				
Direct electricity	0.1	0.2	0.3	0.2
Heat pump	0.2	0.3	0.5	0.3
Individual plant	0.7	0.8	1.4	O.S
Block central	0.8	1.0	1.8	1.1
District heating	7.3	8 0	13.2	*8 7*
Single-family	7.8	125	23’.8	12.5
Multi-family	9 2	10.2	17.1	11.1
All buildings	13.0	22’.7	40’.9	*23’.6*

Table 1 shows that the estimated increases of the energy consumption in the Swedish housing stock, that would be caused by increasing the ventilation are:

Standard norm	22.7 – 17.0	=	5.7 TWh/year
High alternative	40.9 – 17.0	=	23.9 TWh/year
Mixed alternative	23.6 – 17.0	=	6.6 TWh/year

The possibilities of heat recovery are not considered in these estimates of the increased energy consumption. A separate computation for ventilation systems with heat recovery, indicates that the standard ventilation norm can be fulfilled without any increased energy consumption, and for the high alternative, the energy consumption would be increased by about 10 TWh/year, if ventilation systems provided with heat recovery are installed.

To achieve the considered improvements of the ventilation in the Swedish housing stock, new ventilation systems must be installed in buildings where the ventilation requirements are not fulfilled.

The investment costs for this improvement of the Swedish housing stock are considerable. For new ventilation systems with heat recovery, these costs were estimated as 62 GSEK for the standard norm, 119 GSEK for the high alternative and 67 GSEK for the mixed alternative.

6 Health and comfort aspects of increased ventilation

The following positive health and comfort effects can be obtained by increased ventilation in the Swedish housing stock:

- Moisture in the buildings would descrease, which means that the health risks from mites and mould will also decrease.

- Unhealthy pollutions (e.g. radon gas, carbondioxide and volatile organic compounds) would descrease.

- The problems from stuffy air and unpleasant odour would descrease.

There may also be negative health and comfort effects of increased ventilation, such as troubles from noise, draught, dry air and dust. These troubles would become frequent, if the ventilation is increased to a high level.

An analysis of how the troubles of the residents from dry air depend on the ventilation has been performed in the ELIB survey [6]. The results indicate that only small troubles would likely occur for a ventilation level of 0.35 $l/s,m^2$. Troubles from noise, draught and dust are also likely to be small for this ventilation level. A conclusion from this discussion is that the positive effects will be much more important than the negative effects, if the ventilation is increased to the norm level 0.35 $l/s,m^2$.

7 Discussion

The paper gives examples of the usefulness of statistical modelling and simulation techniques in research concerned with properties of the Swedish housing stock, such as energy efficiency and indoor climate.

To assess the indoor air quality, density estimation is used to present data from indoor climate measurements, by easily comprehensible graphs of estimated probability distributions.

This assessment, accentuates a need to increase the ventilation in the Swedish housing stock.

Energy consequences of increased ventilation are analysed, by microsimulation techniques, for three alternative ventilation requirements.

An interesting result of the analysis is, that the ventilation can be increased to 0.35 $l/s,m^2$ in all buildings, without any increased energy consumption, if ventilation systems provided with heat recovery are installed. However, there is a considerable investment cost for this improvement of the Swedish housing stock (estimated as 62 GSEK). To make it possible to realize the improvement, efforts must be made to develop new cost effective ventilation solutions.

Cost efficiency and financial feasibility of retrofitting with heat insulation of existing residential buildings in İstanbul

N. Şahal, E. Özkan
fstaxibul Technical University, Faculty of Architecture, Istanbul, Turkey

Abstract

Istanbul is a metropolis with twelve million inhabitants. Nearly all the existing residential buildings in Istanbul have not sufficient heat insulation, yet, affordable retrofitting a residential building with sufficient thermal insulation is in question for the households. A research project was set to develop applicable energy efficient and economic retrofitting systems for the external envelopes of the existing residential buildings in Istanbul. In the research, DOE-2 computer program was used to analyze and to evaluate the thermal performance of the buildings. The two groups of data files, the weather data file of İstanbul and the building description input file representing the existing residential buildings and the energy efficient alternative insulation and fenestration systems were prepared for the simulation. The total heat losses and savings before and after retrofitting of these buildings were calculated. Finally the economic efficiency of alternative retrofitting systems were evaluated.

In this study, a sample building is considered where the yearly energy loss is 205.43 MWh and the required energy for heating is 293.47 MWh. The referred retrofitting systems with 5 or 15 cm external heat insulation and clear or low-e double-glazing provides 145.83 MWh (49.7 %) and 181.4 MWh (61.8 %) energy savings.

The pay-back periods for the investments are 18 to 25 years for the clear and the low-e double glazing systems, 4-7 years for the insulation systems with single glazing, and 9-11 years for the insulation systems with low-e double-glazing. The present worth of the monetary equalance of the energy savings for a period of 5 years with an interest rate of 5% meet only a certain part of the initial investment for the retrofitting. The present worth of the remaining cost of the retrofitting is the amount may be paid by the present worth of household savings according to the income groups as the following:

- The lowest income households with 5% savings can pay the remaining part of the investments made for the insulation systems without double-glazing in 5 years.
- The households in the lower and the middle income groups with their 10% and 5% savings respectively can pay the required amount for the insulation systems with the alternative double glazing systems.

Therefore, the households have to be encouraged for saving, and also the costs of retrofitting systems have to be reduced by developing the cost efficient techniques in order to afford an applicable energy efficient systems for retrofitting existing buildings.

Key Words: existing residential buildings, financial feasibility, heat insulation, household savings, income distribution, insulation cost, life-cycle costing, retrofitting

1 Introduction

Istanbul is a metropolis with twelve million inhabitants. The external envelopes of most of the residential buildings were observed to be thermally uninsulated and those which were insulated unable to exceed the values determined in the national and international standards and specifications for energy conservation. Yet, affordable retrofitting a residential building with sufficient thermal insulation is in question for the households.

A research project was set to develop applicable energy efficient and economic retrofitting systems for walls, floors and roofs for the rehabilitation of external envelopes of the existing residential buildings and the squatter housing in Istanbul. The thermal performance of the existing buildings and developed alternative energy efficient retrofitting systems were evaluated. The total heat losses and savings before and after retrofitting of these buildings were calculated. Finally the economic efficiency of alternative retrofitting systems were evaluated with Life-Cycle Costing [1).

1.1 Existing residential buildings in İstanbul

A survey was carried out at certain districts in Istanbul where registered and squatter housing schemes were exist, to understand the existing situation of such buildings. Thus, series of data concerning the surrounding environment of the typical buildings; characteristics of buildings as size, number of storey, total floor area, structure, heating system; opaque and transparent components of the building, and external envelope as pitched and flat roofs, walls, windows and floors open to external environment, and the building thermal characteristics were prepared.

1.2 Computer program for the simulation

A PC version of DOE-2.1E computer program developed for the energy analysis simulation, has been used to analyze the thermal performance of the residential buildings, [2]. This program employs weighting factor method, an hourly thermal load calculation is performed based on a physical description of the building and that hourly ambient weather conditions including solar radiation. The two groups of data files, the weather data file of Istanbul and the building description input file representing the existing residential buildings in Istanbul and the energy efficient alternative insulation and fenestration systems were prepared for the simulation, [3].

1.3 Weather data and building data required for the simulation

Hourly weather data file, Test Meteorological Year-(TMY) file, containing one year of data for each weather variables, required for the simulation with DOE-2, was prepared for Istanbul. The weather variables available in the TMY files are solar time and local standard time, extraterrestrial, direct-normal and observed radiations, dry-bulb and dew-point temperatures, atmospheric pressure, wind speed and direction, sky cover and snow cover. For preparing Istanbul weather file, the measured hourly weather data were either used directly or calculated as the dew point temperature, the extraterrestrial radiation and the direct-normal radiation, [4]. The TMY weather file of Istanbul was packed in (ASCII) formats and processed with the computer program, [3].

Data for the description of each building, 'Building Description Language-(BDL) file' are required to run the DOE-2 program. The data include the location and orientation of the building; the space conditions of the building as temperature, humidity, infiltration rate, floor weight; the physical characteristics prepared according to the existing buildings; the materials used for the construction; and the transient effects of shading. Finally, the buildings data are systematically prepared according to the typified residential buildings that include settlement type, floor area, number of storey and the physical characteristics of the existing buildings in general.

2 A typical residential building and heat insulation systems for retrofitting

In this study, a five storey block of flats-(K2A) representing one of the typical existing residential buildings in Istanbul was selected as a sample building. This building is composed with reinforced concrete structure, non-load bearing external brick wall, 1.50 m. wide overhanging floors open to external enviroment, the single pane windows, four balconies in three facades of the building and the tiled pitched-roof reflects the typical properties of building stock in Istanbul.' The non-load bearing external walls of the building rendered externally and plastered internally is formed from hallow bricks with 13.5 cm thickness. The normal floor, the total floor, the total exterior wall and the total window areas are 230, 1066, 5 18 and 232 m^2 respectively. The transparency ratio for all facades is % 35 and the building width/depth ratio is 0.7.

Internal and external heat insulation systems applied with dry and wet construction were found adaptable in retrofitting the opaque components of the exterior envelope of the existing residential buildings in Istanbul. For the transparent components, single-glasses in windows and doors were replaced with clear double-glazing or double glazing with low-emissivity coating-(Low-E) applied on outer glass. Materials considered for thermal insulation were selected from among cellular polymers as extruded and beaded expanded polystyrene and mineral fiber insulators as glass or rock-wool fiber panels with thermal conductivity design value-(k) of 0.035 or 0.04 W/mK.

3 Energy losses and savings for the retrofitted sample building

The applicable heat insulation and fenestration systems determined for the retrofitting the external envelope of the sample building-(K2A) and heat loss through the building and the energy consumed for heating are given in Table 1. The clear single-glasses in windows are replaced with clear or low-e double glazing. The inner and outer surfaces of the external walls, overhanging floors, and the roof slab are thermally insulated with 3, 5, 8, 10 and 15 cm thick expanded beaded polystyrene.

The sample building was simulated with DOE-2.1E program and the energy losses are calculated for the sample building retrofitted with alternative insulation systems. The yearly energy loss is 205.43 MWh and the required energy for heating is 293.47 MWh for the existing sample building. The energy losses and the consumed energy for the alternative retrofitting systems of the sample building is given in Table1.

Retrofitting the roof slab with 3 cm. expanded beaded polystyrene (R3G1) is the least energy efficient retrofitting system which provides 18.28 MWh (6.2 %) energy saving yearly. Replacing single-pane glass with clear double-glazing conserves 44.15 MWh (15.1 %) energy. The referred retrofitting system-(DR5G2) with 5 cm external heat insulation and clear double-glazing provides 145.83 MWh (49.7 %) energy saving.

Retrofit Systems	HI, mm W	R	F	GU	YHL MWh	YECH MWh	Retrofit System	HI, mm W	R	F	GU	YHL MWh	YECH MWh

Table 1: The externally-(D) and internally-(I) applied heat insulation-(HI) systems for wall-(W), floor-(F) and roof-(R), glazing systems-(Gl, G2, G3), the total heat losses-(YHL) and the energy consumed for heating-(YECH) in a year, before and after retrofitting the building K2A. Thermal transmittance design value for glazing-(GU)

The insulated system-(DR15G3), where the external surface of the external walls, the exterior overhanging floors and the roof slab are thermally insulated with 15 cm. expanded beaded polystyrene and the single pane windows are replaced with low-e double-glazing, provides the maximum yearly energy conservation as 181.4 MWh (61.8%) energy savings. Therefore this system is considered to be the most energy efficient retrofitting system that applicable to the sample building, however, it may not be cost efficient for the user and/or for the country.

4 Life-cycle costs of retrofitting systems and paying the initial investment back

The per square meter costs of each insulation and glazing systems for energy efficient retrofitting are calculated with fixed prices and the systems having the lowest costs, highest energy savings are determined for retrofitting. The value of energy conservation and the yearly monetary savings due to the energy conservation is calculated for each retrofitting system with life-cycle costing model.

The minimum pay-back periods-(N) of the insulation with glazing systems are calculated for comparison. The aim is to look for the period in which the initial investments are met with the monetary equivalence of energy savings. The formula is:

$$N: \log [A / (A-P*I)] / \log (1+I)$$

Where, N: pay-back period, A: monetary equalance of annual energy savings
P: the initial capital invested for retrofitting, I: interest rate, considered 5%.

The pay-back periods for each insulation system with glazing for the sample building K2A are shown in Figure 1. In the building, the roof insulation-(RG1) has the least, 2 to 3 years, and the double glazing, 18 to 25 years, has the highest pay-back periods. The pay-back periods increase for the insulation systems with single glazing-(IRG1, IG1, DRG1, DG1) from 4-7 years to 9-11 years for the systems with double-glazing-(IRG3, DRG3, IRG2 and DRG2). The energy efficient retrofitting system with 50 mm thick insulation and double glazing-(DR5G2) has the pay-back period of 10 years.

Five years period is generally considered appropriate for the pay-back of the thermal retrofitting of existing buildings. Therefore, this study was carried out to answer the question "can the households afford the initial investment of an applicable energy efficient retrofitting system with both the energy savings provided by the retrofitting system and the savings from their household incomes during a period of 5 years?"

As it is seen in Figure 1, the most cost efficient heat insulation thickness for each retrofitting system is between 5 to 8 cm. Therefore, 5 cm. heat insulation and 5 years pay-back period are considered fixed parameters for the study.

4.1 Income distribution and household savings

Inequality of income distribution among the individuals is an economical fact of life. In the cities, the income groups share of the gross national product of Turkey is as follows:

	Normal	Cumulative
Lowest income group (first 20%)	4.8 %	4.8 %
Lower income groups (second 20%)	8.2 %	13.0 %
Middle income groups	11.9 %	24.9 %
High income groups	17.9 %	42.8 %
Highest income groups (last 20%)	57.2 %	100 %

The "Gini Rate" which is high as 0.51 shows the level of inequality.

Even though many households living in cities borrow money from family relatives, banks, etc., the principal source of any investment for financing remains that of the savings acquired by the households. The general findings show that the lowest income group consumes all their income or do not save any amount while the lower income and the middle income group may save 5 to 15 %, [5]. This is also the case for Turkey. A study carried out at Pınar, an old squatter housing district in Istanbul, showed that the households save to improve their housing. See Figure 2 for the saving tendency of the household in Pınar district, [6]. However, they will not spend all their savings for the retrofitting of their houses.

4.2 Paying the initial investments back

The present worth of the monetary equalance of the energy savings-(P_{es}) for a period of 5 years with an interest rate of 5% will meet a certain part of the initial investment-(P_{ic}) for the retrofitting. In these conditions, the present worth of the savings is P_{es}:A×4,329

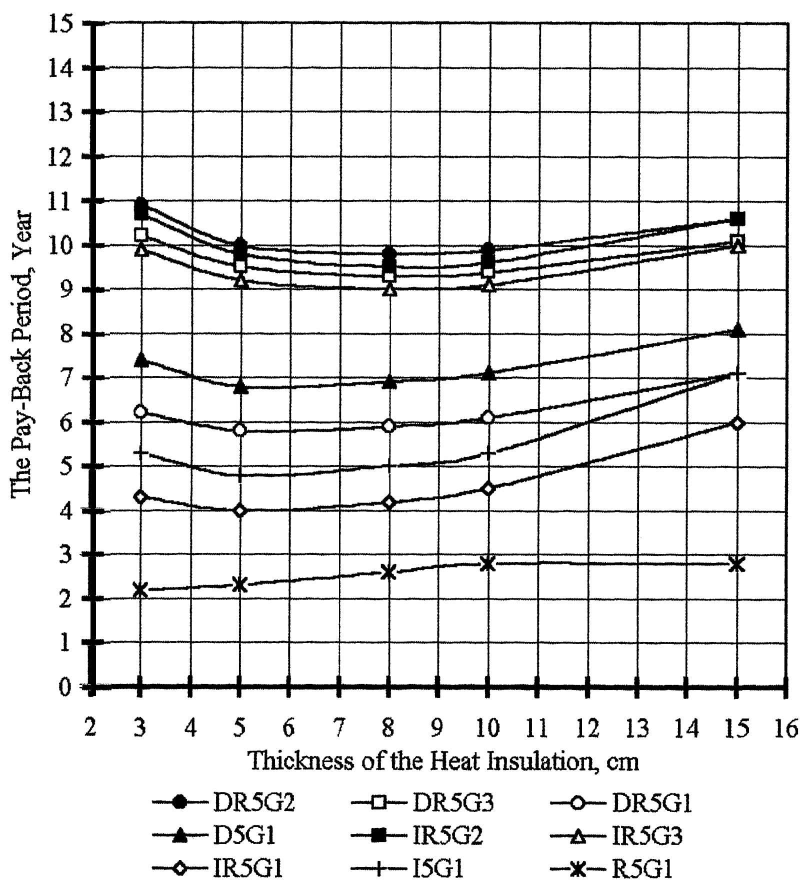

Figure 1: The pay-back periods of alternative retrofitting systems of the sample building K2A. The pay-back periods of the clear and low-e double-glazing-(G2, G3) are 25 and 18 years.

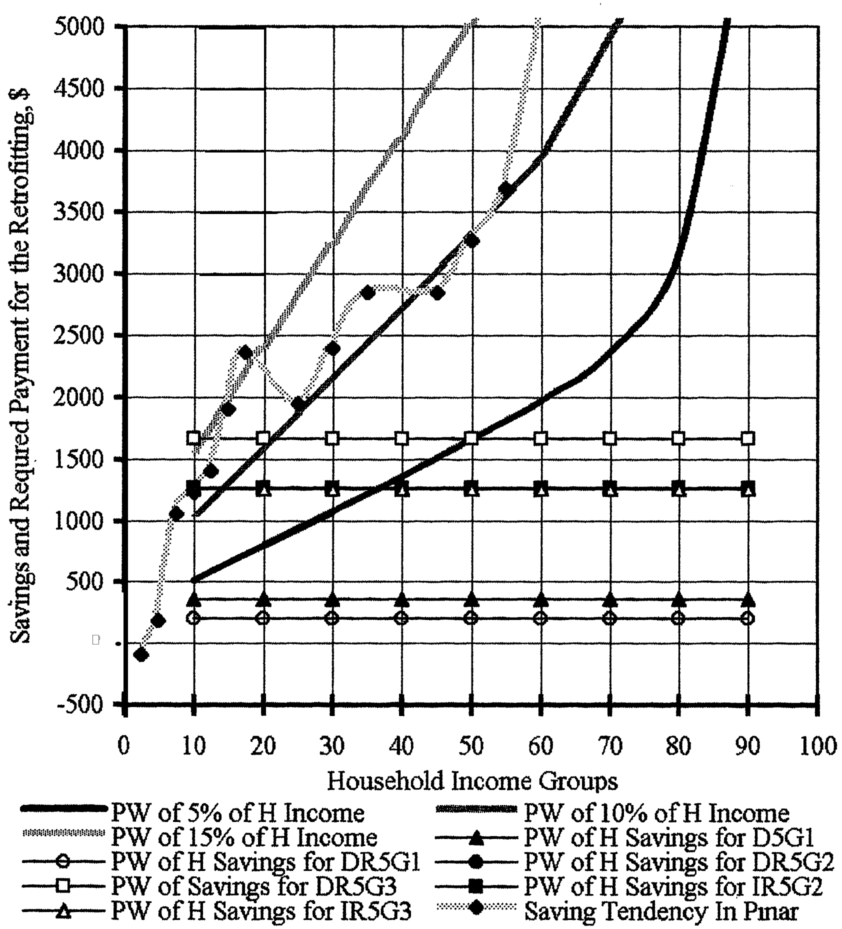

Figure 2: The present worth-(PW) of 5, 10 and 15 % of households' income-(HI) for the period of 5 years, the savings tendency in Pinar disrict and the required payment for the alternative retrofitting systems

where "A" is the cost of yearly energy savings, [7]. Hence, the present worth of the remaining cost of the retrofitting-(P_{ic}-P_{es}) is the amount may be paid by the present worth of 5 to 15% the household income-(P_{lhs}) for a period of 5 years. The yearly monetary savings due to the energy conservation is calculated for each retrofitting system Table 2. It shows that retrofitting with 5 cm insulation without new glazing-(DR5G1) is the most cost effective as it requires minimum amount of household savings to pay the remaining $2018 in 5 years. Among the alternatives, retrofitting system with low-e double-glazing-(DR5G3) is the least cost effective but most energy efficient system as it can be acquired with the maximum household savings of $17158 for the sample building.

Retrofit Systems	YHL MWh	YECH. MWh	YES MWh	MEC $\Year	PWE $\5Years	P_{ic} $	P_{lhs} $
Existing	205.43	293.48	6.00				
D5G1	148.91	212.72	so.75	2 753	11917	15 504	3 586
DR5G1	133.94	191.34	102.14	3482	15 073	17 091	2 018
DR5G2	103.35	147.64	145.84	4 972	21 523	38·179	16 656
DR5G3	103.58	147.97	145.50	4 960	21473	38632	17 158
IR5G2	124.66	178.09	115.39	3 934	17 029	29655	12 626
IR5G3	114.53	163.61	129.86	4 427	19 165	31747	12 582

Table 2: The present worth of energy savings-(EWE) for a 5 years with an interest rate of 5%, the initial investments of each retrofitting systems-(P_{ic}) and the present worth of the loan that is to be paid by the household savings-(P_{lhs}) for the sample building; yearly energy savings-(YES), monetary equivalence of the energy savings-(MEC).

The yearly disposable household incomes are calculated for each income groups by considering the Gross National Product [6]. The present value of 5 to 20% of household incomes are calculated as the present value savings with an interest rate 3 % of all income groups in order to put forward the household savings that can pay the amount of loan required for each retrofitting systems, Table 3.

Income Groups	YDII	YDHI	YDHI as %, $				PW of DHI for 5 Years, $			
	$	$	5	10	15	20	% 5	% 10	% 15	% 20
Lowest income groups	695	3473	174	347	521	695	795	1 591	2 386	3 182

High income groups	2 591	12953	648	1295	1943	2591	2 966	5932	8 898	11865
Highest income groups	8 278	41390	2 070	4 139	6 209	8 278	9478	18 957	28 435	37 913

Table 3: The yearly income of individuals-(YDII) and households-(YDHI), 5' to 20 % of household incomes-(YDHI), and the present worth-(PW') of 5 to 20 % of a household income-(DHI) for a period of 5 years with an interest rate of 3%.

The present worth of 5 to 15% of the household incomes for a period of 5 years and the present worth of the retrofitting system costs that remained after the present worth of the monetary equivalence of the energy savings is deducted from the initial investment are displayed in Figure 2. The all households with 5% savings can pay the remained amount of investments made for the insulation systems with the double-glazing, except the lowest income groups.

Natural night ventilation and thermal inertia

0. Douzane, J-M. Roucoult and T. Langlet
Laboratoire de Thermique du Batiment - IUT Genie Civil
Universite de Picardie Jules Verne, Amiens, France

Abstract

The objective of this study is to propose a simplified characterization of the thermal inertia, as part of the implantation of a system of summer refreshment by night cooling ventilation. On the low of a previous study, realized with the help of the modal analysis, the interactions between the thermal inertia of a building and the night cooling ventilation are clarified. Then, it is shown that the notion of useful thermal mass is here maladjusted to take into account the thermal inertia of the building and that it would suit to substitute it an approached calculation of the main time-constant of the building.

More, the necessity to add a parameter characterizing the rapid dynamics of the air temperature of a zone is justified. Finally, a characterization of the thermal inertia based on the three criteria calculation is proposed. An approached value of the time-constant during the period of night cooling and out of this period and an approached value of the height of the line associated to the rapid dynamics.

Keywords: time-constant, night cooling ventilation, pilot study, rapid dynamics, summer refreshment, thermal inertia.

1 Introduction

Taking into account the thermal inertia during the conception of a building remains a delicate problem. In fact, the thermal inertia is not accessible directly ; alone its consequences are observable. Its effects can be very different according to the nature of the outdoor thermal solicitations to which the system is submitted and the position of observation of the response that we have choseen [1, 2].

However, at the beginning of a project, the designer has to use simplified criteria so as to direct its study. The useful thermal mass or an approached value of the main time-constant are generally used to anticipate effects of the thermal inertia. But, these global criteria do not take into account the nature of thermal solicitations and appear often insufficient [3].

In previous works [4, 5], we have proposed a simplified characterization, of the thermal inertia of a one-zone building, that can be used in the pilot project and takes into account the nature of thermal solicitations. The aim of this paper is to apply these works to the natural night cooling ventilation of buildings.

2 The summer refreshment by night cooling ventilation

This process of refreshment, consists in increase the air exchange rate during the unoccupied period of night in order to eliminate the heat that was stored in the building mass during the day. Blondeau and al [6] have shown that some sites are more favourable to the implantation of a night cooling ventilation. Indeed, a raised value of the difference of the average temperature between the day and the night gives a best efficiency to this technique. These same authors have proven also that the night ventilation will give best result if the building has relatively important solar protections. An experiment directed by Sperandio and al [7] has shown that the good distribution of the fresh air in the building increases the global efficiency of the system ; this technique will be therefore more efficient for the small volumes.

In order to avoid discomforts in the beginning of the occupied period, this technique requires adapted scenarios of regulation. More, the utilization of an air conditioning in complement of this system is generally not desirable, because the air conditioner modifies the past thermal behaviour of the building therefore annihilates a susceptible gain part to be realized by the night ventilation.

It is obvious that potentialities of a night cooling ventilation are closely linked to the thermal inertia of the building, but we often forget that the increased air exchange rate modifies characteristics of the initial thermal system and therefore its thermal inertia. In a previous study [8], we have analyzed the role of the air exchange rate on the dynamics of the temperature of a zone.

In the following paragraph, we will use results of this study, in as part of the implantation of a night cooling ventilation. We will release some necessary parameters in order to take into account the thermal inertia of a building in pilot study.

3 The air exchange rate and the thermal inertia

3.1 The thermal inertia of a system

The thermal behaviour of a system in dynamic state is completely defined by the totality of these eigenvalues and corresponding eigenmnctions that are these intrinsic characteristics. They have elsewhere allowed to give the first definition of the thermal inertia [9]. Eigenvalues set the time scale of all dynamic phenomena to which the thermal system is submitted. The form and the amplitude of the eigenfunctions allow to analyze the action of each mode on the different components of the system.

Natural modes, that are in infinite number, can be classified summarily in rapid modes and in slow modes. Among these, some are dominant and others weaks. In fact, alone some modes sufficed to reconstitute correctly the dynamic state. The slow dynamic is usually dominated by several modes of large time-constants ; the first one is generally the most influential. This first mode translates in fact the importance of the coupling by the air of walls delimiting the zone. The study of natural modes shows also that there exists always a dominant rapid mode associated to the time-constant τ_r around of which we will be able to amalgamate the rapid dynamics. This mode will be all the more rapid that the coupling air - walls will be strong.

We show that the notion of useful thermal mass, that characterizes in fact only the low dynamic, is here maladjusted to take into account the thermal inertia of a building in the case of the installation of a night cooling ventilation

3.2 Action of the air exchange rate on time-constants

We have shown in [8] that when the air exchange rate increases, all natural times corresponding to the natural modes decrease and have as limit a ***local*** value of a wall of the system. Especially the ***global*** first time-constant tends to the largest time-constant of walls.

As an example, the table 1 gives the twelve first time-constants of a cell for air exhange rates of 1, 5 and 10 volumes per hour. The cell has a volume of 200 m^3 insulated by the interior with 2 cm of insulator. The external wall has a surface of 150 m^2 and the cell contains 60 m^2 internal walls of 8 cm of concrete.

Mode number	**Air exchange rate (volume per hour)**		
	1	**5**	**10**
1	53.61	32.85	25.01
2	6.38	6.36	6.35
3	0.801	0.783	0.769
4	0.562	0.562	0.562

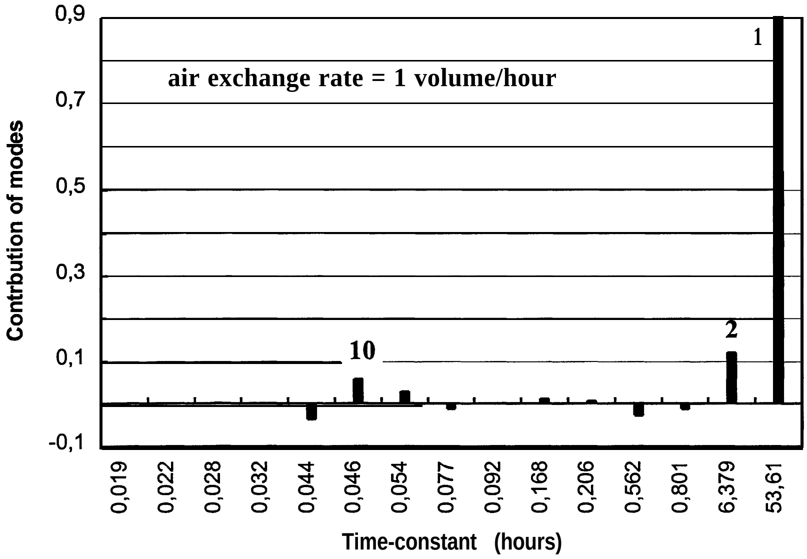
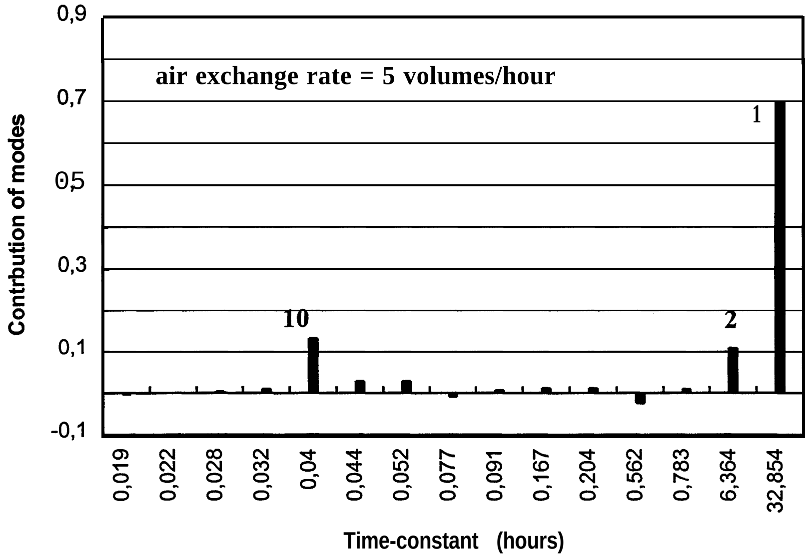
approached τ_1	49.87	24.68	15.13

Table 1: Evolution of the time-constants (hours) as a function of the air exchange rates

In fact, for higher air exchange rates, the low dynamic will be marked by a disorderly time evolution of the walls. Indeed, the air do not insures its role of coupling between walls. These latters will be therefore thermically dissociated. The notion of useful thermal mass, that supposes implicitly a good coupling air - walls, appears in this case maladjusted to translate modifications of the thermal inertia as a function of the air exchange rate. Van der Mass and al [10] had already noticed it on experimental tests realized on a building of the Leso in Lausanne.

An approached calculation of the time-constant of the dominant slow mode, integrating variations of the air exchange rate, would allow a best taken into account of this phenomenon as it is shown in the last line of the table 1. It would suit here to undertake this calculation during the period of night ventilation and out of this period.





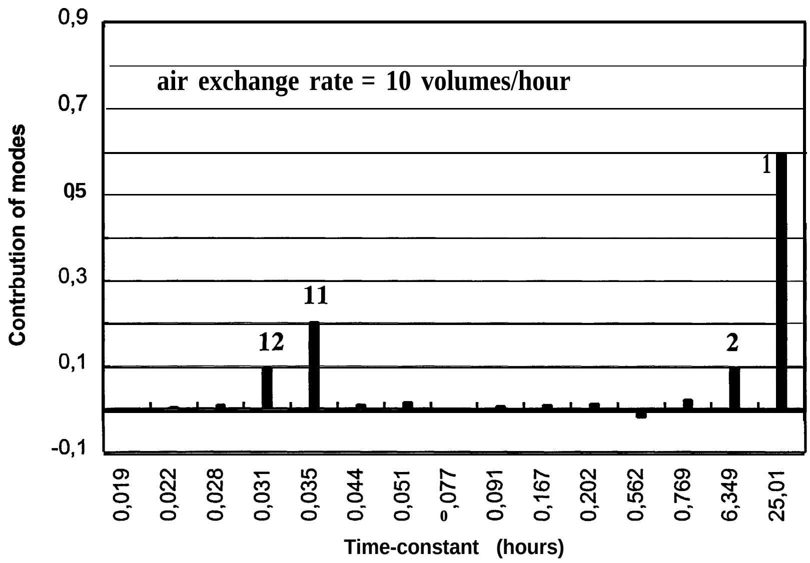


Figure 1: Response spectrums of the indoor air temperature of a cell, with interior insulation, as a function of the air exchange rate

3.3 Action of the air exchange rate on the temperature response of a zone

During the implantation of a night cooling ventilation, it is important to understand the air temperature response of a zone under the action of the outdoor temperature solicitation.

At this end, the figure 1 represents the spectrums of the air temperature response of a zone for different air exchange rates. We can notice that the importance of the first mode is less and less pronounced when the air exchange rate increases contrary to the dominant rapid mode τ_r (see § 3.1) that have an action more important on the air temperature response of the zone. For a rate of 1 volume per hour, the rapid response represents 4 % of the rise to the steady state, on the other hand it happens to 35 % for a rate of 10 volumes per hour.

In period of night ventilation, the rapid dynamic represents an important part of the air temperature response of a zone. It proves therefore necessary to attach to the characterization of the thermal inertia a parameter that takes into account the rapid response of the temperature of zone in period of night ventilation.

4 Simplified criteria taken into account the thermal inertia

According to the conclusions of the previous paragraph, we propose to characterize the thermal inertia by the three following parameters :

τ approached value of the time-constant characterizing the low dynamic during the occupied period of no-ventilation.

τ_s approached value of the time-constant characterizing the low dynamic during the unoccupied period of night ventilation.

r the part share taken by the rapid dynamic in the air temperature response of the zone during the unoccupied period of night ventilation.

4.1 Calculation of approached time-constants

This calculation can be carried out by using a property of temperature fields demonstrated by Sicart [9]. When a temperature field has the form of a natural mode, the ratio of the energy contained in the system by the outgoing flow is equal to the time-constant associated to this mode. This property allows an approached calculation of the time-constant of the dominant mode that has a close form to the one of the steady state associated to the convective power solicitation of heating. The methodology of this calculation is detailed in [1, 4].

4.2 Calculation of the parameter r

We can use as indicatory r an approached value of the height of the line (i.e the contribution of the natural mode), associated to the rapid dynamics, of the spectrum of the air temperature response of a zone to an outdoor temperature solicitation [4].

This criterion r can be calculated by noticing that the part taken by the rapid dynamics in the air temperature response of a zone can be approached by the ratio of the heat flow brought to the air by the flow exchanged with walls at the outdoor air temperature.

$$r = \frac{Ca.Qr}{Ca.Qr + Kv.Sv + \sum_k hi_k A_k}$$

with

Ca the calorific capacity of the air (Wh / m^3°C)

Qr the air exchange rate (m^3/h)

Kv the the heat transmission coefficient of glazings (W/m^2°C)

Sv the surface of glazings (m^2)

hi_k the superficial exchange coefficient of the wall (k) (W/m^2°C)

A_k the surface of the wall (k) (m^2)

The thermal resistance of the interior insulating is integrated in the coefficient hi_k.

For the example quoted in the paragraph 3.2, τ = 49.9 h, τ_s = 15.1 h and r = 0.365

5 Conclusion

We have shown, in this paper that the notion of useful thermal mass is insufficient to take into account the thermal inertia, in pilot study, in the case of the presence of a night cooling ventilation. It would suit to substitute it the approached calculation of the dominant time-constant of the low dynamic that while remaining simple, presents the advantage to integrate dynamic characteristic variations of the thermal system during the variation of the air exchange rate.

More, it is indispensable to add there a parameter characterizing the rapid dynamics during the period of night ventilation, what can be made simply by an evaluation of the height of the line associated to the dominant rapid mode.

Finally, to be really usable, this method will have to be linked to weather report conditions of the site and to the solar protections rate.

Solar thermal storage with phase change materials in domestic buildings

K. C. W. Ip
Department of Construction, Geography & Surveying, University of Brighton, UK

Abstract
This paper summarises the investigation and analysis of a solar space heating system incorporating phase change materials for use in domestic buildings in the UK. Encapsulated phase change material modules designed to absorbed heat from water pipes are used for the thermal storage of solar energy. By choosing a suitable phase change material to take advantage of the latent heat absorbed during phase change of the material from solid form to liquid form, a large quantity of daytime solar energy can be stored and used for space heating at a later time. Conventional roof mounted flat plate solar panels have been selected for solar collection and the thermal energy is transferred to the phase change material through a series of pipes under the floor.

A dynamic modular simulation program is used to study the performance of the proposed space heating system. Components which simulate the two-dimensional heat transfer and the phase change process are established. Seven system configurations are analysed and their performances and energy savings are evaluated.

Results indicate the performance of the proposed system is affected by the attainment of phase change temperature in the phase change material. The generation of this phase change temperature is related to the area and efficiency of the solar panel, the temperature gradient along the length of pipe and the heat transfer characteristics of the equipment. The proposed system, which uses commonly available commercial materials and equipment, demonstrated to be viable. The results show the thermal effectiveness of phase change material and significant amount of energy saving can be achieved.

Keywords: Thermal storage, phase change materials, solar space heating, computer simulation

1 Introduction

Latent heat is the large quantity of energy which needs to be absorbed or released when a material changes phase from solid state to liquid state or vice versa. The magnitude of the energy involved can be demonstrated by comparing the sensible heat capacity of concrete with the latent heat capacity of a phase change material, calcium chloride for instance. Concrete has a sensible heat capacity of approximately 1.0 kJ/kgK [1] whereas calcium chlorine can store/release 190 kJ/kg [2] of energy during its phase change transition. It is obvious that any energy storage systems incorporating phase change materials will comprise significantly smaller volumes when compared to alternative materials storing only sensible heat.

One of the potential applications of phase change materials is the storage of solar energy. This is particularly suitable for dwellings where the roof can be used to collect the solar energy during the day, which is then used at a later time. As solar energy is a renewable energy source, reliance on fossil fuels and the greenhouse gas emissions can thus be reduced.

It is difficult to assess the performance of solar energy storage by phase change materials due to the dynamic nature of the system and the large number of variables involved. The main objectives of this study is therefore twofold. Firstly, to demonstrate the use of a computer simulation tool for the study of solar thermal storage systems incorporating phase change materials. Secondly, to use the simulation tool for investigating the performance of a proposed system. The following sections introduce the basic concepts of modular simulation, the functions of the modular components and the construction of the computer simulation models. The computer models of different configurations of the proposed system are simulated, the results are analysed and conclusions are summarised.

2 Simulation program

The simulation program used in this study is a dynamic modular simulation program [3]. The modular concept is to represent each component of a system as one module such that they can be linked together to form a complete network and subsequently the behaviour of the system can be studied. Each component is "self-contained" in the sense that information can only be conveyed through connecting nodes, the components react according to the information received and subsequently write new information to the nodes.

3 The components

Solution algorithms are contained within the component for describing its process. The component reads information from its nodes, parameters and internal states. The outputs are sent to the nodes and internal states.

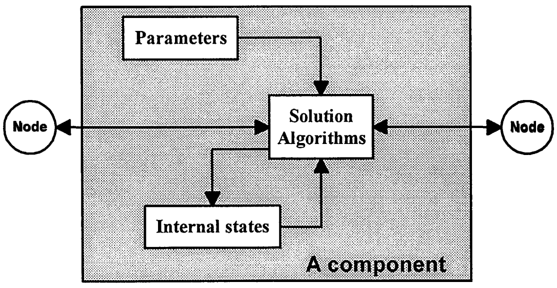

Figure 1 A component

Figure 1 shows the conceptual configuration of a component.

3.1 Pipe with phase change material

This is formed by two concentric pipes (see figure 5b) with the phase change material sandwiched between the two pipes. This component computes: 1) the radial heat transfer between the fluid, the phase change material and the ambient; 2) the heat transfer due to latent heat at phase change temperature; 3) the axial heat transfer along the length of the pipe and; 4) the water flow generation due to pressure difference exerted at its two ends. The descriptions and algorithms for these four functions are as follows:

1) Radial heat transfer

The pipe with phase change material calculates the radial heat transfer from the water inside the pipe to the surrounding air by the lump parameter procedure [3]. Figure 2 is the circuit representing the one dimensional radial heat flow of a section of the pipe. The governing radial heat transfer equations for a section j of the phase change material pipe are [4]:

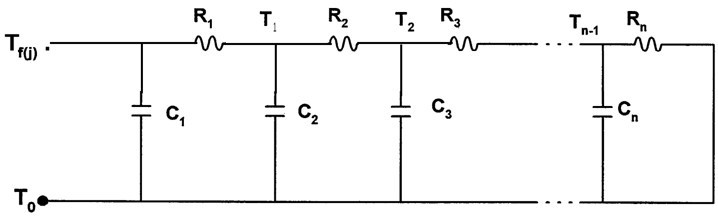

Figure 2 Radial heat flow network

$$m_f C_f (T_{f(j)} - T_{f(j-1)}) = C_1 \frac{dT_{f(j)}}{dt} + \frac{T_{f(j)} - T_1}{dt}$$

$$\frac{T_{f(j)} - T_1}{R_1} - \frac{T_1 - T_2}{R_2} = C_2 \frac{dT_1}{dt}$$

$$\frac{T_{(i-2)} - T_{(i-1)}}{R_{(i-1)}} - \frac{T_{(i-1)} - T_i}{R_i} = C_i \frac{dT_{(i-1)}}{dt}$$

$$\frac{T_{(n-2)} - T_{(n-1)}}{R_{(n-1)}} - \frac{T_{(n-1)} - T_o}{R_n} = C_n \frac{dT_{(n-1)}}{dt}$$

m_f = mass flow rate of fluid [kg s^{-1}]
$R_1 = R_{si} + 0.5\, R_{met}$ [K W^{-1}]
$R_2 = 0.5(R_{met} + R_{pcm})$ [K W^{-1}]
$R_{3\ to\ n-1}$ = thermal resistance of phase change material [K W^{-1}]
$R_n = R_{so} + 0.5R_{met}$ [K W^{-1}]
$C_1 = M_f C_f$ [J K^{-1}]
$C_2 = M_{met} C_{met}$ [J K^{-1}]
$C_{3\ to\ n}$ = thermal capacity of phase change material [J K^{-1}]
T = temperature [K]
M = mass [kg]
C = specific heat capacity [J kg-' K^{-1}]
f, met, pcm = subscript for fluid, metal, phase change material
0, si, so = subscript for outside, inside surface, outside surface. All surface heat transfer coefficients are taken from the CIBSE guide [5].

2) Phase change heat transfer

When phase change occurs the latent heat effect is significantly greater than the sensible heat, hence the radial temperature distribution within each thin layer of the phase change material is assumed to be uniform [6]. This temperature uniformity is further maintained by subdividing the phase change material into thinner layers as shown in figure 2.

At phase change temperature $T_{phç}$ the heat energy is used for the phase change process. When the time step is small:

If $Q_{lhtmax} > Q_{lht} > 0$

$T_{pcm} = T_{phc}$

$Q_{lht} = \int W_{pcm}\, dt$

Q_{lht} = latent heat content of the phase change material [J kg^{-1}]
Q_{lhtmax} = maximum latent heat capacity of the phase change material [J kg^{-1}]
T_{pcm} = temperature of the phase change material [K]
W_{pcm} = rate of heat flow to the phase change material [Wkg^{-1}]

3) Axial heat transfer

To take into account the axial temperature gradient that exists in a long pipe and the narrow temperature range of the phase change process, each pipe component is subdivided into a number of sections along its length. The number of sections in each pipe is 16 but it can be increased by emulating a single pipe with several smaller pipes connected in series.

4) Water flow generation

The D'Arcy equation, which includes the static pressure generated by vertical pipes, is used:

$$Rm^2 = |(P_1 - P_2)+P_h|$$

P_1, P_2 = pressure at either ends of the pipe [Pa]
R = flow resistance of the pipe [Pa s^2 kg-“]
P_h = static pressure [Pa]
m = mass flow rate of fluid [kgs^{-1}]

3.2 Solar panel

The basic equation for the solar heat Q collected from unit area of the solar panel is [7]:

$$Q=F^*[I(t^*a)-U(T_i-T_a)]$$

F = collector heat removal factor
t*a = product of transmittance and absorptance
U = the upward heat loss coefficient [$Wm^{-2}K^{-1}$]
T_i, T_a = water inlet temperature and atmospheric air temperature [K]
I = total solar irradiance [Wm^{-2}]

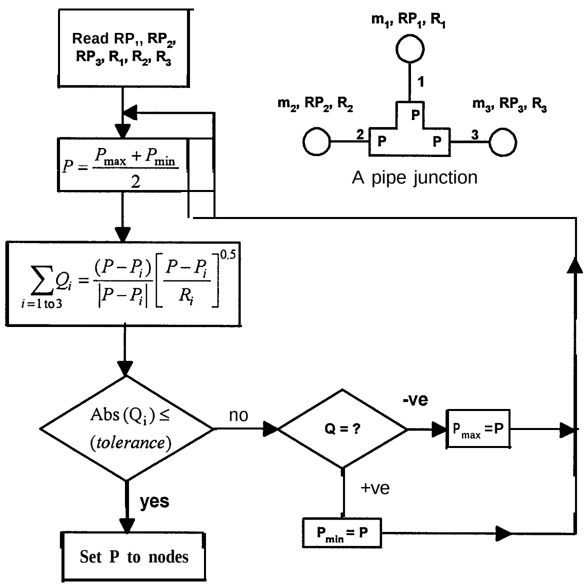

Figure 3 Flow chart for solving pressure at pipe iunctions

3.3 Pipe junction

The pipe junction reads the mass flow rates m_i, remote pressures RP_i and pipe resistances R_i sent to it by the pipes on its branches and adjusts its own pressure in such a way that the sum of the mass flow will be zero. This new pressure P is found by a bi-sectional iterative method [3]. The flow chart in figure 3 shows the principle to achieve the solution.

3.4 Pump and fan

The pump or fan provides motive force for fluid, generates a pressure which drives flow through the attached components. The pressure developed by a pump or fan is a function of the flow it is called upon to deliver and is related to its characteristics. The equations governing the pump/fan component are:

$$P_1 - P_2 = (am^2 + bm + c)$$
$$P_3 - P_1 = R_1 m^2$$
$$P_2 - P_4 = R_2 m^2$$

P_1 to P_4 = total pressure [Pa]
m = mass flow rate of water [kg s^{-1}]
a, b, c = constants

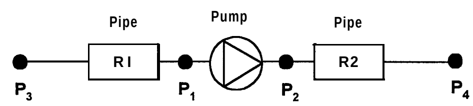

Figure 4 Pump with connecting pipes

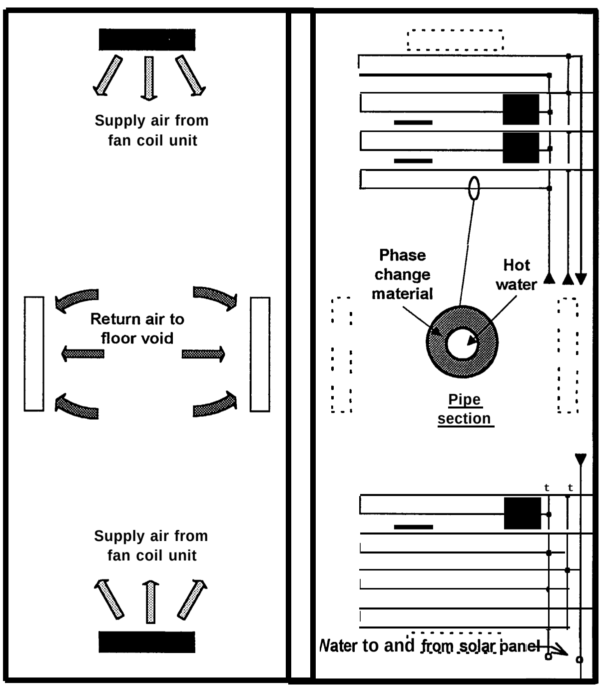
Table 1 Properties of phase change

3.5 Weather

The solar radiation data are based on the CIBSE guide section A2 [8] basic direct solar irradiances for southern England between October and March. The dry bulb temperatures are simulated using the factors given in the same section.

4 The model

The proposed building used in the simulation model is a typical two bedroom bungalow of 7m x 10m x 2.4m high. The sitting/dining room, which is to be heated by phase change material, has a measure of 3m x 7m. Solar panels of a total area of 20m^2 are installed on the south facing pitched roof. The phase change material is placed inside the house under the floor of the sitting/dining room. The phase



(a) (b)

Figure 5 Plans of room layout and phase change material under the floor void change material is contained within the pipe walls of two concentric copper pipes (see figure 5b). A pump in the loft circulates water between the solar panel and the pipes containing the phase change material. Two floor-standing fan coil units located at opposite sides of the room provide space heating for this room. Dampers are used to control air supply to the fan coil units. Air is drawn from the floor void below the units as long as the air temperature in the floor void is above the room air temperature. Otherwise air is drawn from the room through the front faces of the units. Any deficiency in heating requirement is complemented by the heating coils inside the fan coil units. Figure 5a illustrates the layout of the fan coil units and return air grilles. Figure 5b shows the layout of water pipes containing phase change material in the floor void and an exploded view of a pipe section.

5 Simulation

Flow networks similar to figure 6 are constructed using the components created in section 3. As preliminary studies indicated the importance of water temperature within the circuit, the investigation therefore focuses on the solar panel configuration and the length of the pipe containing the phase change material. Seven cases listed in table 2 are simulated to compare their performances. As effect of the latent heat is much greater than the sensible heat, only latter is considered in the simulation.

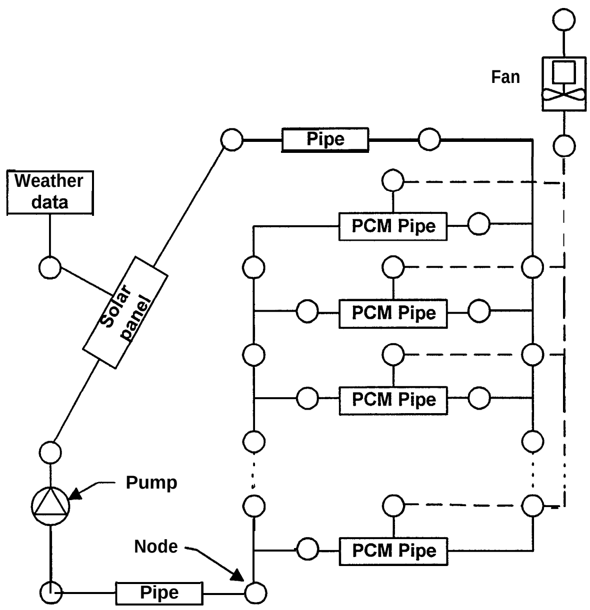


Figure 6 Computer simulation model

The space heating load of the building is separately analysed using the National House Energy Rating (NHER) program [9]. The single glazed solar panels used in the models have a total area of 20 m^2, with a heat removal factor of 0.93, heat loss coefficient of 7.0 W/m^2K and the product of transmittance and absorptance of 0.8. There are four parallel phase change material pipes linked to each solar panel. The phase change material used in this study is calcium chloride ($CaCl_2.6H_2O$) and its properties are shown in table 1 [2].

Case	Solar panel	PCM pipe	Total length (m)	Total volume of phase change material (m^3)
1.	5 m^2 x 4 nos.	3m x 16 nos.	48	0.09
2.	5 m^2 x 4 nos.	6m x 16nos.	96	0.18
3.	5 m^2 x 4 nos.	9m x 16 nos.	144	0.27
4.	5 m^2 x 4 nos.	12m x 16 nos.	192	0.36
5.	10 m^2 x 2 nos.	6m x 8 nos.	48	0.09
6.	10 m^2 x 2 nos.	9m x 8 nos.	72	0.14
7.	10 m^2 x 2 nos.	12m x 8 nos.	96	0.18

Table 2 Case studies

6 Results and discussion

The result from the NHER Program indicates the model room has a space heating load of 13.3 MJ when it is heated for eight hours with average outdoor and indoor temperatures of 21°C and 10°C respectively. The simulated total solar radiation reaching the solar panel on the pitched roof over 24 hour periods for the design days of the six months for SE England, as shown in figure 7, indicates that the available solar energy is well above that required for space heating. However under 2% of the total solar energy is converted into latent heat in the seven case studies.

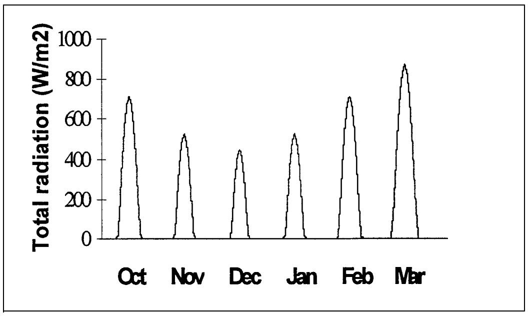

Figure 7 Total radiation on the solar panel

Based on the space heating load established from the NHER program, approximately 70 kg of phase change material is sufficient to provide the space heating requirement by latent heat alone. The amount of phase change material can be used in practice is restricted by the space of the floor void and the area of solar panel that can be mounted on the pitched roof.

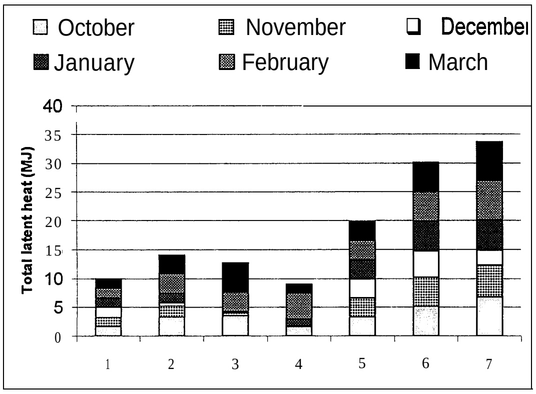

Figure 8 Latent heat captured

Figure 8 shows the amount of latent heat being captured in each of the seven cases (table 1) under investigation. Results indicated that for the same amount of solar radiation, the main factors affecting the efficiency of theses storage systems are water temperature, heat transfer between the pipe walls and phase change process within the material itself. The amount of latent heat stored can vary significantly even when the same amount of phase change material is used in the systems as indicated by case 2 and 7. The use of the larger size solar panel in cases 5 to 7, which results in higher flow temperature, is more favourable for the latent heat storage. Lower water flow rates in return for higher water temperatures could have been used but this would change the heat transfer coefficients and affect the comparisons in the case studies. When evaluating performance per unit length of pipe, it appears that 3 m pipe has the highest latent heat content for cases 1 to 4 and the 6m pipe for cases 5 to 7. Based on the calculated space heating load and excluding the pump and energy, the savings due to solar thermal storage with phase change material are between 18 to 32% (figure 10).

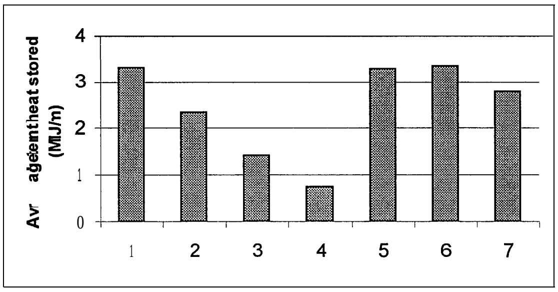

Figure 9 Latent heat stored per unit length

7 Conclusion

Due to the dynamic nature of the solar radiation, the two-dimensional heat transfer and the phase change process, the study of thermal systems involving phase change materials and solar energy is a complex and tedious task. This paper illustrates how such kind of analysis can be performed by means of a modular simulation program.

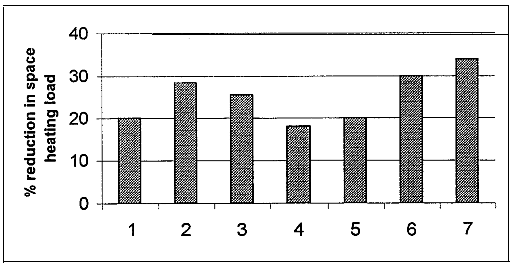

Figure 10 Energy reduction

This study demonstrates not only the viability of incorporating phase change material in domestic buildings to reduce the space heating energy consumption, it also shows that such a system can be constructed using commonly available materials and equipment. Results indicate the performance is affected by the attainment of phase change temperature through heat transfer from the water contained in the pipe to the phase change material. The generation of this phase change temperature is related to the area and efficiency of the solar panel, the temperature gradient along the length of pipe and the heat transfer efficiencies of the equipment. This study has laid the groundwork for further research on the use of phase change material in buildings. As domestic space heating accounts for a large proportion of the energy use in the UK, the exploitation of solar energy in conjunction with the storage potential of phase change material is a design option ought to be explored.

Moisture performance of retrofitted exterior walls of multi storey residential buildings in İstanbul

M. C. Altun
Istanbul Technical University, Faculty of Architecture, Istanbul, Turkey

Abstract

Most of the residential buildings in Istanbul need retrofitting to improve energy efficiency and indoor comfort. The placement of a thermal insulation layer either inside or outside of the wall are common retrofitting systems for the opaque component of the exterior wall. The moisture performance of those offered retrofitting systems, interacting with the existing typical wall construction of the Turkish building industry are widely unknown yet. There are also no moisture control guidelines available for retrofitting practice in istanbul.
The aim of this study is the prediction of the effects of water vapor diffusion on moisture performance of retrofitted typical wall constructions. In the study, retrofitting systems, placements of the thermal insulation layer, types of the insulation materials, their thickness and types of finishing materials are utilized as variables. The indoor climatic conditions are considered to be constant, but indoor relative humidity is altered for each case. Meteorological data for Istanbul is taken as the outdoor climatic conditions.
The moisture performance is determined with a computer simulation program using a transient, one dimensional, finite difference model for heat and moisture transfer.
In the paper the moisture distribution, expressed in relative humidity (RH), within the existing wall construction retrofitted either inside or outside with a mineral fiber or cellular plastic thermal insulation for the end of the month February is graphically presented.
When the indoor mean relative humidity is less than 60% and the indoor temperature is 21°C, the moisture content within all studied retrofitted typical wall constructions of residential buildings in Istanbul is in an "allowable" range. If indoor relative humidity exceeds 70%, excessive accumulation of moisture occurs on the inner surface or within the retrofitted wall construction.
Keywords: Exterior wall, moisture performance, residential building, retrofitting, water vapor diffusion.

1. Introduction

In Istanbul nearly all residential buildings, built in the seventies and eighties are mainly five or six floors high and have a reinforced concrete skeleton structure. The opaque component of the exterior wall mostly consists of 13.5 cm thick hollow bricks with rendering on both sides and the windows have a wooden frame with single-glazing. During the winter period the insufficient heat resistance of the external envelope causes either insufficient indoor conditions from the point of view of thermal comfort or excessive energy consumption for heating to achieve thermal comfort. since the mid nineties there is an effort, encouraged by the municipality of Istanbul, to retrofit existing buildings to achieve energy saving, reduction of air pollutants and CO_2 emission. The placement of a thermal insulation either inside or outside of the existing wall is a recommended retrofitting practice. When improving the thermal performance of the wall by adding a thermal insulation layer, the moisture performance of the wall under the new conditions should also be taken into consideration.

As water vapor diffusion trough the opaque component of external walls of buildings nearly always occurs due to water vapor partial pressure differences between the interior and exterior environment this is the main kind of moisture transfer under normal conditions. The different layers resist the moisture transfer due to their different material properties i.e., resistance factors. Moisture is accumulated in front of layers with high resistance factors or extraordinary amount of moisture is captured in the wall due to design or construction failures. As moisture is affecting the physical performance of walls, it can cause important defects. Excessive moisture accumulation in the wall construction decreases the heat resistance of materials and so the indoors thermal comfort is affected. Moisture accumulation on the inner surface of walls causes water stains, peeling paint and mold growth. Mold growth in turn has effects on air quality and user’s health.

The purpose of this paper is to predict the effects of water vapor diffusion on moisture performance of retrofitted typical wall construction using meteorological data for Istanbul and to develop a moisture control guideline using results from those predictions.

2. Calculation method

In the calculation method, for appraising the effects of water vapor diffusion on the thermal and moisture performance of external walls, the hourly and daily fluctuations of outdoor climatic elements, i.e. temperature, relative humidity (RH) and solar radiation as well as the interaction between moisture content and material properties, i.e. thermal conductivity and vapor diffusion resistance factor were considered, [1]. The main features of the calculation method, are as follows :

- A finite difference method.
- Both moisture and temperature distribution; they are calculated transiently.
- The calculations are one - dimensional.
- Transport of moisture is mainly by vapor diffusion, but in the case of when relative humidity exceeds 100% i.e. the moisture content reaches the critical value at any point, moisture transport is by capillary suction due to water absorption properties of the materials.

- Material properties vary with the moisture content.
- Convection transfer of heat and moisture are considered at the boundaries.

Under transient conditions with no internal generation the one-dimensional heat diffusion equation is;

$$\frac{\partial T}{\partial t} = a \cdot \frac{\partial^2 T}{\partial x^2} \qquad (1)$$

For solving equation (2) with the finite difference method, the wall is assumed to be divided into "m" Ax - layers. the temperature ($T_j^{t+\Delta t}$) at any internal node "j" representing a Ax - layer and the surface temperature ($T_1^{t+\Delta t}$) at the new time "t+Δt" are determined with equation (2) and (3) respectively.

$$T_j^{t+\Delta t} = a \cdot \frac{\Delta t}{\Delta x^2} \quad [illegible] \quad 1 - \frac{2 \cdot a \cdot \Delta t}{\Delta x^2}) \cdot T_j \qquad (2)$$

$$T_1^{t+\Delta t} = \frac{2 \cdot \alpha_o \cdot \Delta t}{\gamma \cdot c \cdot \Delta x} \cdot (T_e - T_1) + 2 \cdot a \cdot \frac{\Delta t}{\Delta x^2} \cdot (T_2 - T_1) + T_1 \qquad (3)$$

where,

a	: [m²/s]	Thermal diffusivity
α_o	:[W/m²°C]	Convection heat transfer coefficient, outside
γ	: [kg/m³]	Density
c	:[j/kg °C]	Specific heat
T_e	:[°C]	Sol -air Temperature

The moisture distribution in the wall is determined as offered in [2]. Under the assumption that during the time interval "At" the conditions (T, φ, P) at any Ax -layer and the environment are constant the quasi - steady state moisture mass flux due to water vapor partial pressure differences is:

$$m = \delta \cdot \frac{\Delta P \cdot \Delta t}{\mu(\varphi) \, . \, \Delta x} \qquad (4)$$

where,

m	: [kg/m²]	Moisture flux
δ	: [kg/mhPa]	Water vapor permeability
AP	:[Pa]	Water vapor partial pressure difference
$\mu(\varphi)$	:[-]	Water vapor resistance factor depending on RH

The water vapor resistance factor depending on the relative humidity is described as follows;

$$\mu(\varphi) \, . \, \mu_0 - (\mu_0 - \mu_{100}) \, . \, \varphi^b \qquad (5)$$

where,

μ_0	:C-]	Water vapor resistance factor (φ=0%)
μ_{100}	:[-]	Water vapor resistance factor (φ=100%)
b	:[-]	Exponent
φ	:[%]	Relative humidity

The equation for the sorption isotherm curves, giving the relation between moisture content and RH is;

$$u(\varphi) = u_0 - \ln(1-\varphi)/d \qquad (6)$$

where,

$u(\varphi)$	:[%/%]	Moisture content depending on RH, vol.
u_0	:[%/%]	Moisture content (φ=0%), vol.
d	:[-]	Bending factor for the sorption isotherm curve

For each node representing a Ax - layer the moisture content at the new time "Δt+t", is the difference between the incoming and outgoing diffusion flux during the time interval "At" added to the moisture content at the previous time "t".

At each time step "At" the thermal conductivity for each material is determined depending on the average moisture content with equations as given in [3]. To achieve realistic results the values of the time interval At and layer thickness Ax are important. In this study; At = 7.2 seconds and Ax = 0.5 cm. For the calculations a computer program written in FORTRAN language is used.

3. Environmental conditions

The driving force for water vapor diffusion in an external wall construction is the water vapor partial pressure difference between the interior and exterior environment. As the water vapor partial pressure is depending on the value of temperature and relative humidity, they are the most important climatic elements for the assessment of the moisture performance of the wall. Solar radiation which is effective on the exterior surface temperature of a wall is also considered for the assessment.

At the meteorological station in Istanbul-Goztepe (lat. : 41°N, long.: 29°E), the outdoor temperature and solar radiation on a horizontal surface are recorded hourly, where as the relative humidity is recorded at 7.00, 14.00 and 21.00. The monthly average values for each hour of those outdoor climatic elements are used for the calculations.

In Istanbul, from November to March heating is needed. In this period, vapor diffusion is mainly from inside to the outside. The year with the lowest main outdoor vapor partial pressure at 7.00, 14.00 and 21 .OO for each of those months are selected from the meteorological records for the years 198 I-1990. This gives the most disadvantageous situation in terms of moisture performance under realistic outdoor environmental conditions. Because of the lowest average outdoor vapor partial pressure in the period when heating is needed February is the most critical month in Istanbul.

The equation of the idealized curve for the periodic fluctuating climatic elements, i.e. outdoor temperature and relative humidity is obtained with the "harmonic analyze" method.

The indoor temperature is considered to be constant at 21°C. The indoor relative humidity is taken from 50% to 80%, with a 10% increment, to show the effects of indoor environment on the intensity of water vapor diffusion and moisture performance of the wall.

Wind speed, affecting the thermal convection at both surfaces is considered to be at constant values inside and outside and so the values of the convection heat transfer coefficient, outside and inside are respectively; α_o = 23.26 W/m²°C, α_i = 8.34 W/m²°C.

4. Wall construction and material properties

The typical opaque component of a exterior wall construction for residential buildings in Istanbul consists of a **13.5** cm thick hollow burned clay brick with mineral rendering on both sides. A recent research has shown that adding a 5 to **8** cm thick thermal insulation, with the thermal conductivity of λ=0.04 W/m°C, to that existing opaque wall component is the most efficient retrofitting practice, from the point of view of energy and cost efficiency, [4]. It is recommended to apply the thermal insulation on the outer surface of the wall if the whole building is retrofitted and on the inner surface of the wall if only some flats of the building are retrofitted.

The walls examined in this study are the typical wall construction described above with a thermal insulation layer added either inside or outside of the wall. As the intensity of the water vapor diffusion is depending on the water vapor diffusion resistance factor and thickness of the insulation layer; a mineral fiber (glass fiber) with a relatively “low” water vapor diffusion resistance factor and a cellular plastic (EPS) with a relatively “high” resistance are the selected materials to use for retrofitting. Also the thickness of thermal insulation layer is alternatively taken as 5 cm or **8** cm. The absorption coefficient of the exterior surface of the wall construction is considered to be a'=0.7 for all alternatives. Also all alternatives are north facing walls. The material properties of the wall layers, which are used in the calculations are given in Table 1. The sections of the typical wall constructions with the inside or outside thermal insulation layer for retrofitting are in Fig. 1.

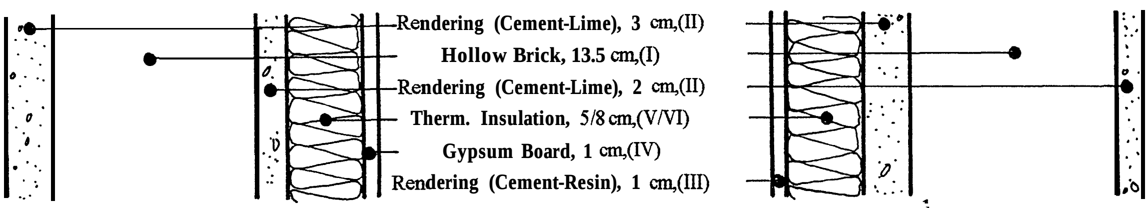
Table 1. The material properties of the wall layers.



a b

Figure 1. Retrofitted wall constructions studied (a: thermal insulation applied on the inner surface, b: thermal insulation applied on the outer surface).

5. Results

The moisture distribution at the surfaces and within the wall construction is an important criterion for the assessment of the moisture performance of the wall. The moisture distribution can be expressed either in moisture content or relative humidity. As the moisture content levels of various materials in a wall construction differ from each other it is not easy to show them on a graph at the same scale. To achieve graphical continuity in showing the moisture distribution within the wall construction, the relative humidity was preferred.

The moisture distribution, expressed in relative humidity (RH), within the existing wall constructions retrofitted either inside or outside with a mineral fiber or cellular plastic thermal insulation for the end of the month February are given in Fig. 2 to Fig. 5.

5 cm thermal insulation applied on the outer surface of the wall (Fig. 2):

When a glass fiber or polystyrene (EPS) thermal insulation is used for retrofitting and an indoor RH of SO%, the highest RH, for both alternatives, occurs as 100% on the inner surface of the wall that indicates surface condensation. Within the glass fiber layer the RH increases from 65% to 70% from the inside to outside. Whereas within the polystyrene layer the RH decreases from 80% to 65% from the inside to outside

5 cm thermal insulation applied on the inner surface of the wall (Fig. 3):

When a glass fiber thermal insulation is used for retrofitting and an indoor RH of 80%, the highest RH occurs as 95% in the wall section between the outer surface of the thermal insulation and rendering. Within the glass fiber layer the RH increases from 85% to 95% from the inside to outside. When a polystyrene (EPS) thermal insulation is used for retrofitting and an indoor RH of 80% the highest RH is 85% in the wall section between the outer surface of the gypsum board and thermal insulation. Within the polystyrene layer the RH decreases from 85% to 75% from the inside to outside.

8 cm thermal insulation applied on the outer surface of the wall (Fig. 4):

When a glass fiber thermal or polystyrene (EPS) insulation is used for retrofitting and a indoor RH of 80% the highest RH, for both alternatives, occurs as 100% on the inner surface of the wall that indicates surface condensation. Within the glass fiber layer the RH increases from 65% to 70% from the inside to outside. Whereas within the polystyrene layer the RH decreases from 80% to 65% from the inside to outside.

8 cm thermal insulation applied on the inner surface of the wall (Fig. 5):

When a glass fiber thermal insulation is used for retrofitting and an indoor RH of 80%, the highest RH is 100% in the wall section between the outer surface of the thermal insulation and rendering. Within the glass fiber layer the RH increases from 85% to 100% from the inside to outside. When a polystyrene (EPS) thermal insulation is used for retrofitting and an indoor RH of 80% the highest RH is 85% in the section between the outer surface of the gypsum board and thermal insulation. Within the polystyrene layer the RH decreases from 85% to 70% from the inside to outside.

6. Conclusion

The results show that the vapor diffuses relatively “easy” through the layers with a “low” water vapor diffusion resistance factor, like the mineral fiber thermal insulation, and it is accumulated in front of layers with a relatively “high” resistance, like mineral rendering. If the thermal insulation system is applied on the outer surface of the wall, the mean RH

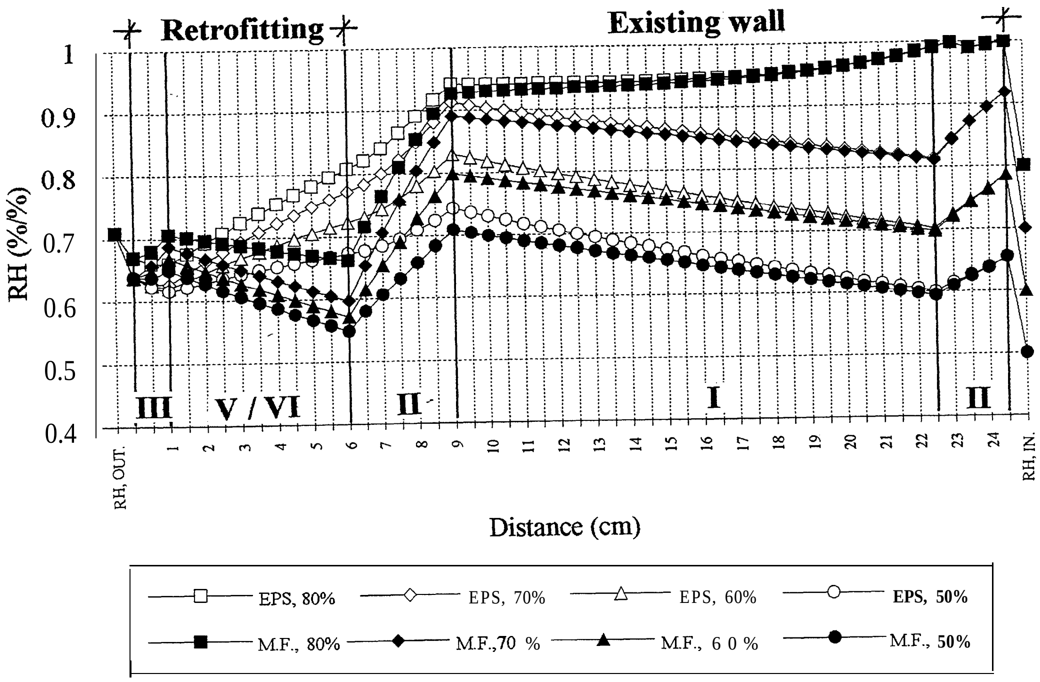


Figure 2. RH distribution in a wall retrofitted with a 5 cm thermal insulation (polystyrene:EPS or glass fiber : M.F.) applied at the outside surface with indoor RH of 50%, 60%, 70% or SO%, at the end of February, in Istanbul.

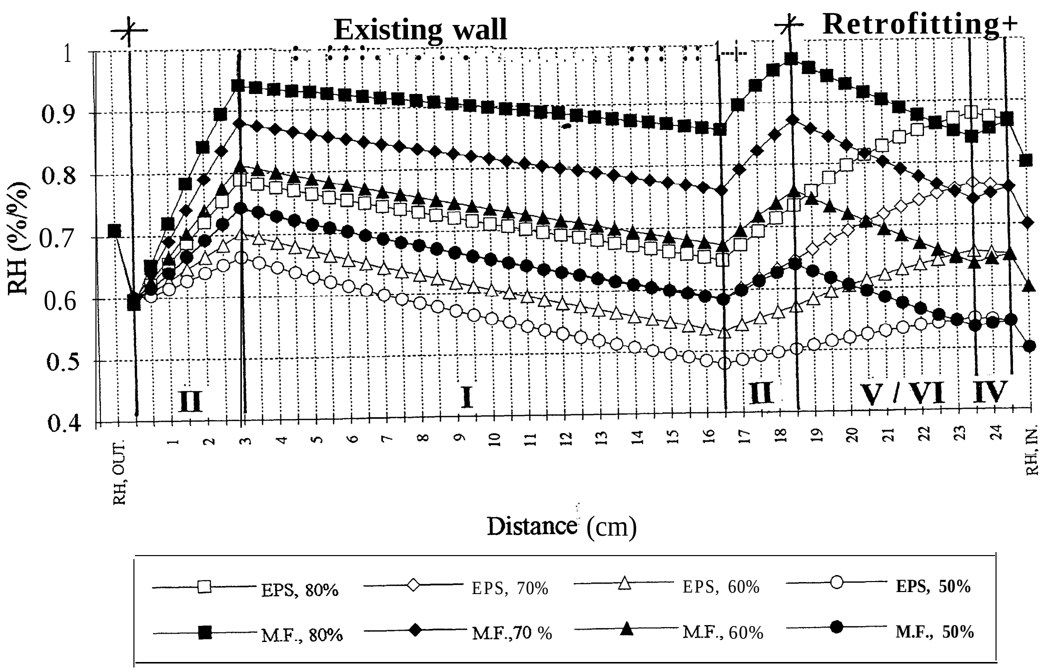

Figure 3. RH distribution in a wall retrofitted with a 5 cm thermal insulation (polystyrene:EPS or glass fiber : M.F.) applied at the inside surface with indoor RH of 50%, 60%, 70% or 80%, at the end of February, in Istanbul.

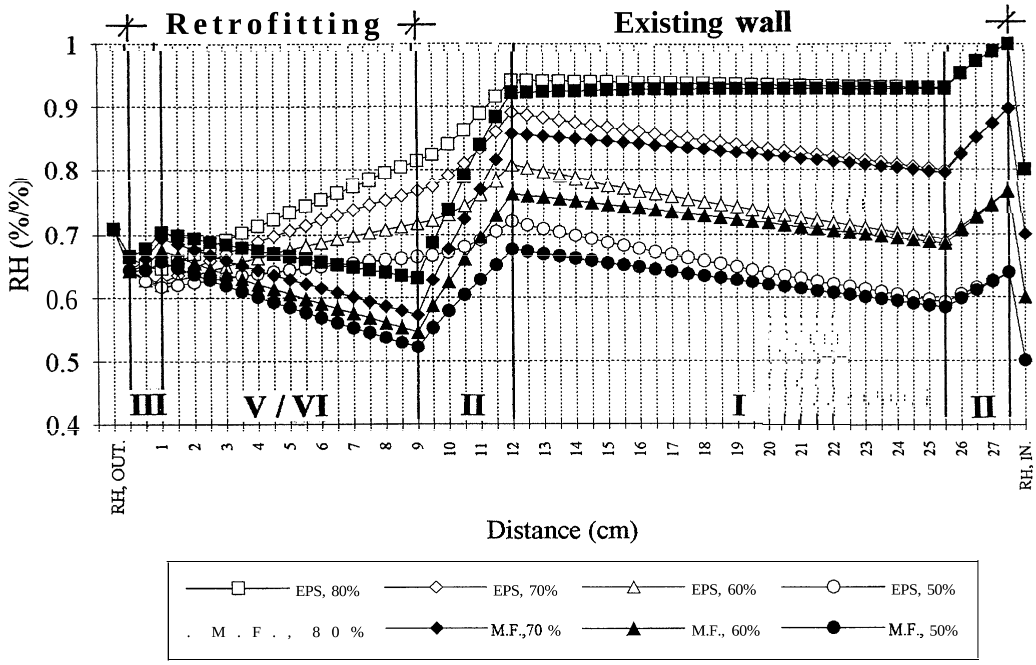

Figure 4. RH distribution in a wall retrofitted with a 8 cm thermal insulation (polystyrene : EPS or glass fiber : M.F.) applied at the outside surface with indoor RH of 50%, 60%, 70% or 80%, at the end of February, in Istanbul.

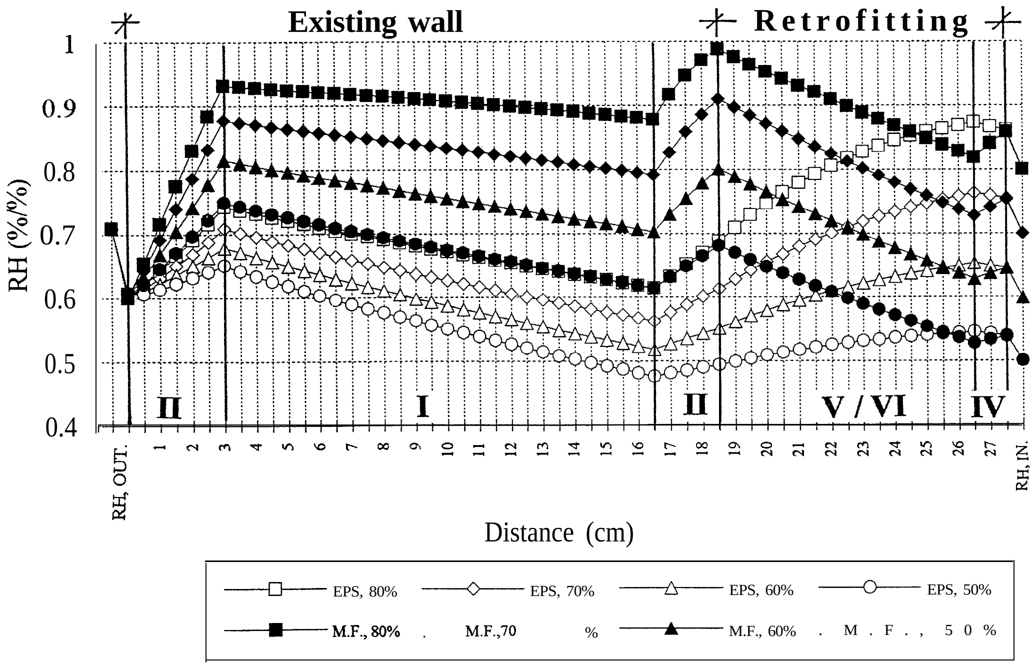

Figure 5. RH distribution in a wall retrofitted with a 8 cm thermal insulation (polystyrene : EPS or glass fiber : M.F.) applied at the inside surface with indoor RH of 50%, 60%, 70% or 80%, at the end of February, in Istanbul.

within the cellular plastic thermal insulation is higher than the mean RH within the mineral fiber material under the same indoor environmental conditions. If the thermal insulation system is applied on the inner surface of the wall the mean RH within the mineral fiber thermal insulation is higher than the mean RH within the cellular plastic material under the same indoor environmental conditions. So the increasing of the thermal conductivity value for cellular plastic thermal insulation applied on the outside of the wall and of mineral fiber thermal insulation applied on the inside of the wall is higher than the other alternatives, according to the higher amount of moisture.

When the indoor mean relative humidity is less than *60%* and the indoor temperature is 21°C, the moisture distribution within all studied retrofitted typical wall constructions of residential buildings in Istanbul is in the range of 80% to 50%, at the end of February. This amount of moisture can be considered as "allowable", thus it is not necessary to take any preventive measures during retrofitting. The same conditions appear also for retrofitting with 5 to 8 cm cellular plastic thermal insulation (EPS) applied on the inner surface of the wall when the indoor RH is less than 70%.

When the indoor RH is higher than 70%, the RH within the wall or on its inner surface is between 60% to 100%, for all examined retrofitting alternatives, except for the EPS insulation placed on the inner surface. To avoid internal or surface condensation in this period of the year some measures has to be taken. Either proper ventilation should be done to decrease indoor RH in both alternatives for the placement of the thermal insulation or a vapor retarder should be placed on the inner side of the wall for thermal insulation applied on the inner surface. The vapor retarders diffusion resistance should be at a level to retain diffusion, but not to cause excessive accumulation on its "inner" surface.

In designing a typical wall construction for retrofitting of residential buildings in Istanbul, the following points should be taken into consideration:

- If any kind of thermal insulation system is applied on the outer surface of the wall the indoor mean relative humidity should be less than 70% during the heating period, to avoid surface condensation.
- If 5 to 8 cm thick mineral fiber thermal insulation is applied on the inner surface of the wall the indoor mean relative humidity should be less than 80% during the heating period, to avoid condensation within the wall.

The effects of fenestration characteristics on the thermal performance of retrofitted residential buildings in Istanbul

A. Tavil, E. Özkan
Istanbul Technical University, Faculty of Architecture, Istanbul, Turkey

Abstract

A research project is set to investigate the thermal performance of the external envelope of existing residential buildings in Istanbul and to develop energy efficient systems for retrofitting external envelope of these residential buildings. In this context performance of the existing and the retrofitted windows are also analyzed. DOE-2.1E energy analysis simulation program is used for the simulation of heat loss and gain through the external envelope by modeling the buildings with their near environment, occupant, lighting and equipment schedules.

The annual energy performance of a window is not dependent on its instantaneous thermal and optical characteristics alone. In fact, it is strongly dependent on a large number of variables related to the total fenestration system. In evaluating the energy efficient rehabilitation of residential buildings, varying fenestration characteristics are effective on the total thermal performance of the buildings right along with the thermal insulation in the opaque components of the building envelope.

In this study, energy analysis of a retrofitted existing typical residential building in Istanbul will be presented and the effect of the variations in fenestration characteristics on the thermal performance of these buildings will be evaluated. In this analysis, fenestration variables which affect the thermal performance of the retrofitted residential buildings are considered in three main groups:

- Properties of the frame and glazing system.
- Orientation and shape of the building which is effective with the climatic variables.
- Optical properties of the window, shading devices and the user attitude for the management of the shading devices.

The effect of these variables on the annual heat loss of a residential building will be discussed with varying fenestration systems generally used in high story residential buildings in Istanbul. Finally, the thermal performance of the retrofitted external envelopes were studied for the evaluation of heating energy savings while sufficient thermal comfort in residential buildings was succeeded.

Keywords: Computer simulation, energy analysis, fenestration characteristics, residential building, retrofitting, thermal performance.

1 Introduction

A research project has been carried out to investigate the thermal performance of the external envelope of existing residential buildings in Istanbul and to develop alternative envelope systems for energy efficient retrofitting of these buildings, [1]. The study also covers to understand the effects arising from variation in the fenestration properties as types, sizes and shading of windows, infiltration, natural ventilation level and orientation of buildings. An appropriate range was selected for each variable to insure coverage of the expected variation typical in the multistory residential buildings in Istanbul.

A PC version of DOE-2.1E computer program., which is comprehensive enough for the energy simulation, has been used to analyze the thermal performance of residential buildings. Basically, two groups of data files, the weather data file of Istanbul and the building description input file representing the existing typical residential buildings in Istanbul, and the energy efficient alternative insulation and fenestration systems were prepared for the simulation. Finally, the thermal performance of the retrofitted external envelopes were studied for the evaluation of heating energy savings while sufficient thermal comfort in residential buildings was succeeded.

As windows are an important aspect in the design of most buildings, they play an important role in defining a building's aesthetics and occupant considerations of visual and thermal comfort. Windows are also a major factor in design because of their influence on building energy use. In case of residential units, which are heavily envelope dependent, windows strongly influence annual heating and cooling requirements, [2].

The energy performance of a window is not dependent on its instantaneous thermal characteristics alone. In fact, it is strongly dependent on a large number of variables related to the total fenestration system, climate and thermal and geometric characteristics of the building where the window is installed. Therefore, performance of a fenestration system should involve an assessment of these variables and interactions among them.

In recent studies, the effects of building and window orientation, window area, solar shadings, heat transfer (U-value), heating-cooling requirements associated with residential buildings are analyzed, [3, 4]. While the window frame, glazing systems, glass types, and the coatings on the glass such as for Low-E are considered for the assessment of the total U-value. Thus, the performance of a fenestration system is improved, [5].

The change in the solar radiation gain through windows is very effective on thermal performance of windows. A large percentage of windows have an internal and/or external shading or privacy devices such as blinds, drapes, shutters etc. Thus the magnitude of the solar gain also depends on the characteristics of these devices.

In this study, the fenestration variables which affect the thermal performance of the retrofitted residential buildings are analyzed in three main groups:

- Properties of the frame and glazing system.
- Orientation and shape of the building which is effective with the climatic variables.
- Optical properties of the window, shading devices and the user attitude for the management of the shading devices.

2 Description of the environmental variables and the residential building

In this study, an existing residential block representing the typical residential multistory buildings in Istanbul is chosen as a sample building. Istanbul takes place on the latitude of 41 degree north and the sample building faces to north. The built-up area of the sample building is 13*15 m and surrounded with eight residential blocks. They are specified in order to simulate the shading effect of the buildings in the neighborhood.

Hourly weather data of Istanbul, prepared as 'Test Meteorological Year-TMY' file according to the method given in ASHRAE Fundamentals, [6]. It contains one year of hourly data for each weather variable including direct-normal radiation, observed radiation, temperatures, atmospheric pressure, wind speed, sky cover etc.

2.1 Building specifications

Five story sample building having two housing units at each floor is 19.15*13.0 m in size. The total floor area is 1067 m^2 and the total building volume is 2881 m^3. A reinforced concrete structure, exterior non-bearing brick walls, single glazed wooden windows and a pitched roof are the typical elements of this residential block. A 1.5 m overhanging floor open to the outdoor environment surround the four sides of the building on the first floor. There are four balconies with 1.5x4.0 m size at each floor.

2.2 Internal load assumptions

The building is heated with a central heating system., therefore one temperature zone is accepted and the indoor temperature is assumed to be 21 °C. The floor weight with the furniture is taken to be 500 kg/m^2. The equipment load is calculated as 3 W/m^2 according to the sensible heat gain value of 350 W which assume that the cooking range and clothes drier are vented. The lighting type is incandescent and the maximum output is taken as 7 W/m^2 for each housing unit. The average lighting energy figure in a housing unit is assumed to be equivalent to using two 120 W bulb between 17.00- 18.00 hour, four 120 W bulb between 19.00-21.00 hours, two 120 W bulb between 22.00-24.00 hours and no lighting is used between 1.00-16.00 hours. Three people are living at each housing unit where the occupancy load is assumed to be 130 W/person, [6]. The building is totally occupied from 24.00 to 7.00 and 50 % of the resident is staying in from 8.00 to 23.00.

All the opaque components of the existing building are thermally uninsulated. For the retrofitted building, the exterior walls, the exterior overhanging floor and the roof slab are externally insulated with 5 cm expanded polystyrene with thermal conductivity of 0.035 W/mK for simulations. The interior floors are assumed to be adiabatic. This insulation system is determined as an energy efficient system in retrofitting of the existing residential buildings in Istanbul, [7].

3 Simulation

Numerical simulation is the approach used to study the effects of the fenestration characteristics of the sample building. DOE-2.lE Building Energy Simulation Program was selected for the simulation of the thermodynamic behavior of a building, to determine energy consumption and to test the sensitivity of this behavior to the selected building parameters, [8, 9].

Three glazing and four framing systems are considered for performance evaluation. For glazing, 3 mm clear single pane-(Gl), 3/13(air)/3 mm clear double glazing-(G2) and 3/13(air)/3 mm low-e double glazing-(G3) with the U value of 6.3, 2.8 and 1.8 W/m^2K, are used respectively. For framing, aluminum-without thermal break-(Fl), aluminum-with thermal break-(F2), wood-(F3) and vinyl-(F4) frames with thermal conductance of 17.2, 7.05, 2.46 and 1.8 W/m^2K are considered respectively. The transparency ratios are different in each facade. In order to study the effect of building direction on the annual heat loss, the sample building which is oriented to North (Dl), is rotated 45° and 1090°, oriented to North-West (D2) and West (D3).

The effects of varying window shading devices were studied by selecting four different white colored devices (Sl), (S2), (S3), (S4) with shading coefficients (SC) of 0.65, 0.55, 0.4, 0.2 and transmittance values of 0.65, 0.4, 0.2, 0.0, respectively, [5]. The internal shading device (Sl), which is an open weave fabric drapery is used to obtain outward vision and privacy. They are usually kept closed during day and night. The device (S2), which is a semi-open weave fabric drapery is used to control distracting inward view is usually kept closed during day and night time for the privacy. The device (S3), which is a close-weave drapery and (S4) which is an exterior roll blinds are used where protection from radiation is paramount with low SC values. In order to evaluate the effect of user attitude of managing the shading devices on the annual heat loss, four different management schemes are accepted; the shading devices are closed during the day and night (Rl), the shading devices are closed when the transmitted direct radiation exceeds 50 W/m^2 -(R2), 100 W/m^2 -(R3), 150 W/m^2 -(R4).

4 Discussion

In evaluating the effects of fenestration characteristics on the thermal performance of the retrofitted residential building, the annual heat losses for the building which were calculated according to the variables as glazing systems, frame types, shading coefficient, shading management of users and the building orientation are summarized in Table 1.

4.1 The effect of framing materials and glazing types on heat losses

The annual heat loss and the decrease in annual heat loss of the building according to the variation of the types of window framing and glazing are given in Figure 1. The annual heat losses of the building with single pane aluminum frame (without thermal break) window (F1G1) with a total U value 7.5 W/m^2K, and Low-E double glazed vinyl window (F4G3) with a total U value 1.7 W/m^2K are calculated as 142.6 KWh and 93.3 KWh respectively and thus, the maximum reduction in the annual heat loss through the building is realized 34.6 % by improving the window frame and the glazing system.

Considering the window framing materials, the maximum annual heat loss for the building that having windows with double-glazing and aluminum frame-without thermal break-FlG2 is 117.4 KWh. Using aluminum frame-with thermal break, wood frame and vinyl frame decrease the annual heat loss 6.5, 12.7 and 14 % respectively, Figure 1.

The annual heat loss of the building with vinyl framed windows and single glazing-(F4G1), double-glazing-(F4G2) and Low-E double-glazing-(F4G3) are 126 MWh, 101 MWh, 93 MWh, respectively They provide 11.6, 14 and 15 % decrease in annual heat loss when compared with the heat loss of building with aluminum framed and single-glazed windows-(F1G1), Figure 1.

Table 1: The calculated heat losses of the fenestration systems

4.2 The effect of orientation

The effect of orientation can be significant on the thermal performance of the building due to the window area and the window shading coefficient. The annual heat loss of the building with double glazed vinyl windows (F4G2) and open weave fabric draperies (S1) which are closed during day and night time for privacy are calculated 101 MWh, 100.5 MWh, 99.8 MWh, for different directions D 1, D2, D3, respectively. The effect of building direction on the annual heat loss is very low as the window areas of the facades are very close to each other and the variation of the building direction seems not to be effective for this situation. However, the variation of building direction would influence the annual heat loss when the transparency ratios of the facades differ.

4.3 The effect of window shading devices and shading management

In considering the solar heat gain through windows, shading devices are significant parameters with their optical properties. The annual heat losses of the sample building, which is oriented to north, having an external envelope insulation with 5 cm cellular boards and with vinyl framed double glazed window are calculated for four different shading devices S1, S2, S3, S4 which have shading coefficients of 0.65, 0.55, 0.40, 0.20, respectively. The annual heat losses of the building with these shading devices are calculated as 101, 103, 106 and 1 10 MWh when the devices are closed. In comparison with the exterior roll blind (S4), shading devices S 1, S2, S3 provides 8.1, 6.4 and 4 % decrease in annual heat loss. This shows that the energy savings increase due to the solar heat gain when the shading coefficient of the shading device increases.

The user attitudes for managing the shading devices are effective in the solar heat gain from the windows while providing privacy. The annual heat losses of the sample building with different shading devices S1, S2, S3, S4 and the way of management are expressed with the transmitted direct normal radiation, Figure 2. When the shading devices are kept closed during the day and night (R=O W/m^2) and kept open until the transmitted direct radiation reach 50, 100 and 150 W/m^2, the annual heat losses of the building with open weave fabric draperies (S 1) calculated as 10 1, 99, 98 and 97 MWh, while the heat losses of the building with exterior roll blinds (S4), are calculated as 110, 105, 103 and 101 MWh, respectively. By managing the shading devices due to the transmitted radiation, the decreases in heat loss are 2.0, 3.0 and 3.7 % for open weave fabric draperies and 4.5, 6.8, and 8.3 % for exterior roll blinds.

5 Concluding remarks

The results of the computer simulation analysis shows that the characteristics of window framing and glazing systems, and the optical properties and user management of shading devices can significantly reduce the annual heat loss of the residential building.

- The maximum reduction in the heat loss of the insulated building envelope, 34.6 %, is succeeded when the single pane aluminum framed window is replaced with Low-E double glazed vinyl framed window.
- Considering the double glazed window, if aluminum frame-without thermal break replaced with wood or vinyl frame, the annual heat loss decreases 13 and 14 %.

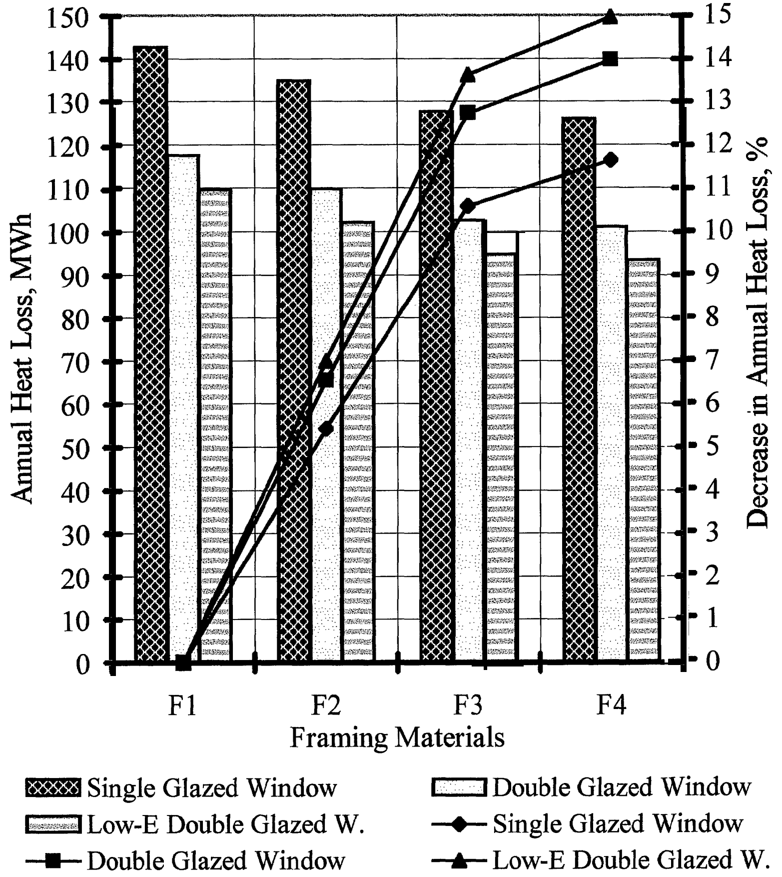

Figure 1: Effects of the window glazing and framing systems on the annual heat loss and decrease in building heat loss in percentage according to glazing systems

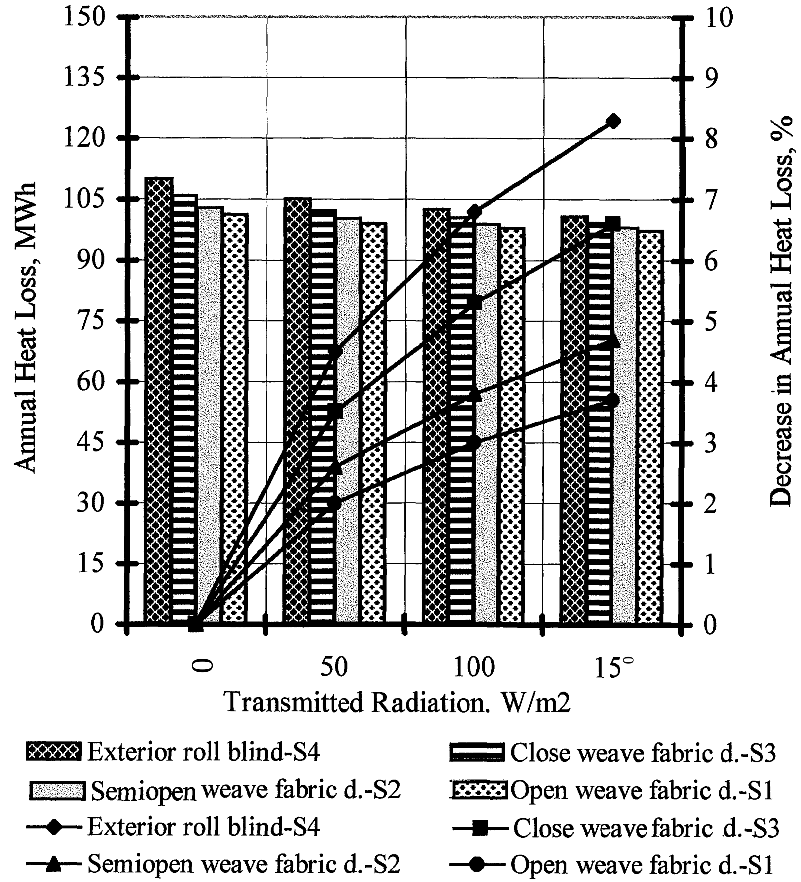

Figure 2: The effects of shading devices and management on the heat loss and the decrease in heat loss due to the transmitted radiation

- In comparison with the exterior roll blind with SC of 0.2, an open weave fabric drapery with SC of 0.65 as the internal shading device provides about 8 % decrease in annual heat loss. This shows that increase in the solar radiation gain due to increase in the shading coefficient increases the energy savings.
- By managing the shading devices according to the transmitted radiation that reaches 150 W/m^2, the decreases in heat loss are 3.7 % for open weave fabric draperies and 8.3 % for exterior roll blinds.

The fenestration system with the influence of these variables should be taken into consideration while designing the retrofitting of existing building fenestration system to control the thermal performance of the existing residential buildings.

Indoor Environment and Sustainable Development: A Crucial '*Buildings Partnership*'

Abstract

Compatibility of the indoor environment and sustainable development is not the issue! Not only is clear potential for compatibility evident between the indoor environment and sustainable development, this compatibility is not a matter of choice, it is a **sine qua non!**

Sustainable developmentfor ***buildings*** should be so defined that a quality indoor environment is a primary component. Moreover, sustainable development should not be considered as attained unless the quality of the indoor environment in buildings meets commonly accepted standards.

It is an undisputed fact that indoor environment quality in many countries has declined precipitously, even as the outdoor environment has improved due to stringent air emission standards. In the US, for example, as many as half of all buildings are estimated to have significant indoor environment problems; the US EPA further estimates that the indoor environment may be as much as ten times more contaminated than its outdoor counterpart. The statistics over the past 25 years paint a dramatic contrast. While gross domestic product increased by 99 percent in the US, emissions of the six leading air pollutants declined by almost 30 percent. In effect, the environmental problem shifted from the outside to the indoor environment.

How do we continue to improve our outdoor environment (also important) while, at the same time, we energetically focus on reversing the decline in our typical indoor environment? The tools for doing this are available, in the form of innovative technologies that destroy varied pathogens while removing a broad range of particulates and odor molecules.

Sustainable development and indoor environment are thus made compatible when the essential interactive relationships between innovative construction materials/methods, air distribution, appropriate mitigation technologies and our health, productivity and general well-being are recognized and implemented in buildings of all types.
Keywords: Indoor air quality, Indoor environment, air cleaning technologies

1. Introduction

What constitutes the largest single component in a building, whether new or old? Depends, you say, upon the type of structure. Not so. The answer is quite simply always the same, no matter what the structure components may be, or how old.

The largest single component of any building is, frankly, the indoor air it contains. This is- true today, and has been so for millennia, with the Pyramids perhaps the notable exceptions (but then, they were not designed for the living). Paradoxically, while the design and construction of buildings, from individual homes to the largest skyscrapers, has improved in almost every aspect over the course of human history, the quality of this most prevalent component has, in the view of many, actually diminished.

According to estimates by the U.S. Occupational Safety and Health Administration (OSHA) and the World Health Organization (WHO), nearly 50% of all buildings in the U.S. including homes, schools, offices, public buildings, etc. have serious indoor air quality problems [1]. The U.S. Environmental Protection Agency (EPA) states that today's buildings typically contain 2 to 5 times the pollutant levels of outside air [2]. Many energy efficient buildings are clogged with stale, polluted air, to include dust, mold, pollen, chemical pollutants, viruses, bacteria, odors and other harmful substances. Studies have shown that indoor air is up to 70 times more polluted than outside air [3]. These toxic air pollutants cause many physical and emotional symptoms; Dr. Jan Stolwijk of the World Health Organization recently stated that, "there is probably more damage done to human health by indoor air pollution than by outdoor pollution." [4]

This trend is occurring at a time when outdoor quality in many countries is improving as more stringent emissions standards reduce the levels of air pollution. In the U.S., for example, the past 25 years have seen a welcome reduction in emissions (29%) while gross domestic product rose by 99% [5]. Similar or better results have been achieved elsewhere.

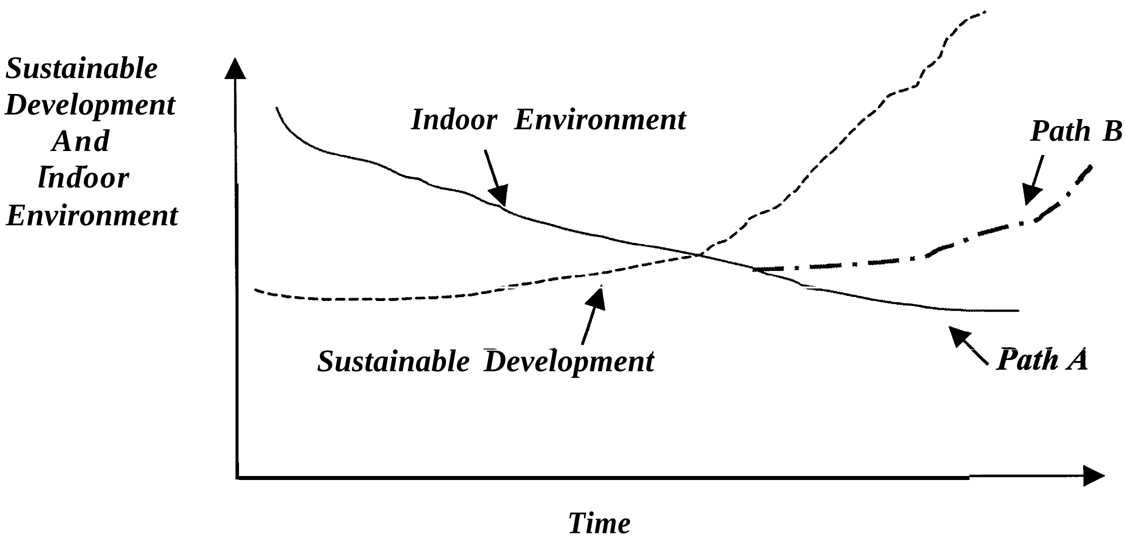
The causes of these countervailing trends are the stimulants for significant scientific research around the globe, by both public and private researchers. *The International Society of Indoor Air Quality and Climate* is surely representative of the many dedicated and excellent scientists and practitioners whose focus is the creation of indoor air quality that meets agreed upon health, comfort and productivity objectives. Among its stated objectives are to [6]:

- Advance the science and technology of indoor air quality and climate as it relates to indoor design, construction, operation and maintenance, air quality measurement and health sciences, and
- Facilitate international and interdisciplinary communication and information exchange

Our objectives today, through this paper, are somewhat different, perhaps not even truly scientific! Thus, we:

- Agree that both indoor air quality (IAQ) and sustainable development are even more vital today than in the past;
- Support the themes for improvement noted for this *CIB World Building Congress* as valid, important and musts for continued scientific perusal, but;
- Suggest that, in the meantime, *much can be accomplished with existing technologies* that is compatible with both sustainable development and the indoor environment! And, perhaps most ardently, we;
- Posit that the indoor environment and sustainable development must be viewed as inseparable and integral components of today's (and tomorrows) "building's focus."

A simple graphic gives a visual dimension to these points. The deterioration of the indoor environment need not occur as suggested by path A; rather, compatible and doable actions will enable simultaneous achievement of objectives related to sustainable development and the indoor environment (path B.)



Sustainable Development and the Indoor Environment- Mutually Exclusive?

"Sustainable Development" remains an elusive term, bending to a number of preferred definitions. Perhaps the most inclusive view, posited by the World Commission on Environment and Development, suggests that sustainable development is *"development that meets the needs of the present without compromising the ability of future generations to meet their own needs."* [7]

For the construction industry, sustainable development is likewise an elusive concept, with varied defmitions. The 1996 definition that emerged from the Civil Engineering Research Foundation's *International Research Symposium: Engineering and Construction for Sustainable Development in the 21st Century* provides perhaps the most globally accepted and inclusive civil engineering perspective of sustainable development, namely:

> *Sustainable development is the challenge of meeting human needs for natural resources, industrial products, energy, food, transportation, shelter and effective waste management, while conserving and protecting environmental quality and the natural resource base for future development* [8]

How do such global definitions challenge the indoor environment? What is there in the research and development of sustainable building components and practices that threatens the indoor environment? Is there, in fact, a fundamental clash?

Perhaps, at first glance. For example, the need to reduce building energy demand has resulted in the development of varied, innovative materials that effectively seal the building envelope, in effect, reducing the hitherto often significant exchange of indoor and outdoor air. Traditionally, building engineers relied on air changes up to 50% of building air per one-hour period [9]. A significant issue arises as a consequence of this improved "seal," namely chemical contaminants from varied indoor sources, including construction materials. Add to this the possible introduction of external air laden with chemical contaminants, such as automobile emissions and biological contaminants (pollen, viruses, bacteria, spores, etc.) from varied sources and the making of a chemical/biological cocktail becomes reality.

But, do the above examples represent an impasse or merely challenges that require closer coordination and improved understanding of the complex interactions that are inherent in building design, construction, furnishings, operations and maintenance? We argue the latter! Thus, there is no basis, in our view, for the premise that sustainable development and the indoor environment are incompatible. Our basis for this assertion encompasses, instead, continued research and development of mitigating technologies/procedures and common sense approaches that utilize what is now available to mitigate indoor air pollution and thus provide the required and desired indoor environment.

2. The Indoor Environment (IAQ) Problem

How serious is today's indoor environment degradation? There are really two dimensions to this question. We can define the first as the recognized impact of degraded indoor air quality while the second is more elusive and encompasses health and comfort effects that are not immediately obvious. Both are important since the majority of the world's people spend between seventy and ninety percent of their lives in the indoor environment.

In the first category are those impacts generally labeled as either "sick building syndrome" (SBS) or "building related syndrome" (BRI). Both are recognized as significant, with perhaps nearly one-third of all constructed buildings, worldwide, being impacted by SBS/BRI according to the World Health Organization [10].

The causes of SBS are typically labeled as "unknown" while the impacts are anything but! These include dizziness or nausea, headaches, eye, nose and/or throat irritation, skin disorders, fatigue, loss of concentration, etc. Of significance, the symptoms are confined to the structure and relief occurs after leaving the building.

BRI involves identifiable causes, attributable to airborne indoor contaminants. Unlike SBS, the relief/recovery may not occur upon leaving the premises. Again, symptoms may include coughs, fever, chills and muscle aches.

The second category, in our opinion, involves the more elusive concept of optimality. In other words, ***what are the optimal "operational conditions"*** in a building in which the indoor environment is optimized? Is it possible to quantify the optimal health, comfort or productivity associated with such a structure? We do not propose to answer this, merely to suggest in concrete terms, later in this paper, that steps towards optimality are possible.

Finally, we must acknowledge the difficulty in separation of complaints that actually derive from other sources such as allergies, job-related stress, allergies and other psychosocial factors. These clearly may create impacts that in no way should be associated with the building itself.

3. Indoor Environment Solutions

The answer to indoor environment improvement is obvious; remove the cause(s) or source(s)! The difficulty comes in determining "what" and "how."

A traditional response is to increase ventilation rates. This solution, however, has several dis-advantages. First, it is counter to the need for energy efficient solutions. Ventilation carries the penalty of moving large amounts of air at significant energy usage. Secondly, rather than eliminate pollutants, these are simply transferred to the outside environment for possible transfer into other buildings. Thirdly, the higher velocity associated with such increased ventilation rates may, itself, contribute to increased pickup and distribution of unwanted substances. And, finally, heating and ventilation systems are complex systems, requiring significant maintenance and careful adherence to proper operational procedures. Increasing reliance on this method therefore entails both added energy demand and a proper focus on operation and maintenance.

Another response is to identify and remove pollution sources. This may encompass a variety of sources of volatile organic compounds (VOCs) that may derive from carpets, upholstered furniture, computers and copying equipment, solvents, etc. While laudable, one difficulty with this approach is that it also removes many needed or desired products that may, if eliminated, lower productivity or otherwise impact the function of the building in question.

Another solution is air cleaning! This solution takes many forms, from the typically inexpensive but limited efficacy furnace filters to high performance (HEPA) filters to more capable air cleaning systems that do not rely entirely on filters for air purification.

It is this latter family of air cleaning systems that we believe ensure a high quality indoor environment, ***are available now*** and are fully compatible with sustainable development.

There are four essential tasks required to provide and maintain indoor air quality:

- Fresh air exchange (ventilation);
- Elimination of dust, pathogens, pollutants and other airborne substances;
- Replenishment of oxygen, and;
- Maintaining an appropriate ionic balance.

As already noted, ventilating a building with enough fresh air from the outside to replenish oxygen and maintain ionic balance requires a large amount of heat and electrical energy and may bring additional pollution in with the outside air. Filtering the air removes only some of the airborne particles and increases resistance (pressure drop) which requires more energy. None of these measures addresses the critical issue of maintaining the ionic balance of indoor air.

Ions are charged particles in the air that are formed when enough energy (light, heat or other forces) acts upon a molecule such as oxygen, carbon dioxide, water or nitrogen to force the ejection of an electron. The displaced electron attaches itself to another molecule, thereby creating a negative ion. Although negative and positive ions must exist in balance, it is the negative ion of oxygen that has the greatest effect on human behavior. Remember the feelings you may have experienced near the shore, or by a waterfall or high in the mountains? These are locations where the highest concentrations of oxygen ions are found. Normal ion count in fresh country air is 2,000-4,000 negative ions per cubic centimeter (cm^3) [11] or a space about the size of a cube of sugar. At Yosemite Falls, over 100,000 negative per cm^3 have been recorded. Typical building air contains 300-500 negative ions per cm^3, [12] while the Los Angeles freeways have been measured at levels far below 100 negative ions per cubic centimeter. These negative ions or so-called, “small ions” have only a lifetime of two seconds, in effect, they lose their charge very rapidly. Current technology exists that builds up “medium ions” of up to 60 molecules, known as oxygen “clusters”, with a lifespan averaging 2 1/2 hours [13].

Since at least the 1970’s, medical researchers have recognized the beneficial effects of negative ions on human behavior [14]. Irritation, tension, exhaustion and hyperthyroid response along with depression, anxiety, headaches and decreased physical and mental functions have been shown to be alleviated or totally eliminated by increasing the negative ion count in the air. ‘Negative ions are now known to increase alpha brain waves and enhance brain wave amplitude. This increases the speed with which nerve impulses can travel along the synapses of the brain and the nervous system, which translates into a higher awareness level and a greater sense of personal well being. The high ionic level also kills germs and pathogens in the air, which is an important, discernible health benefit.

4. Current Barriers that stifle Attainment of an Enhanced Indoor Environment

While the case for applying innovative technology to improve indoor air quality is obvious (diminished health costs alone justify the effort,) there are formidable barriers that challenge effective implementation, including:

- "A lowest first-cost" mentality or perspective shared by owners, builders, etc.;
- Disconnection between owners, designers and constructors;
- A lack of clearly demonstrable cost/performance benefits for improved indoor air quality;
- Low profit margins inhibit innovation and risk taking;
- Lack of regulatory mandates or voluntary compliance support
- Absence of insurance or health authority encouragement.

Given the low profit margins of U.S. construction and building maintenance, averaging only 2.5% per the Civil Engineering Research Foundation, [15] it is unlikely that innovative building air quality technology will routinely be specified in the United States. Traditionally, Europe leads the world in voluntary compliance and related technology application. A good example is the recent development of an innovative photo-oxidation process for VOC/HAPs abatement and the bi-polar indoor ionization technology that has been used extensively in many public and private German buildings for decades [16].

5. Conclusions/Recommendations

As we look back on human progress in this century, we have much to be thankful for. Many, albeit not yet the majority, enjoy a standard of living inconceivable a scant one hundred years ago. There is hope that these improvements will, in the years to come, encompass more of humanity. Nonetheless, progress has come at a high cost to our environment, both indoor and external. It is the recognition of this impact that has prompted, indeed mandated, a focus on sustainable development.

Buildings are no exception. Fortunately, thousands of skilled researchers and practitioners around the world not only recognize this need but also have embraced sustainable development in every aspect of building life-cycles.

The indoor environment is an essential component of every building and thus, an essential focus for sustainable development. Fortunately, the indoor environment is truly compatible with sustainable development, and, even more significant, amenable to both immediate solutions and continued research and development of even more effective solutions. As practitioners however, we must not lose sight of the fact that, in the end, the single most prevalent component of buildings, the indoor air, is also our responsibility.

Risk management for sino-foreign joint ventures in the Chinese construction

L Y Shen

Henderson China Holdings Limited, Hong Kong

Abstract

With the application of competitive tendering methods for the procurement of construction projects, the construction industry in China is developing towards the international procurement practice, and such development has attracted many foreign firms into the construction market through the formation of sino-foreign joint ventures. However, as the national economy system in China is still being reformed from the purely planned economy system to a market-orientated system, there are many obstacles and risks affecting the operation of joint ventures. This paper examines the development of the sino-foreign construction joint ventures in China. It presents the risks to the joint ventures in the procurement practice. Effective procurement strategies for sino-foreign construction joint ventures to manage risks have been studied through the investigation of some case studies.

Key words: China, Competitive Procurement, Construction Market, Joint Venture, Risk, Risk Management

1 Introduction

The competitive procurement practice in the Chinese construction has developed quickly. Before 1984 when tendering system was applied to the industry, there was almost no construction contracts procured through tendering [1]. In 1989, about 47,650 projects used bidding for contracts, which accounted for about 13% of the total construction projects in China [2]. In 1995, the number of project contracts applying bids increased to 34.5% of the total construction projects [3]. The selective tendering is the most popular method used in the industry. The application of competitive tendering methods has brought rapid development of other construction sectors in the construction industry in China, including collective construction firms, rural construction teams and sino-foreign joint ventures. The number of joint ventures has been increasing. The ever-growing Chinese construction market become more open to overseas investors and contractors, and will continue to provide good opportunities to foreign firms. According to its 'Ninth Five-Year Plan for the National Economy and Social Development and the Long-term Development Planning to the Year 2010', the Chinese government will fully establish the socialist market economy system within the future 15 years. Official report indicates that during the ninth 5 year from 1996 to 2000, the total fixed asset investment in China will be US$1560 billion with about 60% for construction works. During this period, the construction area for various new houses will reach 1.4 billion square metres, the investment in municipal public utilities will be up to around US$70 billion, and 4 billion square metres of urban and rural housing will be renovated [4].

However, as the national economy system is still being reformed from purely planned system to market-orientated system, and the marketing mechanism for business is still being established, there are many obstacles and risks affecting the operation of sino-foreign joint ventures. In a typical joint venture, the overseas party is usually responsible for the provision of the majority of finance, and the local partner will normally provide facilities, land, labour, or other assets. The overseas party is in a more risky situation as they could not easily take with them the assets invested if they really find not worth of continuing and want to withdraw. It is important for a joint venture to understand the potential uncertainties to the operation of the venture and to develop proper procurement strategies for managing the risks. Little literature appears to be done in this field. It is the major objective of this paper to study the risks involved in sino-foreign construction joint ventures in China, and to investigate procurement strategies for managing the risks.

2 Development of sino-foreign joint ventures in the Chinese construction

Sino-foreign joint ventures are promoted in China to invest in all economic sectors for attracting foreign capital, advanced technology, and the expertise that can be transferred to the indigenous Chinese partners. There are mainly two types of sino-foreign joint ventures practicing in China.

2.1 Equity joint venture

An equity joint venture is actually an enterprise jointly invested by a Chinese firm and a foreign partner. Both two partners jointly invest and manage the business operations. Normally, profits and losses are shared according to the equity stake, the proportion of which for the foreign partner is usually not less than 25% [5]. Partners' responsibilities and benefits are governed and protected by the 'Law of the People's Republic of China on Joint Ventures Using Chinese and Foreign Investment'. As a limited liability enterprise, an equity joint venture has legal-person status. Organisations enter into an equity joint venture often plan to establish a long-term business in China.

2.2 Cooperative venture

Cooperative venture is sometimes called contractual joint venture in which each party enters into a contract but acts as a separate legal entity and bears its own liabilities. Such joint venture may take any co-operation form agreed between the two partners, with each party's rights and obligations specified in the contract. Usually the Chinese partner would provide contributions as part of its stake in the kind of land, natural resources, equipment, labor force and public utilities, etc. The foreign partner usually provides capital, advanced technology, key equipment, materials, management skills, etc. The cooperative joint venture is usually in a more flexible form of investment bound by fewer statutory provisions. Cooperative joint venture usually is project based. This kind of enterprise can be developed quickly to take advantage of short-term business opportunities and dissolved when they complete their projects.

2.3 Development of sino-foreign construction joint ventures in China

Almost all the foreign firms in China entered into the Chinese construction market through forming sino-foreign joint ventures. There are very few wholly foreign owned enterprises as they will have to go through many procedures for approval, which will take a long period of time. Because of the cultural and language barriers, few overseas companies will like to go through these procedures by themselves. The government has been encouraging foreign firms to set up joint ventures with local firms. As it is in line with the government's interest, a joint venture will find much easier to pass through approval procedures. Furthermore, wholly foreign owned firms are strictly limited to work with certain projects. China is cautiously opening its construction market to overseas. Even joint ventures are still only allowed to participate certain projects such as foreign invested projects, the World Bank projects, and the projects concerning with advanced technology [6].

The rapid development of applying competitive tendering approach has provided opportunities to overseas firms. In Shanghai, for example, there was no foreign contractor up to 1984 when the system of tendering was just introduced to the Chinese construction industry. But, by 1994, 72 foreign contractors and 3 1 designers had entered into Shanghai construction market through forming sine-foreign joint ventures [5]. Up to the middle of 1996, the Ministry of Construction of China and municipal governments had given licenses to 118 large foreign firms who, in collaboration with local firms, have implemented more than 140 large construction projects. And significant number of medium projects is obtained by joint ventures [2]. Joint ventures in the Chinese construction are becoming a major party in the Chinese construction.

3 Risks to the sino-foreign joint ventures in the Chinese construction

Whilst construction industry is usually said to involve more risks and uncertainties, it appears that a sino-foreign joint venture in the Chinese construction is subject to much more uncertainties because of the special characteristics of the Chinese construction market. Several special risk areas are presented as follows:

3.1 Risk of finding partner

As there are many different overseas and domestic construction companies with different level of quality and capability, both two parties in a joint venture will face the risk of having an 'uneasy' partner to work with. Usually, overseas companies like to find their partners from those large state-owned companies. However, these companies often have a complicated and bureaucratic system, and their top managers are usually appointed by government. It happens that the top management staffs are changed suddenly. Furthermore, there is a risk that large companies have huge registered capital and assets but little real cash flow. The improper arrangement of partner can lead serious disputes, consequently, substantial losses can occur. In a commercial building project developed by a sino-foreign joint venture in Shanhai, the foreign partner suggested to select the main contractor through selective tendering, but the local partner insisted to employ its own construction team as the main contractor for the project. Due to the application of inappropriate technology and building methods by that main contractor, settlement occurred to the adjacent factory and its production line was damaged during the basement excavation of the project. The factory owner sued the joint venture and requested for damages. The main contractor denied the liability and refused to attend any meeting for negotiation and settlement. Finally, the case was settled through mediation and the joint venture had to reimburse the factory owner for the damages. During the construction, it was also very difficult to control the main contractor on time and cost aspects such as the negotiation on rates of new items as the main contractor was the local partner's own subsidiary firm.

3.2 Legal and policy risk

The market economy system is still being established in China, and governmental policies are subject to various changes. There are many provisional policies and legal regulations issued by both the central government and local governments, which will be revised or updated as the reform progresses. The variations of governmental policies and legal regulations can have significant impact on the financial picture of a joint venture project. This can be demonstrated by a particular case. A joint venture project is located in an old city in Guangdong province, and over 1600 families used to live in the project site. The local government planned to redevelop the site into a high class residential area. One of the critical issues in the contract arrangement was about the resettlement for those who used to live in the area. According to then governmental resettlement regulations, those residents affected by the construction of financial, commercial and high-class residential buildings should be permanently resettled to the area outside of their original living location. The resettlement work started accordingly. However, after less than half of the families having been resettled, the local government issued the new resettlement policy. By new policy, if the demolition of the old building is caused by the construction of residential buildings, those residents affected should be resettled back to their original living district upon the completion of the redevelopment. The new policy is in effect and applicable to all projects irrespective of the date of signing contract. Due to the sudden change of the resettlement policy, the saleable floor area from the development has been dramatically reduced. As a result, the profit of this joint venture project is expected to drop by over 50%.

On the other hand, as local governments issue various “additional”, or most often “temporary” policies, there is a risk that some of these local policies may not be recognized by the central government. The implementation of joint venture projects according to local policies may not satisfy the central governmental policy, consequently, the investor may suffer from such policy variation.

3.3 Technical risk

The operation of a joint venture is also subject to commonly defined technical risks, such as mistake in design; improper technology; shortage of materials, plant and labour; damage to built works; injures and accidents to working staff; damages and accidents to third party; natural disaster, etc. However, one major technical risk involved in a sino-foreign joint venture project is due to the different building practice applied in China and overseas. In a commercial building project developed by a joint venture in Beijing, risk happened due to the difference of technical building practice. The incident was about the co-ordination for laying E&M conduits, which was undertaken by a nominated E&M subcontractor.

Under the main contract, the main contractor would be responsible for attending to the works of the nominated subcontractors, which is a usual arrangement in international practices. However, during the normal inspection of the construction works, the joint venture’s work supervisor received the complaint from the E&M contractor, that the masonry workers hired by the main contractor were damaging the vertical conduits laid earlier by the E&M contractor. The supervisor went to the spot to check and found that all the vertical conduits were bent outwards from the structural brick walls instead of having concealed in the walls as required by the drawings and specification. When questioned, the local workers setting the brick walls revealed that the common practice of finishing the works in China was in the pattern of one trade following another. In this case, the sequence should be to erect the structural brick walls, to make the chases for the conduits, to lay the conduits by the E&M contractor, and to apply finishing to conceal the conduits. When the masonry workers started their work, they found that vertical conduits were installed and obstructed their operation. They therefore bent the conduits (some conduits were even pulled out and set aside) in order to make way for setting their brick wall. When the supervisor discussed the case with the main contractor, the main contractor blamed E&M contractor and asked for compensation for abortive works. As the different practice has not been speculated in the contract, the joint venture developer has to compensate the main contractor.

3.4 Risk in bidding

The competitive tendering approach has not yet been fully established in the Chinese construction industry. As many small or medium sized state-owned construction companies have no competition strength, the government departments have to protect them by assigning them certain projects for them to survive. Thus the current procurement practice in China is in fact a partial competition system which includes both competitive tendering and administrative assignment. It appears that only World Bank and Asian Bank Projects and some other large projects are procured through open tendering approach. The local protectionism affects to a large extent the adoption of the open tendering method. Provincial localities normally issue various regulations limiting the participation of external construction firms to tender for local projects. The sino-foreign joint ventures are restricted to certain kinds of projects [1],[5]. The partial competition practice brings the poor transparency in the tendering process, in which a joint venture can easily loss.

4 Risk management strategies for the sino-foreign construction joint ventures

Risk management is usually defined as a system including risk identification, risk analysis and risk response. Previous studies have provided a wide range of risk management strategies for the businesses in the construction industry. Typical strategies are suggested as contractual risk transfer or allocation, risk reduction by adopting alternatives, risk control or taking by applying risk premium, etc. [7]. Whilst all these methods are applicable to managing risks involved in a sino-foreign joint venture in the Chinese construction, the following studies will investigate several typical risk management approaches applied in China.

4.1 Good relation with local government

To operate a sino-foreign joint venture in the Chinese construction, it is extremely important to maintain good relationships with local government. A Hong Kong developer formed a cooperative joint venture with a local state-owned company for developing a multi-function building in Shanghai. Upon the completion of two-third of the project, the government proposed to extend a ramp for an existing bridge that is adjacent to the project. This proposal would result in the blocking of the shop-front of the building facing the ramp extension, and the red line of the site would have to move backward. However, as the joint venture has established very good relationship with the local government, the negotiation has led to the change of the direction of the ramp extension. Consequently, not only the shop-front of the building will not be blocked, but the value of the building has also been enhanced as the new ramp improves the traffic flow, thus enhances the location value of the building.

4.2 Contractual risk allocation in equity joint venture

An equity joint venture is to look for a long-term business, thus it is important to establish an organisation in which risks are properly allocated. Main concern must be given on who is more capable to control risk. In a practical case, the foreign partner successfully transferred all technical risks, and protected safely his interests through contractual arrangement. The local partner is responsible for the management of construction and operation of the project. The project is a power plant with the capacity of 2x150MW located in Southwest China. The total investment for the project is about US$290 million. The project is offered to an equity sino-foreign joint venture with 20 years of cooperation period. The local partner is a state-owned power company, and the foreign partner was selected through selective tendering among six international companies. The contract includes the following major terms:

Investment amount: 38% equity, 62% shareholder loan;
Equity IRR not less than 15%, interest rate for loan not less than 10%;
Preemptive amortization for the investment by foreign party;
10 years payback period,
Local partner being responsible for the extra costs due to the construction risks including delayed time, poor quality, etc.;
Local partner assuming all operation and maintenance risks to ensure that the operation hours of 5000per year.

Thee joint venture also buys insurance against the risk of breaching contract by either party.

4.3 Risk control in cooperative joint venture

Most of the sino-foreign cooperative joint ventures are project-based ventures. Project management procurement system is widely applied in controlling risks in such joint ventures. For a typical sino-foreign cooperative joint venture on commercial or residential building projects, the foreign party will assume the duty of overall project management. The main contract of construction work will be offered mainly through negotiation to a local construction company, suggested by the local partner of the joint venture. Upon foreign party's request, selective tendering method can be used for selecting the main contractor. Sub contracts will be normally offered through selective tendering process, in which both overseas and local firms can be affected. The professional consultant is usually recommended by foreign party, and building supervision team will be from the local party's advice. In fact, foreign party in such arrangement takes the role of project manager, and the local partner assumes the role of construction manager who is responsible for all technical risks. Such arrangement has been found very effective in controlling joint venture risks.

4.4 Share of legal risk with relevant government department

As many government departments have their own subsidiary construction companies, it is an effective way to appoint such companies to undertake works in joint venture projects. For example, in the previous case discussed in the section of legal risk, the joint venture has appointed a subsidiary company of the Construction Commission of the local Government to undertake the resettlement work. Through this arrangement, most of the risks related to the resettlement work have been passed over to this subsidiary company. The joint venture believes that the governmental department will re-adjust the relevant policies in finding a way out because of the pressure from its own subsidiary company. Hence, even though that issue has not yet been resolved, a moderate solution can be expected.

5 Conclusion

This study demonstrates that the huge construction market in China has attracted many foreign firms since the beginning of 1980s. Majority of them works in China by forming joint ventures with local partners. The participation of foreign firms has contributed significantly to the development of the competitive construction procurement practice in China. There are a number of risk areas affecting the operation of construction joint ventures in China. This paper has identified the major risks affecting the sino-foreign joint ventures, such as legal and policy risk, technical risk, partnering risk, etc. It is important for a joint venture to have a clear picture of the future risk profile involved in their businesses in order to take proper risk management strategies.

Eindhoven University of Technology, The Netherlands

Abstract
Two aspects will be stressed in the frame of this topic:
The Procurement Aspects and the Aspects of Conflict and Dispute Resolution.
The Right for Environment - to introduce the following aspects - is not only the consequence of care-taking for Nature as an admirable phenomenon, but also as a source of nearly all what is needed for humankind of today and tomorrow. The legal practises - of course - have not only to fulfil1 the current valid laws and guidelines, but they have to be based on an ethic and even altruistic behaviour.
Against the background of so many shrinking resources, we have to look for sustainable and renewable sources and have to choose for those building practises which clearly contribute towards sustainability. The important procurement problems can be handled in research as well as practise by the applications of the Material and Energy Choice and Selection Method, which is summarised in a Matrix. This Matrix - as a rule of thumb - can help to choose consciously concerning the bigger or lesser effects and side effects which sooner or later will go hand in hand with the choosen practises and technologies.
Since building is teamwork, always - except an hermit alone builds for himself - Conflict and Dispute Resolution is most important. The Method Holistic Participation - MHP - serves this purpose excellently and can be applied for problem solving of nearly each complex task, in which different, even opposing parties will participate. Based on very old experiences, firstly applied by Konrad Wachsmann and Walter Gropius in Building Technology in the fourties and further developed by the author, it is possible to use this method effectively in order to reach common solutions mainly by consultation and in consensus.
Beside the importance of Legal and Procurement Practices and the Right for Environment it will at least be necessary to consider Management as a key to get the' things done. The Indoor Climate as the reason wherefore we build and Materials and Technologies, which are strongly related to procurement problems, which are 'responsible' for the materialisation and realisation as well - have to be taken in consideration.
Together with a responsible view on those fields, it will be a 'conditio sine qua non', to handle the absolute principle of care-taking in legal and procurement practises, considering the whole of humankind in the radically smaller getting world.

Keywords: Method holistic participation and care-taking

Procurement Sustainable Building Practice

Two aspects will be stressed in the frame of this topic:

The Procurement Aspects and the Aspects of Conflict and Dispute Resolution.
The Right for Environment - to introduce the concerned aspects - is not only the consequence of care-taking for Nature as an admirable phenomenon, but also as a source of nearly all what is needed for humankind of today and tomorrow. The legal practises - of course - have not only to fulfil1 the current valid laws and guidelines, but they have to be based on an ethic and even altruistic behaviour.

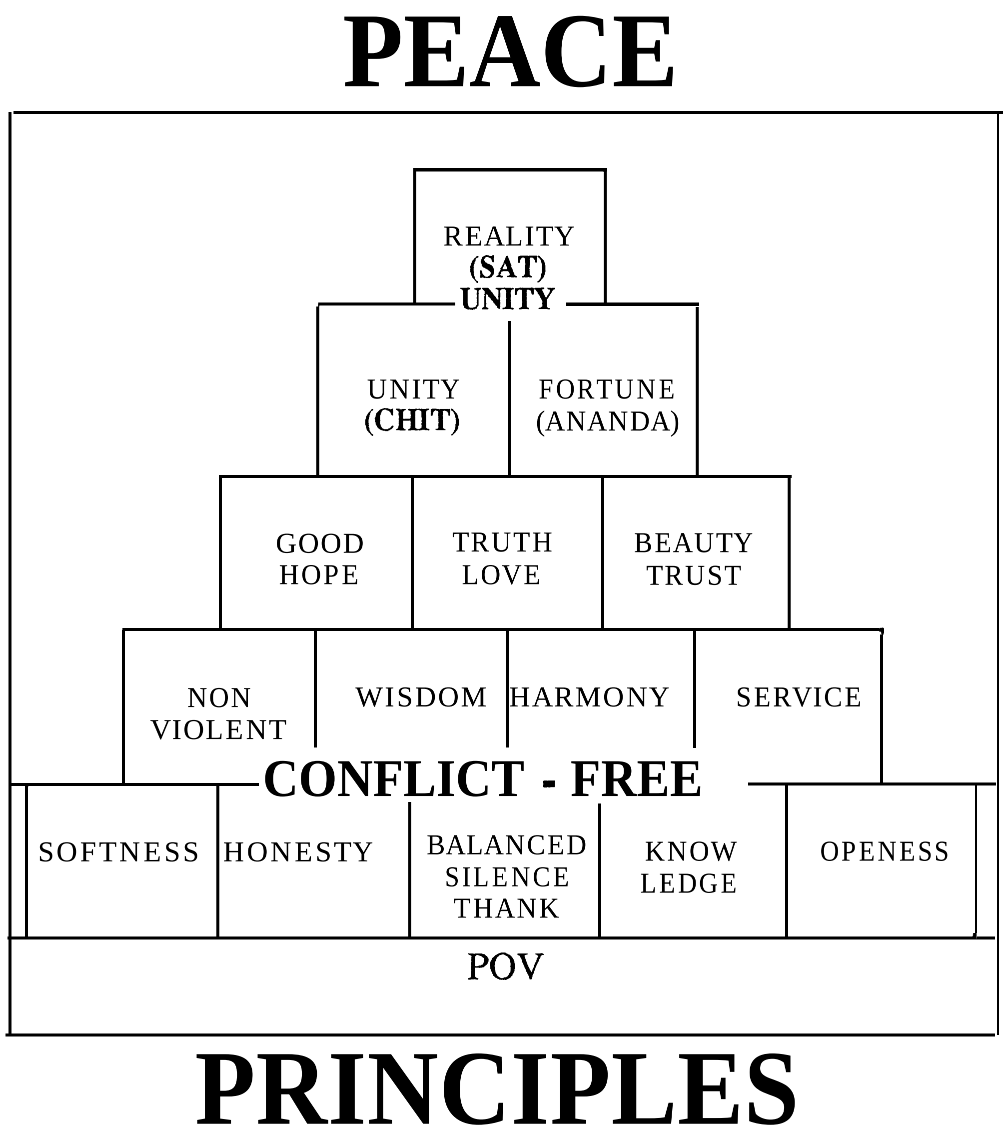

Figure 1
The Pyramid of Virtues shows the behaviour qualities which have to be respected in order to give to Science and Technology a direction towards responsible processes and results.

Against the background of so many shrinking resources, we have to look for sustainable and renewable sources and have to choose for those building practises which clearly contribute towards sustainability. The important procurement problems can be handled in research as well as practise by the applications of the Material and Energy Choice and Selection Method, which is summarised in a Matrix. This Matrix - as a rule of thumb - can help to choose consciously concerning the bigger or lesser effects and side effects which sooner or later will go hand in hand with the choosen practises and technologies.

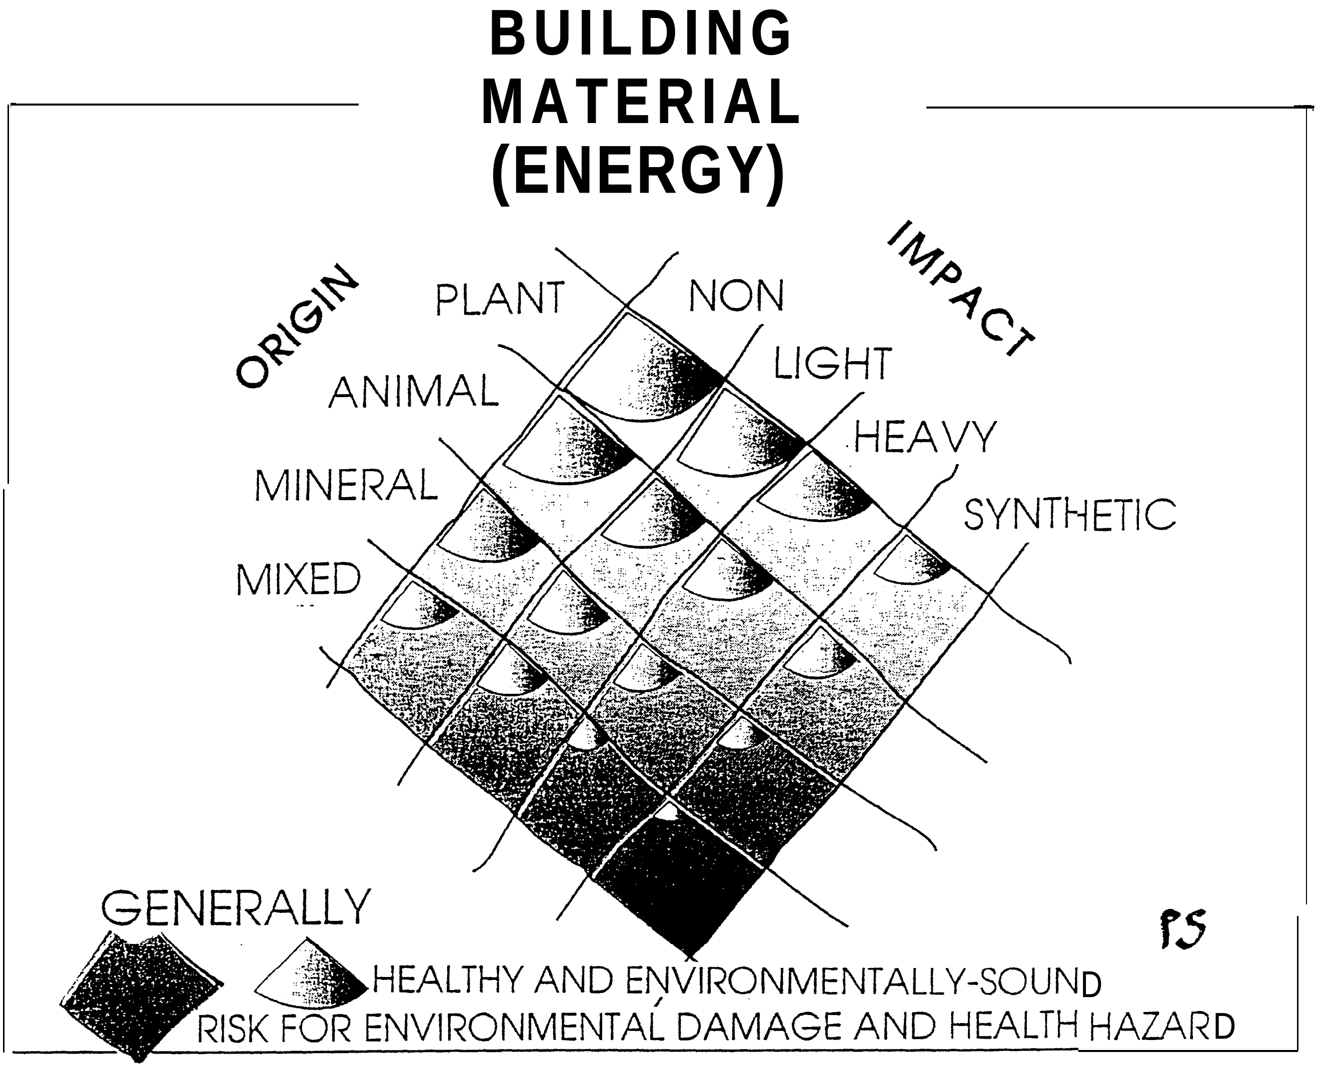

Figure 2
The evaluation of the impact of the use of materials (and energies) on health and environment is already roughly possible by the means of the Material and Energy Choice Material.

Since building is teamwork, always - except an hermit alone builds for himself - Conflict and Dispute Resolution is most important. The Method Holistic Participation - MHP - serves this purpose excellently and can be applied for problem solving of nearly each complex task, in which different, even opposing parties will participate. Based on very old experiences in pre-industrial societies, firstly again applied by Konrad Wachsmann and Walter Gropius in Building Technology in the fourties and further developed by the author, it is possible to use this method effectively in order to reach common solutions mainly by consultation and in consensus.

Figure 3
The Logo of the Method Holistic Participation symbolizing the rol play's of co-operating (expert) persons or teams, who in a weaving rotation - even starting with opposing opinions - can come to consensus.

Beside the importance of Legal and Procurement Practices and the Right for Environment it will at least be necessary to consider Management as a key to get the things done. The Indoor Climate as the reason wherefore we build and Materials and Technologies, which are strongly related to procurement problems, which are 'responsible' for the materialisation and realisation as well - have to be taken in consideration.

Together with a responsible view on those fields, it will be a 'conditio sine qua non', to handle the absolute principle of care-taking in legal and procurement practises, considering the whole of humankind in the radically smaller getting world.

Figure 4
Example(s) of Sustainable Building for various purposes illustrate the practical possibilities.

Planning techniques and environmental issues in procurement

A. Ciribini
Dipartimento di Ingegneria dei Sistemi Edilizi e Territoriali, Politecnico di Torino, Torino, Italy
G. Rigamonti
Dipartimento di Ingegneria dei Sistemi Edilizi e Territoriali, Politecnico di Milano, Milano, Italy

Abstract
The paper aims to explain how procurement methods for Public Works in Italy based upon severe networking planning techniques could improve quality, safety and environmental management,
Furthermore, environmental issues are related to refurbishment works, that are more and more increasing in the Western Countries.
Finally, effective procurement methods (construction management based) minimise environmental degradation especially when an integrated project plan is required by clients and owners.
Keywords: environmental management; project management; health and safety planning.

1. Resource planning and environmental management

Resource management is becoming the key issue in our research concerning project planning techniques for environmental and safety management in tendering and contracting into the construction industry.
Furthermore, refurbishment works, that are very often made in the inner cities and towns, the inhabitants living within buildings to be refurbished, are the most sensitive.
Our studies were, firstly, focusing on links and relationships amongst activities (already constrained by various parameters), because of the usefulness of lags and floats in ascertaining and diminishing environmental and safety risk factors and levels.
For instance, the need to reduce overlaps is well known, even if, for example, in refurbishment and rehabilitation works uncertainties are overwhelming the planned approach.
Nevertheless, the critical agents seem to be non financial resources (labour, plant, equipment, materials) rather than activities, the former being more timing and scheduling driving: in any case activities are carried out by resources.
For this reason, we are purporting that is advisable to plan the extremely large number of resources involved on even the smallest rehabilitation site in a deeper detail for the task of grouping.
For planners it could be a mistake to group all the resources into a single resource or, at the very worst, considering only the key one.
In other words, we have begun to establish resource-based models instead of the traditional activity-based ones, because of the accuracy more and more required in the advanced project planning practice.
Planners are continously trying to allocate only few, main resources (usually, no more than three) to each activity to monitor effectively cost and cash flows, but, from an environmental and safety risk management oriented viewpoint, critical resources could not be of necessity the most expensive ones or the scantiest ones.
Or, finally, the resources which are assigned to activities laying on the critical path could not be interesting to control closely.
Till now resource profiles and levels have been used chiefly for determining activity durations and resource-driving costs (excluding environmental and safety costs derived from a bad allocation of the available resources): above all, resource demand has been envisaged when levelling and smoothing was needed.
In so doing, planners are neglecting dangerous interfaces between resources and inhabitants or sites.
It is important therefore that due care is taken in selecting and assigning resources, knowing their productivity but also environmental and safety riskiness.
Human resources on sites (engineers, planners, quantity surveyors, quality managers, safety officers, skilled craftsmen, labourers, bricklayers, plasterers, and so on) have to be trained about environmental management.
Human resources, which are handling materials and driving plants and equipments can, indeed, interact each other causing safety problems.
Furthermore, same gangs could interact with the inhabitants (on refurbishment sites) and the environment causing environmental problems.
Meanwhile, we have performed an examination considering real, abstract and space resources, particularly on new factory building sites.
Lack of space, for instance, is often a dangerous restriction during the execution of an activity.
On construction projects, space, as a primary factor for storage, is limiting quasi-inconsistent operations which take place together.
Planners are going to define exactly space resources and spatial constraints for activities, operations, real resources.

Likewise, abstract resource management is needed to avoiding that two or more incompatible or dangerous activities (from the environmental and safety perspective) do not happen at the same time.
On the other hand, clients wishing to increase environmental and safety management must acknowledge proportionately, on the bid and award phases of the tendering, accrued costs carried out by contractors in reducing overlaps and interactions.
Planners find often difficult to develop a plan of works which consider every resource independently for various purposes: so, it is better to identify the environmental and safety most sensitive resources.
Moreover, key resources have to be analysed with regard to the assigned activities: to prevent likely risks we have to foresee the pattern of resources (single or multiple type) required by activities over its durations.
The variation of the resource level demanded by an activity is the main topic we have examined, together with the moving of the resources visiting different activities on the same place on the same day or week.
It is necessary, on sites, to plan and control a host of multiple variable resource demand activities to reduce risk levels.
We are recognizing, by measures kept on the field, that quantities of resource allocated to an activity is often far from to be constant: quite for the same type of work included in the activity considered, keeping into account uncertainty built in a project, when the activity duration is also variable.
Of course, managers and planners usually think that it is an unuseful waste to spend time and money in producing a more realistic and accurate resource demand model for the cost control purposes.
As a matter of fact, if a deal of activities in a plan of the works is encompassed, it is advisable to accept the constant resource demand from a statistical viewpoint, but concurrent environmental and safety key activities should not be managed ignoring variable trends.
When such a condition occurs, planners find convenient to split the large variable resource demand activity into a number of smallest constant or less variable demand sub-activities containing as less key resources as possible: to do it, they have to detail, or even change, method statements.
Consequently, resource-duration relationship seems to be very difficult to forecast and plan: for instance, changes in the size of gangs is frequently happening.
It must be remembered that firms involved in refurbishment projects are seldom large: unplanned stops of occuring activities push top managers to assign their involved key resource (the non storable ones, over all) to other activities, lessening the realism and the reliability of the plan.
The aim of reducing risk levels for environmental and safety aspects planning requires more adequately resource demand profiles on a project, but it is further endangered by the behaviour of subcontractors, which tend to plan their own work independently, ignoring the master resource plan and neglecting working rates of the other firms and gangs together with interact and overlap on the same place.

2. Environmental issues in the tendering and awarding methods

The client organisation plays a key role in environmental and safety management over the tendering and awarding stage, because it is able and, above all, must force bidders, tenderers (and, later, contractors) to plan effectively the works to be done, without exceeding all bounds to reduce project duration by means of the crashing technique.
Client organisation should select, at the pre-qualification stage, only building contractors complying with (or certified against) the widespread Standards IS0 9000 and 14000: bui it is not enough.

However we are testing some methods to evaluate and monitor - on the behalf of clients' representatives - resource plans provided by bidders at the tender stage.

Such methods could allow clients to award tenders to the higher environmental and safety oriented bid rather than to the lower cost effective one.

We are trying to establish a procedure to force bidders, on a contractual basis, to show links, relationships, lags, among purchasing, storing, handling and constructing activities: latest start and finish times of the activities are not adequate, in our opinion, to ensure environmental and safety risk reduction.

Bar and network charts have been organized in a different manner, easier understandable: it seems better to filter activities laying on charts by risk items, to group fragments of network according to different environmental and safety risk levels.

Furthermore, we aim to define site-related time-space charts (similar to time-chainage charts used on road works) to visualize activities carried out in the long run: from a spatial perspective.

Clients could support, through settling criteria of interim and final payment accounts, those contractors that are wishing to foresee in detail, before signing, resource consumption curves (linear and non-linear distributions), from a qualitative point of view, at least, together with all the splitting, stretching and crunching attempts made when planning.

Contractors (clerk of works) should be acquainted with non-linear and variable resource demand curves concerning activities laid on the network

Moreover, the client organisation, after signing the contract, should timely require the contractor to provide not only the site lay-out and the master plan of works, but also detailed fragnets (planned by specialist firms) and a resource bar chart encompassing the main real resources to be assigned to activities and place on site.

Finally, such a mandatory document as the health and safety plan (in the EC countries) could be enlarged to include the environmental issues.

Undoubtfully, construction management based procurement methods allow a closer project information exchange between clients and contractors about resource management.

Otherwise, the adverse relationship between counterparts built in traditional procurement paths, which are not at all waning in popularity, could lead to litigations about damages and casualties.

As resource management shows, a cooperative and consistent effort is absolutely needed to prevent such events.

The Direction of Policies and Systems for the Development of Sustainable Human Settlements in Korea

- Focussed on Multi-Family Housing Estates -

K. I. LEE
Housing Research Institute, Korea National Housing Corporation, Seoul, Korea
The Centre for Sustainable Construction, Building Research Establishment, Watford, UK

Abstract

As the Habitat Agenda was established at the Habitat II conference in 1996, the Korean goverment is planning to establish the Korean Habitat Agenda including policies and institutional systems which deliver development objectives that are compatable with the aims of sustainable development. Within this context, the aim of this paper is to establish the direction of policies and systems for the development of sustainable human settlements in Korea.

With this aim in purpose, this paper firstly extracts the indicators for sustainable human settlement from worldwide cases, and then surveys and assesses four representative housing estates in Korea with these. It then discusses the problems of achieving environmental sustainability in housing estates. Finally, this paper seeks to establish the developing direction of policies and systems for sustainable human settlements in Korea.The direction of policies and systems which are suggested are as follows.

To achieve sustainable land-use, a proper development density is proposed, while a conservation law for natural resources in residential development is also suggested. Secondly, for sustainable transportation, a development direction for an environmentally friendly transport system is advised to decrease both travelling distance and the need to use a private car, leading to a reduction in pollution.

Next, an energy saving layout control and a system using grey or rain water are promoted to save energy and water resources.

Finally, for the ecological environment, a legal instrument should be promoted to enable developers to introduce various kinds of biotops such as ponds, lakes, hills and so on. It could also provide for a green network as an ecological corridor within a housing estate and between housing estates and adjecent biotops. This has a very important role in both allowing animal movement and enhancing biodiversity in the development of sustainable human settlements.

Keywords: Sustainable human settlement, Habitat II, Indicator, Housing, Policy

1. Introduction

Nowadays, sustainable development has become a worldwide paradigm after the Bruntrant definition (World Commission on Environment and Development) : '... development that meets the needs of the present without compromising the ability of future generations to meet their own needs'.[1] Also in residential development, sustainable human settlement is an important issue. The Habitat Agenda and the Istanbul Declaration came out of the Habitat II conference in 1996. The Korean goverment is proposing to establish the Korean Habitat Agenda including policies and institutional systems which deliver development objectives that are compatible with the aims of sustainable development.

The aim of this paper is to establish the direction of policies and systems for the development of sustainable human settlements in Korea. For this purpose, the paper does:

Firstly, understand the concept of sustainable human settlements through literature reviews, especially focused on the Habitat Agenda declared at Habitat II in 1996. And secondly, extract the indicators for sustainable human settlement from worldwide cases to assess the sustainability of the human settlements in Korea. After that, survey and assess the representative housing estates in Korea with proper indicators and then discuss the problems of the environmental sustainability of the housing estates and the direction of residential developments. Finally, this paper aims to establish the developing direction of policies and systems for sustainable human settlements in Korea.

2. The concept of sustainable human settlement

In Habitat II, sustainable human settlement development ensures economic development, employment opportunities and social progress, in harmony with the environment. It incorporates the principles of the precautionary approach, pollution prevention, respect for the carrying capacity of ecosystems, and preservation of opportunities for future generations.[2] Therefore sustainable human settlements can make a substantial contribution toward achieving sustainable development in all countries.

Written this agenda, there are several categories to develop sustainable human settlements. These are sustainable land use; social unity through overcoming poverties and creating jobs; sustainable environment; sustainable energy-use; sustainable transportation and communication systems; and finally conservation and restoration of historical, cultural, and natural heritages.

Among the categories of Habitat II, this paper focusses on the four physical categories which are sustainable land use, transport, energy use, and environmental quality including pollution and natural ecology.

3. Extraction of the indicators for the assessment of sustainability

This study reviewed various kinds of literatures regarding the indicators for developing sustainable cities and human settlements, especially focussing on casestuding in the U.K., Seattle, Delft, and British Columbia.3 Among the indicators which were extracted from the above casestudies indicators were selected which are more relevant and can be easily measured in the Korean situation. The selected indicators are as follows.

Table 1. The indicators for assessment of the Korean housing estates

Classification	Issue	Indicator	Unit
Land use & Transport	Land use	*Household density *Conserved area	*units/ha *conserved area /total area
	Transport	*Commuting ratio on foot or by bicycle *Commuting ratio using public transport tools	• [illegible] •%
Environmental Quality	Air Quality	•the amount of SO_2 Emission *the amount of NO, Emission	• ppm/month • ppm/month
	Water Quality	• BOD *Distance from polluting origins (factory, cattle sheds, . ..)	• [illegible] • m
Energy	Energy Saving	*Ratio of south orientation of housing buildings	•%
	Renewable Energy	•Using ratio of solar energy	•%
	Water Economy	• Using ratio of greywater • Using ratio of rainfall	•% •%
Ecology	Water Friendly Space	*Distance from lakes, reserviors *Area of water friendly spaces	• m • m2/Person
	Greening , Spaces	*Area of green spaces *Distance from natural green spaces(forest, park, . . .)	• m2 • m
	Biotop	*Area of biotops *length of ecological corridor	• m2 • m
	Bio-diversity	• Bio-diversity of wild animal (birds, insects, fishes...) • Bio-diversity of plants	*species *species

4. **The survey results**

4.1 **Overview of the survey**

The aim of this survey was to assess the environmental situation and sustainability of Korean human settlements and draw out the problems. The scope of the survey covered the four categories, which are land use, transport, energy use, and natural resources as above. This survey focussed on 4 housing estates which are mainly multi-family housing estates in the new towns in Korea.

The examples were selected by residential density, the size of housing units, the building type(highrise or lowrise), the existence of a natural conservation area or not. They are representative of the types of multi-family housing estates in Korea.

Table 2. The overview of the sample housing estates

Case	Compl -etion	Size of land(m^2)	Number of units	unit/ha	Volume Ratio	Number of stories	Size of units(m^2)
Gwachon lowrise	1984	107,432	1,122	104.4	72.83	3-5	53-90
Bundang highrise	1991	122,588	1,781	145.2	227.0	5-28	66-23 1
Bundang lowrise	1995	17,205	240	139.4	158.3	4	66
Jungdong highrise	1993	36,926	1,008	272.9	228.0	14-25	57-105

4.2 The results of analysis

4.2.1 Land use

1. Residential density
In the above table, we can see the residential density is too high to achieve environmental quality compared to the exemplars in Australia(Table 7). In recent highrise residential developments, the volume ratios of most housing estates are over 200% while the household ratios are over 200units/ha. This results in overcrowded conditions and in lessening green spaces as well as introducing increased pollution and waste.

2. Conservation of natural resources
There is no strong legal or institutional system to prevent developers from destroying natural resources such as hills, forests, lakes, streams and so on. Therefore, it is very rare to conserve these in residential developments in Korea because the development density is too high. Moreover, in the development process, natural biotops such as, hills, forests, streams and so on, are almost always destroyed. The Gwachon newtown was a special case which preserved the natural resources because the Korean government had a special goal which was to develop it as a garden city while keeping the existing green spaces.

Table 3. Conservation ratio of natural resources

Case	Area of the conservation (m^2)	Conservation ratio(%)
Gwachon lowrise	15,610	14.53
Bundang highrise	0	0
Bundang lowrise	0	0
Jungdong highrise	0	0

4.2.2 Transportation

1. The commuting tools
Table4 shows that 54.6% of the residents use their car for commuting, while less than 10% of residents walk or use a bicycle. Among the four housing estates, the Gwachon shows the highest percentage use of public transport. This is because the residents in the Gwacheon newtown are situated close to use the subway. It is relatively small compared to the other estates, so most residents live near the subway.
The Bundang newtown also has a subway penetrating the newtown, but the size of the newtown makes access to the subway difficult for some residents. A higher percentage of people at the Bundang highrise use public transport as the subway is located relatively nearby, compared with the lowrise estate which is located at a greater distance from such resource.
Although the residents of Jungdong newtown are of relatively low income, they have the highest ratio of private car use because there is no subway available.

Table 4. The commuting tools (unit: %)

Case	walking/bicycling	public transport	private car
Gwachon lowrise	6	56	38
Bundang highrise	86 .	35.5	55.9
Bundang lowrise	8 8	30.8	60.4
Jungdong highrise	10 . 5	23.3	66.3
Total	8.4	37.0	54.6

4.2.3 Pollution

1. Air pollution
All the housing estates in our survey showed evidence of being over the environmental standard in SO_2, NO_2 especially during the winter season. Recently, there were several ozone warnings in residential areas of Seoul.

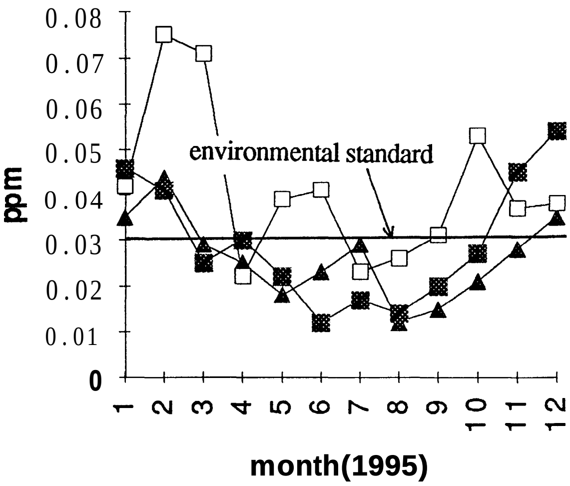

Fig 1. SO_2 emission

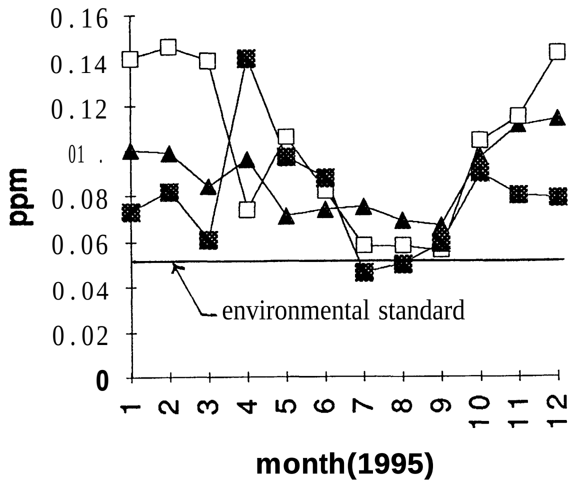

Fig 2. NO_2 emission

2. Water pollution
The BOD(Biochemical Oxygen Demand ;mg/l) in residential area are almost over 10, while the maximum is 35. This is a potentially harmful condition to aauatic animals and plants.

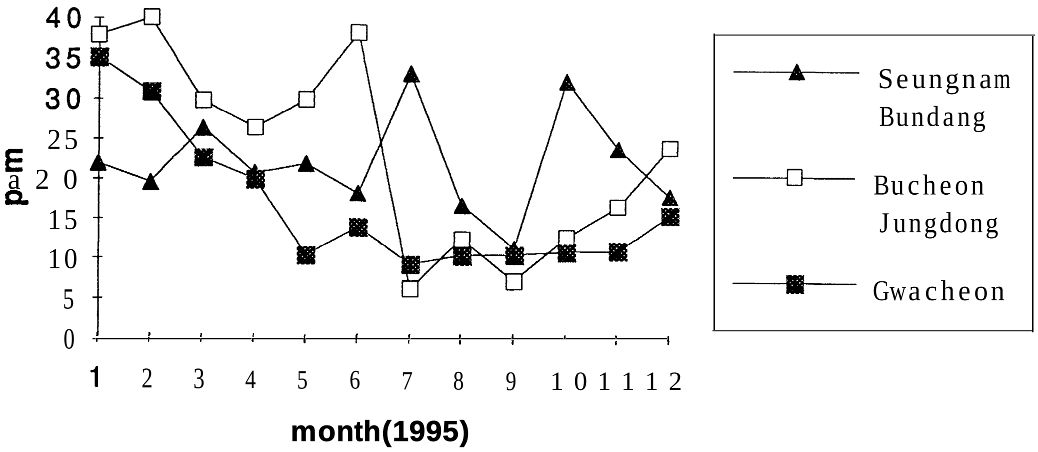

Fig 3. The BOD of the samples in the neighbouring river and stream

4.2.4 Energy saving
The orientation of housing is very important to residents because it is very cold during the winter season in Korea. But nowadays, due to higher development density the designer has to position buildings facing both east and west as well as south. There are a

few housing estates which try to conserve water by making use of grey or rain water but these are scarce.

Table 5. the ratio of building orientations (unit:%)

Case	south	south-east	south-west	east and west
Gwachon lowrise	38	21	20	21
Bundang highrise	0	**34**	**63**	**0**
Bundang low-rise	**73**	**0**	**0**	**27**
Jungdong highrise	50	0	0	**50**

4.3 Assessment of the ecological situation

The method used for this assessment is the Cross-Sectional Method.4 Meanwhile, the absolute numerical values of the measurements were standardized to make comparative analysis possible. The equation of the standardization is as follows.

- $Zi(Z\text{-}score) = \frac{Xi-X}{sx}$ (Mean=l, Dispersion=l)

Zi : Standardized score of i
Xi : Size of X

Table 6. The standardized results of the ecology survey

		Bundang highrise	Bundang lowrise	Gwachon lowrise	Jungdong highrise
Distance to water biotop		56.57	76	75.45	25.85
Area of water biotop		0	0	0	0
Distance to natural green		59.64	56.07	64.99	0.75
Distance to park		13.5	73.5	63.25	17.25
Ratio of green space		24.77	56.75	91.32	22.77
Ratio of natural conservation area		**0**	**0**	42.66	0
Biodiversity	Birds	0	23.28	92.77	23.28
	Insects	40.64	12.54	85.1	43
	Amphibia	0	0	94.4	0
	Fishers	45.9	61.07	76.58	0

Among the four housing estates, the Gwacheon lowrise shows the highest biodiversity because there is a large conservation area including forests, hills as well as the largest green spaces. Moreover, there are green footpaths which act as good ecological corridors and are connected with the adjacent forests and streams, and enable wild animals to move freely.
Meanwhile, the outdoor conditions were geneally so dry, due to the lack of water features such as ponds and streams, that very few animals survived.

5. Dicussion

5.1 Land use

Residential density is important in sustainable human settlements because it affects the equilibrium between development and environment. The density of Korean multi-family

4. This method is focussed on the special time. The assessment was done From June 15 to July 30 with Environmental Ecology Research Lab. in Seoul National University.

housing estates is too high to achieve sustainable environments. Therefore, it is important to find a proper density of residential developments for sustainable human settlements.

Table 7. Residential densities of sustainable housing development projects in Australia and Korean cases

Density (units/ha)	15	25-50	100	250	500
Development Cases	*Australian detached houses	•Mawson lake sustainable development (Australia)	• Halifax ecocity (Australia) • Gwacheon lowrise	• Jungdong highrise	•Public highrise housing in Korea

In the above table, the residential density of the Halifax ecocity is very similar to the Gwacheon lowrise which is most preferable among the Korean housing estates surveyed. It means that the Gwacheon has a social sustainability as well as an environmental sustainability. Of course, economic sustainability is very important in a residential development, but the Halifax ecocity project has over 210% volume ratio which is similar to the density of recent developments in Korea. Hence, 100units/ha seems to be the sustainable density in Korean multi-family housing development.
Next, a natural conservation area is the core element for ecological environments and enables plants and animals to flourish. The Gwacheon lowrise, which is a rare example of an estate with a large conservation area, has shown a higher degree of biodiversity in this survey.

5.2 Transportation system

The main commuting method in Korea is private cars which emit various pollutants while costing a lot in energy, money, and time. Catering for this kind of transportation system means that roads in the newtowns of Korea are very wide for the convenience of car traffic while walking and cycling are usually unsafe and uncomfortable. This system is unsustainable for the future because it contributes to global warming, air pollution as well as the depletion of fossil fuels in several decades.
Therefore, an environmentally friendly transportation system which is focussed on public transport in connection with shuttles, cycling and walking, should be introduced in residential developments. Also, an integrated land use and transport planning policy should be encouraged at the town planning stage. For example, high-density housing must be located around a central area to heighten accessibility, reducing both travelling distance and the need to use a car or transport in general.

5.3 Energy

In the traditional housing layout, the layout to the south was a key design element in Korea. But nowadays it is very difficult to keep south facing orientation because of block-type layout, which can raise development density, was -become very general in Korea recently. Moreover, there is no legal or institutional system to measure and enforce proper daylight standards. Therefore, the possibility that there are housing units without any direct sunlight ,especially in the winter season is very high
Solar radiation is a infinite and renewable source of energy which can be easily obtained at a cost. Hence, in housing planning, use of solar energy should be encouraged by a legal or institutional system.
Moreover, a system using grey or rain water should be promoted to save water resources.

5.4 Natural Resources

At first, the critical problem is that it is too dry because there is no surface water resourses in the housing estates. Therefore, the survival of animals is very difficult while amenity and comfort is very low. So, it is essential to conserve existing streams, lakes, reservoirs, and ponds, while collecting water and creating water biotops is important.

Another issue is to establish a water economy system, namely, a system that uses grey water and rain water. For this aim, water tanks and reservoirs can be considered as a tool both to conserve water and make a water biotop.

Meanwhile, the next important issue is to preserve features such as forests, hills, and wet areas, which form the core for ecological habitats in residential developments. Conserving existing green areas is critical to maintain the previous ecological condition. Therefore, an institutional system should be introduced to keep the natural biotops.

Moreover, a green network as an ecological corridor in a housing estate and between housing estates and adjacent biotop has a very important role in enablinging animals to move and so to enhance biodiversity.

Finally, the biodiversity of the housing estates was very low because biotops, which enable the survival of plants and animals, were very few and very little. Hence, a variety of biotops should be introduced by a legal or institutional system.

6. Conclusion

As a result of the above research, a direction is proposed for policies and institutional systems leading to the development of more sustainable human settlements.

They are the density guideline which this research suggests at 100 housing units/ha to maintain the environmental sustainability; a conservation law for natural resources in residential developments; an environmentally friendly transport system which includes a public transport system and cycle-routes; a proper daylight standard; a legal instrument which enables developers to introduce various kinds of biotops, ecological corridors, and a green network.

Next, a comprehensive planning policy including land-use, transportation, and energy use should be introduced to reduce the demand for transport, to save energy by carefully considered layout and orientation, and to preserve natural resources through the planning process. For example, high-density residential developments in central areas and also housing around places of work outside the central area can be encouraged to decrease the need for the use of a private car.

Finally, higher pricing of fresh water is important to introduce a system which uses grey and rain water in housing estates. Also, the government can adopt a policy giving priority to residents who wish to live near their places of work.

Procurement and sustainability in construction industry:
Tendering for durable relationships with process and projects

W.Tij huis
Department of Construction Technology and Construction Process, Faculty of Technology and Management, University of Twente, Enschede, The Netherlands

Abstract
In the present construction industry clients increasingly seek for real value-for-money. This results in a stronger competition between contractors, preparing their bids for projects, e.g. by tendering-procedures. In addition to that effect, several governments are highlighting the issue of sustainability in their building-regulations. That means in much cases a stronger need for efforts on using sustainable building materials and systems. However, these issues seem to result in higher construction costs, which may be ineffective for the competition in the building market.
But is the need for sustainability really a cause for increasing building costs? For the short term it may be so, but for the long term these developments may even result in a more effective and efficient way of designing, preparing and realizing building projects. And not only for these aspects, but also for the periods of use and re-use of the building, these efforts can be useful: The client gets a building which is more sustainable. That means in particular that the building inhabits more durability "to survive" the period of use and even re-use, and it gives less risks for influencing its environment and inhabitants negatively.
This paper analyses some of the mentioned aspects about sustainability, especially with regard to the role of governmental regulations and the relationship between clients, contractors and architects. Recommendations are made for how these aspects could and/or should influence the procurement of construction-processes at one hand, resulting in realistic lower construction-costs at the other hand.
Keywords: architects, clients, construction process, contractors, governments, regulations, relationships, sustainability.

1 Introduction

Looking at the construction process nowadays, one can imagine that the activities generally used are being divided into different more or less sequential phases. Independent of the way of organising the construction process these phases can be distinguished into the following list [SBR, 1992]:

(1) Initiative;
(2) Design;
(3) Elaboration;
(4) Realisation;

And in addition to them, regarding e.g. long-term scope and building life-cycle:

(5) Use and/or Re-use.

Of course there can be some differences into the ways of defining these phases, but in general these are accepted parts. In addition to the mentioned construction process, there are several developments, which are influencing the way of working. A few categories with a some of these influences are e.g.:

(a) Procurement:
- *Integration of designing and construction activities;*
- *Partnering/Alliancing;*

(b) Involved parties:
- *Claiming attitude of clients;*
- *Increasing role of (small) sub-contractors;*

(c) Process environment:
- *Changing role and contents of building regulations/ codes;*
- *Need for lowest price for best quality (still in this sequence).*

These influences are in most cases the result of an important goal from much clients: Lowering prices, and improving quality. Thus, more emphasis on efficiency and productivity is necessary then. In addition to the aspects mentioned above, there can be seen another actual important development in the construction industry: The need for more sustainability into the whole construction process. And this need is not specifically initiated by the private clients of the construction industry, but in much cases by the governmental institutions (although also they are clients, when they procure building-projects, etc.); these demands are national and international translated into regulations, building codes etc. Just like the building procedures they differ e.g. throughout Europe and also more globally [Cooke and Walker, 1994].

Even neighbour-countries like France, Germany, Italy, United Kingdom and The Netherlands do have large differences according technical and organisational aspects in construction industry [Bollmann et Vincent, 1993; Garaventa e Pirovano, 1994; Tij huis, 1996; 1997a]. The existence of (multi)cultural differences play an important role in these aspects [Sanders en Neuijen, 1987].

The situation mentioned above results in the fact that especially the private clients in the market cannot influence effectively these changing and adaptation of regulations; not on an international scale but even also not on a national scale. And e.g. contractors and architects also can't do it in a strong way.
Thus, rising the construction costs, resulting in a higher construction price for clients, seems a logical reaction, but may not be the real solution for the future way of incorporating sustainability into construction projects. Especially not when regarding to the need for lowering prices into competition and improving quality. But what to do then when these stronger need for sustainability really rises the construction costs nowadays?

2 Rising demands for sustainability: Some viewpoints

2.1 General

Taking into account the developments for stronger incorporating sustainability into construction industry, it is interesting to see how the main parties involved in the construction process are dealing with it. In the following part some viewpoints are being described according practice and recent literature, for especially the following distinguished main parties in the construction process:

(1) government;
(2) client;
(3) architect;
(4) (sub) contractor.

It is a more or less generalized way of looking, but it tries to give a brief sort of state-of-the-art viewpoint from parties involved to the subject of sustainability in the construction process within construction projects. This may lead to discussion and/or rethinking the aspect of sustainability in procurement and construction industry.

2.2 A governmental viewpoint

When introducing sustainability-needs in the national building regulations ("Bouwbesluit") it was of course not the goal to rise the construction costs. At least not in the long-term periods of the building life-cycle. And that is an important point to look at: When introducing sustainability needs it has and/or should have especially a long-term scope.

Some examples are e.g.: Introducing highly-efficient heating systems are quite expensive when installing them, but the optimization in the use of produced heat results in the reduction of the use of liquid natural gas over a long period; the use of European timber wood reduces the use of tropical timber wood, which reduces the damage to specific threatened ecosystems; etc.
In general, direct damage to ecosystems and landscapes are often one of the most important threats to our environment. Therefore the Dutch Ministry of Housing, Regional Development and the Environment sees (the lack of) biodiversity and space as an important core of the problems surrounding sustainability in especially a long-term period [Boer De, 1995].
The above remarks also imply, that implementing sustainability in building regulations should not only be reduced to one or some countries, but should become a general policy for all countries, as worldwide as possible.
This is meant not only for the fact that e.g. "polluted air is blowing around the world across national borders", but also that it makes it easier to export and import several building products, which may be used everywere according their sustainability aspects. But regional and (inter)national economic reasons will still play important roles in these cases.

2.3 A clients' viewpoint

When a building is being designed, planned and realized, a client may expect that the professional partners in the construction industry will take care of a certain way of using sustainable products, working methods, etc. But when it immediately means higher construction costs, they may think it unnecessary to incorporate sustainability in their projects. At least this seems the case when the client has a short-term scope; and many clients seem to have such a scope. This means that it is quite difficult to stimulate clients for demanding sustainability in their projects, when it costs them money.
An effective way is in much situations the economic approach: Give the clients a certain way of subsidizing, when they invest in sustainable items. Especially for highly sophisticated products which are not specifically general demands according the present building regulations (e.g. solar and wind energy, etc.) this can be a serious stimulus. For some more general techniques (e.g. improved insulation, etc.) this won't be really necessary, while the market prices are lowering for these products, resulting into lowering construction costs.

From the examples described above, an important point can be derived: When not introducing generalized upgraded building regulations according sustainability, the "market" for them will stay quite weak, while nearly none of the clients is asking for it; this results in quite high costs. Therefore, stimulation of new sustanability-techniques and products, e.g. by introducing (partly) subsidized programmes, can be an effective means for integration in construction-products and projects.

These stimulating subsidized programmes have to be scaled down when the "market" becomes big enough, resulting in increasing competition and lowering construction costs and prices.
Another option is e.g. the use of incentives [Peeters, 1993]. That can also be a way of stimulating sustainability in construction projects; e.g. when results/performances are according the defined wishes/specifications, a sum is being paid back by the client to the (sub)contractor. But, as **De** Boer describes it, it still stays important in most situations that the client "holds the bridles" when initiating a building project [Boer De, 1997].
In addition to that: Governmental organizations are important clients in the construction market, so they will also still try to keep some hold of the construction process. Maybe that "having interests on both sides of the table" could be one of the important reasons why "deregulation" seems to be a difficult development in the construction industry.

2.4 An architects' viewpoint

When preparing the design of the construction project, it is necessary to use an actual list of demands. Thus, the client must seriously know what he or she wants. But sometimes clients can not really describe their wishes clearly, but only have some more or less "vague expectations". Especially then the architect plays an important role: He has to translate these expectations into a list of specifications, leading to a "constructable"design. At least, it has to be according the building regulations, while he has the duty to add his experience and expertise into the specifications and design. Doing so, the architect (or the "designing discipline", as e.g. a member of a contractor's design and build team) is one of the first parties in the construction process, who can add sustainability in a construction project. And that opportunity they will be using increasingly.
In the Netherlands e.g. there have been procured recently officially specific experimental projects, in which certain more or less sophisticated sustainable aspects are incorporated. Some features like specific installations and materials are e.g.: Solar heating, rainwater-toilets, re-used concrete and brick aggregate, etc.

It may be clear that the role of the designing architect will be an important one regarding to the used specifications etc. in the field of incorporated sustainability. On the other hand, one has to be realistic, and not only focus on "alternative ways" of design-concepts. Also in quite "normalized" ways of recent design concepts there can be a highly degree of sustainability, e.g. : certain sustainable concepts like reusable building components, *'low energy consumption" production processes, etc.
Thus, combining these features and activities, the result can be a cost-efficient building project, looking within the long-term scope. Although the initial costs may be some higher in the present, caused by sustainability-efforts (like e.g. extra costs in the Netherlands for preparing the "Energy Performance" -EPN- calculations [BNA, 1997]), the costs of use (e.g. energy-consumption) and re-use can be lowered then in the near future. When looking to costs for sustainability with regard to the influence of the building to its environment, methods like life-cycle analysis (LCA) are quite widely used.

But as Beetstra described, a broad environmental assessment of buildings is not possible with LCA, at least for the time being [Beetstra, 1996]. At least in addition to the above aspects, as it is in much cases: For a good building project you need besides a list of specifications, good design and efficient building activities also and especially: Good clients; people with a (long-term) scope and viewpoint.

2.5 A (sub)contractors' viewpoint

The implementation of sustainability in construction process not only influences the use of products, but also the working methods in the process. As a recent article describes it, the rising of sustainability (resulting in e.g. upgraded environmental regulations) is an important reason for rising the construction costs and prices. Especially in the case of using construction equipment (maintenance, fuel, specifications) this means e.g. in the region Amsterdam in 1998 an expected increase of circa 6 percent since 1997 of the costs for only the building-site. Added to the rising of the engineering costs etc. (an expected increase of circa 3,3 percent) this results in an expected increase of the total construction costs with circa 2,1 percent for 1998 [Cobouw, 1997a]. And e.g. especially in (in-town) areas where there has to be demolished before starting new construction projects, the costs will rise quite high: Demolished material cannot be “simply thrown away”, but has to be re-used or to be cleaned, etc. As e.g. suppliers already have initiatives for recycling their products after removing/demolishing them from the used building projects. The recycling initiative for polystyrene building products like insulation is an example for this, resulting in e.g. new polystyrene building products [Cobouw, 1997b].

For contractors this means not only looking to their clients and markets, but also and especially to seek for their core-competence [Huovinen, 1996]. The emphasis in competition is especially on (the performance of) the “end-product”. This means that delivered performances during use and/or re-use of the building projects are getting most important. Combining this with the emphasis on e.g. Build-Transfer-Maintenance (BTM), the long-term scope will become of increasing importance [Tijhuis, 1997b]. This should include the use and re-use of the building (and in addition to that e.g. demolished building materials, etc.). Yet, nowadays it will not really be succesful without incorporating sustainability. So it is a real challenge to incorporate it into projects.

3 Conclusions and recommendations

When only looking to sustainability as a the cause for rising construction costs and prices, it will not really become a general accepted way of working.
Like already can be seen in practice, it is possible to incoporate it into construction projects when there is a right stimulus for using it. This stimulus can be e.g. an “immediate incentive”, like subsidizing for clients. Yet, this will not be a real solution, while these incentives should only be used to stimulate the “market” in the beginning.

Decreasing incentives should be compensated with really lowering construction costs. As e.g. a regional governmental client recently investigated the possibility of long-term relationships with groups of contractors for realizing their building-projects: Working within a more or less standardized concept (a so called "bouwstroom") could then reduce the overall construction costs including maintenance, within the demanded quality-level [Provincie Zuid Holland, 1997]. Already in the early sixties this way of working was being used quite regularly, although nowadays there should be much more effort in keeping the individual quality as high as possible. Long-term "flexibility and maintainability" for keeping the projects upgraded for the market and sustainable for its environment are important issues then. A strongly collaborative organization will be necessary then for being succesful in these fields.
These viewpoints can give a good stimulation for integrating sustainability in projects, but still very important will be that the client must accept it; not only now, but also in the near future. A good concept and seriously attention to the project life-cycle can stimulate this. Working on durable relationships within construction teams should then be a logical part of the process. The creation of e.g. alliances could then be an effective way of offering cost-efficient solutions to clients [Badger and Mulligan, 1995]. But the use of integrated product-process concepts plays an important role then [Tijhuis, 1997c]. This can rise the efficiency of the work, and gives clients a clear focus on the "added value" for their projects. Sustainability can be and should be such a value.

Land planning evaluation: The new Tuscan Planning Act N. 5/1995

V. Bentivegna
Dipartimento di Processi e Metodi per l'edilizia, University of Florence (Italy), adviser of the Regional Government of Tuscany

Abstract
This paper examines the new land planning act of Tuscany which can be considered one of the most innovating planning act. For instance, it states that the whole land planning activity carried out in the region must pursue the leading goal of the sustainable development. The paper focuses on one of this innovating aspect, namely the evaluation of the choice made in the plan and describes the structure of evaluation system established by the Tuscan legislator both under the organisation aspect and the contents of evaluations.
After three years of validity it is possible to make some remarks on the performance of this evaluation system, which is not highly satisfying, because of the inefficient behaviour both of the bodies charged of it application and professionals
Keywords: environment, evaluation, land planning planning law

1 Introduction

Evaluation is rather an unusual activity in land planning, but the growing interest in environmental issues is stimulating its use.
Most of the experiences in land plans evaluation concern structural plans at the various levels and sectorial plans, but there is no great experience in the evaluation of town master plans. In fact, in this field there are very few reliable records, technical and professional skill is not widespread and, above all, local administrative and technical staff have no familiarity with this kind of problems.
Therefore, the new regional planning act of Tuscany can be considered an interesting occasion to see how evaluation can be taken into consideration in plan-making and to highlight some problem in its management

2 The Tuscan planning act n. 5/1995

The Tuscan Regional Act n. 5/1 995 "Rules for Land Management" [1] is the tool by which the Tuscany Regional Government intends ta govern the regional territory in the next future.
Because of its innovating contents, this law has become one of the most important reference for many Italian regions and for the most interesting bill of the land planning reform at national scale [2].
This law is based on these innovating principles:

- Sustainable development as the main strategic goal to be pursued by all land plans in the region. Sustainable development is defined by the law as " the development which assures equal potentiality of increasing welfare for all citizens and safeguard the rights of next generations in using land resources." Natural resources i.e. air, water, soil fauna and flora), towns and settlements, landscape, historical sites and buildings, technological and infrastructural systems constitute the land resources. Previously, land plans followed vague principles of efficiency, effectiveness and equity.
- The autonomy of all the bodies who have the right to plan the regional territory. The functional planning system is now organised in three levels:
    - the Regional Government establishes the medium and long run strategies and the general rules of planning in the regional plan (Piano d'Indirizzo Territoriale),
    - the Provinces specify these strategies and rules at their intermediate level and co-ordinate the local plans with the province plan (Piano di Coordinamento Territoriale)
    - the Municipalities apply these strategies in their master plan (Piano Regolatore Generale)

  Within this planning system, each body approves his own plan, just with the constraint of the compatibility with other plans

Previously, planning was organised according a hierarchical structure and land plans proposed by Municipalities and Provinces were approved by the Regional Parliament.

- A transparent decision process as a fundamental condition for correct planning. Social participation is essential in guiding and controlling the planning process, because of the lack of any substantial control. The transparency of the planning process is a major way to create a common knowledge. Previously, there was no interest for this issue.
- The town master plan is structured into three different but strictly co-ordinated planning tools, each of them having its specific and functional role:
    - the structure plan: which establishes the strategic issues of the municipality
    - the urban code, which governs routinaire issues
    - the integrated program of intervention which governs structural issues

  Previously, a single plan governed strategic, structural and routinaire issues.
- The compulsory evaluation of the plan. Previously, evaluation was not taken into consideration in land planning.

3 The need of evaluation

The use of the evaluation as a component of the planning process derives from these considerations [3]:

1. efficiency and effectiveness of planning choices in terms of sustainable development must be verified and demonstrated because urban planning does not include the judgement rules which allow the plan to be judged according environmental issues(a land plan can be considered a good one even if it is environmentally bad). Therefore, the planning process needs evaluation because it is not possible to judge the quality of the land plan when land resources are a major issue of the plan.
2. with the previous regional planning regulations, which followed the national ones, provinces and municipalities land plans ought to be approved by the Regional Parliament as the powers organisation in land planning were based on a centralised structure of authority. So doing, the upper rank of the hierarchy guaranteed that general interest were pursued by the plan and that its technical quality was satisfying. With the new law each body approves its own plan, without any hierarchical control. The structure of authority then becomes decentralised. In this new situation, provinces and municipalities become autonomous centres of responsibility and decision within the legal frame established once for all by the law. With the lack of external or internal regulators (the market and the hierarchical control), there is the need to demonstrate that land plans are efficient, effective and coherent with the main goal of the sustainable development. In other words, evaluation is an offset for the self-government.

3. a socially shared common knowledge of the planning process is essential for the effective social participation. Transparency, that is pubic knowledge of the planning process , must be assured.

4 Some notes on the evaluation of plans

In planning, evaluation is mainly seen as a decision aid, its aim is to identify the best or the most satisfying alternatives using formalised methods and procedures' The importance of evaluation as a decision aid in planning for sustainable development derives from the lack of self-control within the social system with regards to the environment, together with the complexity of environmental problems, which cannot be governed through the traditional bureaucratic-administrative model of choices. Therefore choices must be evaluated [4]

As planning decisions are the result of a social calculus, in which political feasibility, technical rationality and economic considerations are mixed, the plan evaluation appears as a political event, which is a component of the political context of the decision and it enters in the negotiation game associated with these public decisions. From this point of view, the evaluation plays a complex role fulfilling three practical needs for the public administration.

The first is a material one and consists in a better management of land policies and actions through the control of their effects on the environment? on the territory and on the social system. The second has a symbolic nature and consists in giving an image of rationality to administrative behaviour, justifying its choices. The third is related to politics and concerns the support given by evaluation to the social participation.

If planning evaluation has such a political role, it must be reliable, make use of verifiable information, must be based on the scientific method and become common knowledge [5, 6,7].

5 The evaluation of the land plans according to the Tuscany Regional Act n. 5/1995

According to the TRA n.5/95, evaluation is a major activity in the planning process and indispensable for approving the plan. This rule is enforced by the articles 5 and 29 which establish that:

- the environmental effects, together with the effects on ail land resources produced by each planning choice must be analysed and evaluated
- no town expansion is allowed, if there is a possible alternative in renewal and infrastructures re-organisation. In any case, the use of new land must have positive effects on settlements rehabilitation and natural resources safeguard

---

[1] Evaluation is generally defined as a scientific method, which is useful to express a judgement on the results of a policy or on the effect of an action with reference to some value. It is based on rationality and its aim is to measure results or analyse effects. Therefore, it emphasises causes and actors.

- the effects of any structural choice, which have structural effects on environment, settlements and communities, must be also examined through economic and financial evaluations.

How and when these evaluations must be carried out and the procedures of the evaluation process are established by the regional evaluation code..

5.1 The evaluation system

The evaluation system laid down by the TRA 5/95 can be describe according its functional organisation and the contents of the evaluations.

5.1.1 The functional organisation of the evaluation system

The functional organisation of the evaluation system is structured on three levels

1. The regional government level, i.e. the level of the evaluation rules. At this level, the regional government:
    - establishes the general rules and the evaluation procedures which must be carried out in land planning making, fur instance, what choice must be evaluated, when and how evaluations must be performed, who must evaluate, etc.
    - collects, elaborates and places the information needed for evaluation,
    - monitors the evaluation activity of both provinces and municipalities, encourages the spreading of evaluation sensibility among planners and professionals, co-ordinates professional training in the field and sponsors research activity
    - verifies the correct enforcement of its regulations.
2. The provinces level, i.e. the level of the evaluation guidance. Through its plan? the province:
    - converts the general rules laid down by the regional government into operative rules suitable for its territory, establishes the criteria and parameters which must be used in plans evaluation and co-ordinates the evaluation activities of the municipalities,
    - builds up the operative information system of land resources, individuating their vulnerability and reproducibility.
3. The municipality level, i.e. the evaluation operative level:
    - each municipality evaluates the actions included in its master plan according to the general rules established by the regional government and specified by its province.

5.1.2 The contents of the evaluations

The actions included in the land plan must be evaluated, not the plan itself. These actions are evaluated in regards of the specific goals of the plan and in terms of effects on land resources. The provinces establish which actions must be evaluated and the kind of evaluation needed in each case

These evaluations concern:

- the effects of an action on natural resources (impact evaluation')
- the effects of an action on land resources (impact evaluation)
- the new urban use of agricultural land (evaluation among alternatives)
- the economic and financial efficiency of structural interventions (efficiency evaluation)

6 Problems and diffkulties.

After three years and with several land plans which have been approved, it is possible to make some remarks on the performance of this law.
In fact, its first results are not exciting? because:

- the regional government has not yet accomplished some very important tasks? like the approval of the evaluation code,
- the provinces have approved or are approving their plans, but in many cases the evaluation aspect has been just touched, most of the provincial information ystem are fragmentary or not suitable for reliable evaluations, just a minority of them has fixed good evaluation parameters and criteria.
- most of the municipalities which have approved their structural plans, have underestimated the evaluation aspects, following the same mistakes made by the provinces.

But even those plans which have performed satisfyingly their evaluation task show important problems because evaluation still remains a side issue in the planning process,and not a structural component as request by the regional legislator'.
The unsatisfying performance of the Tuscan evaluation system has many reasons:

1. the widespread unfamiliarity of the evaluation activity among administrators and planners, so that intuitive and poor evaluations are prevailing,
2. the deficiencies of the provinces in leading the evaluation activity among the municipalities an co-ordinating the evaluation system at the operative level
3. the slowness of the regional government in performed its leading tasks., so that the lack of the regional evaluation code has negatively effected the functionality of the system, the right political choice of gradually introducing evaluation in the planning process has been often ill interpreted by local planners as low interest for this issue: the administrative and technical structure is inadequate.
4.

[2] The aim of this impact evaluation is to clarify choices in regards to the goals of the plan and to verify the effects of choice in regards of the general strategy towards land resources. Therefore, it cannot be confused with the standard environmental impact evaluation. In fact. standard EIE must verify the compatibility of a project with an environment situation, considered satisfying, therefore it is related to projects, ii 'needs detailed information which are not disposable at the planning level. it is only generically goal-oriented and, above all, it is too expensive to be employed in all the choice made in the plan.
[3] See, for instance, the structural plan of Pisa, which is one the most correct application of the law.

This situation has some important implications, the most important of which concerns the use of evaluation in the planning process. In fact, evaluation has mostly been used as a mean to justify the choices already made in the plan, that is, the legitimisation role of the evaluation has been preferred in comparison with its main task as a decision aid. This misuse is creating conflicts between analysts, political decision-makers and planners, because, when the analyst evaluates an already made choice (that is, when his main task is nothing but the legitimacy of the plan) he acts as a final judge of political and technical choices. Therefore, evaluation can be seen as a constraint to the political and professional autonomy of the decision-maker. Then, there are the risks either of rejection and manipulation of the evaluation and of potential conflicts.
Potential conflicts are also originated by the structure of the evaluation system itself The problem is which aspects must prevailing in plan making, i.e. if the environmental aspects are more important then the social, economic and functional ones. This is a main latent problem in many land plans. Even if the regional legislator has given a clear definition of sustainable development which does not allow bias interpretation of the weight of environment in planning, nevertheless, when the evaluation system markedly privileges the environmental evaluations in comparison with the efficiencv anh effectiveness evaluations, there is a confused situation which stimulates potential conflicts between partisans of the environmentalist plan and partisans of the other interpretation, thus giving which has a bad image of evaluation in planning.
The last remark concerns the behaviour of the bureaucratic and professional structures. Here it appears a large tacit resistance to the enforcement of the evaluation in land planning that has two main causes. From one side, the enforcement of the law requires a deep change in the consolidated professional capacity, which needs intellectual and physical efforts. From the other side, the most of planners do not have the culture and the technical skill to manage the evaluation aspect of planning. Therefore, disinterest and fear to loose the control of the whole planning process are widespread, which have brought either to ignore the evaluation or to produce very poor evaluations.
Concluding, even if the TRA n.5/95 is a verv important step towards the use of evaluation in the planning process, there is still a long way to do before reaching the goal.

ALTERNATIVE DISPUTE RESOLUTION: THE QUEENSLAND BUILDING TRIBUNAL

0 D Wilson, R M Skitmore and P A Davies
School of Construction Management and Property
Queensland University of Technology
Brisbane Q4001
Australia

Abstract
In 1992, the Queensland Building Tribunal was established with the specific goal of obtaining quick, inexpensive and simple resolutions to building disputes by means of mediation and/or tribunal hearings instead of the more usual forms of arbitration or litigation. This paper describes research aimed at gauging the success of the Tribunal in achieving its goal.

Two postal questionnaire surveys were carried out, one being for those who had resolved their disputes through the mediation process and the other for those who had taken the matter to the Tribunal's hearing process for a ruling by determination. Out of 168 questionnaires despatched, a total of 61 completed forms were returned and analysed. The results are described under four headings (1) fairness and impartiality, (2) formality and expediency, (3) credibility and public awareness, and (4) commercial reality.

The majority of those surveyed thought the mediation process to be sufficiently impartial, expedient, informal and knowledgeable. In contrast, the hearing process, as expected, was perceived to be less expedient and more informal and intimidating. There are significant areas of concern over the absence of 'of right' legal representation and the reasons for settlement at the mediation stage. It is suggested that mediators receive some training or at least some guidelines are issued on the mediation process, that "duty lawyers" are made available for consultation with the parties, and that mediators may, with common consent, act as adjudicators when circumstances require.
Keywords: Arbitration, dispute resolution, mediation, Queensland Building Tribunal, questionnaire survey.

1 Introduction

The "Home Building Review", was established in 1990 by the Queensland Government in response to the failure of the Queensland Builders Registration Board to resolve matters relating to building disputes. One of the major recommendations was that "there is a need for a quick, inexpensive dispute resolution process with simple procedures [and that] for this purpose a domestic building tribunal should be established to resolve all the disputes between parties in the home building industry" [1]. This recommendation was realised the following year under the Queensland Building Services Authority Act with the establishment of the Queensland Building Tribunal, whose exclusive duty it is to hear and determine matters relating to domestic building disputes. Under the Act, the Queensland Building Tribunal may appoint a mediator or mediators to endeavour to achieve a negotiated settlement of a domestic building dispute and the Tribunal has opted to use mediation as a precedent wherever possible in the settlement of disputes.

The process is simple enough. Upon a domestic building dispute becoming evident, a party may make application to have the Tribunal hear the matter. The applicant must then deliver a copy of the application form to the respondent who, in turn must notify the Tribunal's Registrar and the applicant of his address for service of documents. The Tribunal then proceeds to arrange a mediation meeting between the parties and issues a notice of mediation to both the applicant and the respondent. The mediation is then conducted at which time both parties are brought together with a mediator to attempt to reconcile the parties and settle the dispute. If an agreement is reached, the mediator reports on the terms of such agreement or settlement to the Tribunal. The Tribunal may then make a determination in terms of the settlement, and may make consequential orders or directions on the basis of the mediator's report. Should no agreement be reached, the Tribunal directs that statements be filed by the parties and all other witnesses. The Tribunal then directs that a pre-hearing conference of directions hearing be held at which time the Tribunal inquires as to whether or not the parties have reconciled or would wish to rediscuss the matter with a mediator. If the parties advise that no reconciliation has occurred, the Tribunal allocates a date at which time the matter is heard and the dispute determined. A member conducts the hearing at the appointed date and, based on the evidence, makes a determination in respect of the dispute.

The width of the Tribunal's power is extraordinary and its duties similar to that of a court. In the exercise of its jurisdiction., the Tribunal may exercise any one or more of the following powers:

- order the payment of a monetary sum to be owing by one party to the other;
- award damages, including exemplary damages, and damages in the nature of interest;
- order restitution;
- avoid any unjust contractual term or otherwise vary a contract to avoid injustice;
- avoid a policy of insurance under the statutory insurance scheme;
- order rectification of defective or incomplete building work; and
- award costs.

Under this Tribunal system, the mediator has the protection and immunity of a member of the Tribunal. Evidence of anything said or done in the course of an attempt to settle a domestic building dispute is not admissible in any proceedings before the Tribunal or in related proceedings. If a dispute is settled, the mediator reports the terms of the settlement to the Tribunal and the Tribunal may make a determination in terms of a settlement, and make consequential orders or directions. There is however, under the Act, no clear definition of who may be a mediator, the process of mediation or of what mediators may do. The minimum qualifications of the mediator are not specified nor is the person identified with the authority to appoint mediators.

Perhaps the most controversial aspect of the system is that the use of arbitration is specifically excluded as a means of dispute resolution. In Australia, where such issues are high on the political agenda, the specific exclusion of one particular industry group is tantamount to unfair discrimination. The main problem is not that mediation is included but that arbitration is specifically excluded under section 61 of the Act [2]. The reasoning behind this rather dramatic measure is to be found in the Home Building Review Report, which condemned the then current practice of arbitration as (1) lacking impartiality, (2) being prohibitively costly in both money and time, and (3) abusive of procedures. The extent to which this statement is actually true is not known at this time.

2 Survey questionnaire

In order to measure the degree of 'success' of the Queensland Building Tribunal mediation system of dispute resolution, some kind of feedback from its participants is necessary. In other words, the perceptions of those parties who have actual experience of the Tribunal and its proceedings need to be studied. For this purpose, a survey questionnaire was undertaken.

The Tribunal was contacted and a total list of all applicants and respondents that had been through the system up to that time (1993) was provided to the researchers. As a result, a total of 200 potential respondents were identified. Of these, approximately 90 were contacted by telephone to gauge their initial response to being surveyed and their acknowledgment that they would complete and return a postal questionnaire.

Two questionnaires were developed - one for those respondents who had resolved their dispute through the mediation process and the other for those who had taken the matter to the Tribunal's hearing process for a ruling by determination. The questions contained in the questionnaire were aimed at establishing the level of support, or otherwise, for the Queensland Building Tribunal dispute resolution system. To keep the questionnaire simple and gain a maximum response, it was designed to be completed in no more than five minutes. This resulted in an instrument structured over two pages in a question and yes/no response answer style. The questionnaires also provided for general commentary if desired and were issued to the sample with a pre-stamped return envelopes. In the event, 168 questionnaires were issued in late June 1993. In all, 63 completed questionnaires were returned - 33 relating to the mediation process and 28 related to the hearing process.

3 Results

The questionnaire and its results are divided into four sections: (1) fairness and impartiality, (2) formality and expediency, (3) credibility and public awareness, and (4) commercial reality. These are presented below.

3.1 Fairness and impartiality

The basic component of any justice system must be that it is seen to be acting in a manner, which is fair and impartial in its operation and determination to both parties.

3.1.1 The mediation process

The basic principles of mediation as a process of dispute resolution are such that the mediator should not be able to be seen as anything but impartial, as the mediator's primary function is to get the parties talking, to direct or help them achieve a settlement by themselves, which the mediator will ratify through a statement or mediation agreement.
Discussions with a member of the Queensland Master Builder's Association noted comments raised by some builders that they had felt pressured during the mediation process in a way which they perceived to be more than simply leading.

Overall, 80% of responses (95% of applicants and 70% of respondents) thought the mediation process to be impartial. Similarly, 92% of applicants and 75% of respondents considered the mediation process to be informal. 38% indicated that they were adversely pressured by the mediator to resolve the dispute.

3.1.2 The hearing process

29% of responses believed the process not to be impartial and 40% did not believe the process to be a fair means of resolving disputes.

3.2 Formality and expediency

Action and speed in resolving building disputes are of crucial concern to all parties. Procrastination in finding agreements can cost both parties to a dispute in terms of finance, time and health. Furthermore, behavioural studies suggest that parties are more likely to resolve a dispute on neutral ground and in a comfortable, non-suppressive, atmosphere.

In terms of the mediation process, the time involved in getting the mediation started should be quite short as “the Tribunal appoints a mediator who will contact the parties to arrange a mutually convenient time and place for the mediation within 14 days” [3]. This time frame should adequately meet the expectations of the parties.

The average time from application up to hearing was four months. This would seem to compare favourably with the traditional court system, where the general perception is that a matter before the court may, and often will, take several years to be heard and resolved. Also, the formal Tribunal hearing premises are well appointed, they appear to be fresh and do not seem to have any feeling of a stuffy court setting. The two rooms involved do, however, still represent a feeling of authority with a member (judge) set to the front of the room behind a desk separated by a large space from the disputing parties and public seating at the rear.

Although parties may not have legal representation present at mediation or hearing, many disputants obtain advice or assistance in preparing their claims and responses. There have been some differences in opinion over the availability of legal representation., with the Home Building Review Report opining that legal representation should only be as of right in the matter concerning disciplinary procedures against licensed building contractors and subcontractors on the grounds that “most building disputes are not complex and do not involve questions of law . . . most are resolved upon tidings of fact of a very basic character” [1]. Cotterell, however, holds the opposite view in claiming that many disputes ". . . involve factual and legal questions” [1]. Whether or not the disputing parties should be entitled to legal representation ‘as of right’ is an issue yet to be determined. It is likely that applicants would be against legal representation due to the extra costs involved and the possibility of the representation strengthening the opposing case.

3.2.1 The mediation process

The responses indicate that the Tribunal’s mediation is meeting the expectations of customers and builder if not the groups, which represent them. As far as expediency is concerned, 95% of all the responses confirmed that the Tribunal processed disputes to their satisfaction.

3.2.2 The hearing process

38% of responses thought the Tribunal hearing process to be conducted in a formal manner. 30% of responses did not consider the Tribunal hearing to be conducted expeditiously, with the same proportion also not feeling comfortable with the surroundings in which the hearing was conducted. 23% of responses indicated feeling intimidated by the member. As expected, the respondents (100%) were more in favour of 'as of right' legal representation than applicants (12.5%).

3.3 Creditability and public awareness

In following the doctrine of natural justice, which holds that *no man shall be a judge in his own* court, it is not the practice of the Tribunal to appoint industry-based persons such as architects, engineers and builders as mediators. As a result, the majority of the Tribunal's mediators have a legal background. This naturally raises concerns over mediators' ability to quickly grasp the technical issues involved in building disputes. The Tribunal does, however, engage the use of Queensland Building Services inspectors, most of whom have a building trade or technical background, to act as mediators. The building inspectors have had no formal training in the conduct of mediation or social behavioural studies.

This situation brings into question the credibility of the Tribunal. Any institution or organisation's creditability and acceptance rests on the level of competence it demonstrates. One means of measuring the perceived creditability of the Tribunal is by gauging consumers' and builders' perception of the Tribunal's knowledge and understanding of the building industry.

A related issue is that of public awareness. One view is that the Tribunal's services should be advertised extensively so parties may realise that there is a relatively quick and cheap means of resolving disputes available. Another view is that, if the Tribunal were to actively advertise its existence, it might become inundated with frivolous disputes that are presently being resolved easily and congenially by builders and consumers. To date, the Tribunal has adopted a low-key approach and consumers and builders are likely to become aware of the Tribunal's existence only when a dispute that cannot be readily resolved by the parties becomes evident.

3.3.1 The mediation process

A large majority of responses (93%) considered an adequate knowledge of the building industry to be important while rather less (74%) thought that the mediator really had such knowledge, with 84% of responses believing the mediation process to have been an appropriate solution to their problems. 48% of responses were aware in advance of the Tribunal's mediation procedure.

3.3.2 The hearing process

64% of responses thought that the Tribunal did have adequate knowledge of the building industry. 77% thought the Tribunal hearing to be an appropriate method and 50% were aware in advance of the Tribunal's hearing procedure.

3.4 Commercial reality

The social trauma that occurs due to a proceeding before a court or tribunal is difficult to gauge as each individual approaches, and in turn is affected by, such circumstances differently. It is a fact, however, that some people will be left with a lasting emotional scar. This issue is of particular interest when considering the resolution of disputes by mediation, which offers an opportunity to settle with a minimum of time, cost and emotional expense.

Actual or expected delays in proceeding to a hearing force applicants and respondents to make decisions and agreements which they may not have made had an immediate determination been available. Such delays can be for a period of 3 months or more and the Tribunal will naturally reflect a feeling of injustice in respect of decisions, which are made by parties as a perceived imposition. On the other hand, attempting to avoid delays by pressuring premature agreements is hardly likely to be a satisfactory solution as it is justice that is being sought and not just a speedy conclusion.

Applicants and respondents views were quite different. 3 1% of applicants against 58% of respondents reached a mediation agreement because of feeling unable to handle proceeding to the hearing process. 3 1% of applicants against 67% of respondents reached a mediation agreement as a result of a commercial financial decision, ie. to avoid the costs of a hearing.

4 Discussion

One of the major findings reported here is the significant numbers claiming to have been adversely pressured by the mediator to resolve the dispute. This problem seems to originate from a lack of instruction on mediation and it would seem a set of guidelines issued by the Tribunal might help. Such guidelines should not hinder or limit the running of the Tribunal's mediation process and should not prejudice the Tribunal's role of acting independently of the individual parties involved.

That some of the responses thought the Tribunal not to be impartial is of some concern. However, it could be argued that the perception of justice on the part of the losing party would be tainted by the mere fact of the result. One way to attempt to overcome this perception is for the proceedings to be conducted in a clearer and more open manner. Another possible solution is to introduce a duty lawyer system to complement the Tribunal's services with junior lawyers providing an advisory service to both applicants and respondents on a casual basis. Such a system should be both cost effective to the Tribunal and beneficial to those parties using the proceeding through the Tribunal system.

That 23% of responses found the Tribunal to be intimidating is unfortunate but perhaps unavoidable as it is very much a part of all judicial systems to provide an air of authority, which can be intimidating to some people, especially those with no previous experience of court proceedings.

The many responses, particularly from those who had been respondents in disputes, believing that 'as of right' legal representation should be available is clearly a question of benefits and costs. Legal representation is not only expensive but does tend to extend the period of the proceedings, and the question of finance needs to be addressed if the parties are to be provided with free legal aid. Legal representation is allowable under the present system providing the member feels it justified, this option being available on a case by case basis. Alternatively, the duty lawyer system, mentioned above, may suffice in most cases.

The question of the technical knowledge of mediators is potentially very difficult to solve. Clearly the doctrine of natural justice must be regarded and yet, equally clearly, some degree of technical 'know-how' is necessary for building disputes in order that decision makers are sufficiently well informed. The first issue concerns bias and the second concerns reliability. To have the best of both worlds would seem to require at least a technical adviser to the mediator. In view of the survey results, in which approximately three-quarters of respondents felt the current situation to be adequate, there seems to be little cause for alarm as yet.

One of the main purposes of mediation is to progress disputes to a conclusion as quickly as possible. That many of the respondents are accepting a premature settlement because of the time, money and emotional risks involved in proceeding onwards, suggests that further improvements are necessary to the present system. One such improvement might be to allow the role of the mediator to be extended to adjudicator where both parties so agree. This could help in cases where there is a deadlock and no other prospects for a solution other than to continue into a lengthy and protracted hearing. Instead of the present practice of calling bluffs, a simple executive decision by the mediator should encourage the parties to act in the pursuit ofjustice rather than in avoidance of the risks involved in continuing.

5 Conclusions

The Queensland Building Tribunal was established in 1992 with the specific goal of obtaining quick, inexpensive and simple resolutions to domestic building disputes by means of mediation and/or tribunal hearing. This paper describes research aimed at gauging the success or otherwise of the Tribunal in achieving its goal.

The majority of those surveyed thought the mediation process to be sufficiently impartial, expedient, informal and knowledgeable. In contrast, the hearing process, as expected, was perceived to be less expedient and more informal and intimidating. There are significant areas of concern however over the absence of 'as of right' legal representation and the reasons for settlement at the mediation stage. It is suggested that mediators receive some training or at least some guidelines are issued on the mediation process, that "duty lawyers" are made available for consultation with the parties, and that mediators may, with common consent, act as adjudicators when circumstances require.

The results of this survey generally support the Queensland Building Tribunal's mediation process in achieving the timely settlement of building disputes. Subject to the reservations mentioned above, there seems to be no major barrier to the development of equivalent organisations and procedures in other parts of Australia or the world in general.

6 Acknowledgments

Appreciation and thanks are due to Theo Haralampou, Registrar of the Queensland Building Services Tribunal; Mike Walton, Contracts Manager, Queensland Master Builders Association; Warwick Temby, Chief Executive, Housing Industry Association Ltd; Roger Quick, Committee member, Australian Institute of Arbitrators (Queensland Chapter); Raelene Kelly; Ray Potts, Assistant General Manager (Corporate Services) Queensland Building Services Authority; and the staff of Sommer and Staff Constructions Pty Ltd, particularly Walter Sommer and Ronal Peel, Directors.

Contractual systems for construction refurbishment projects

I.G. Okorji and S.G. Naoum

School of Construction, South Bank University, 202 *Wandsworth Road, London, SW8 2JZ,* UK

Abstract

This paper is based on an on-going research at the South Bank University London, UK The aim of the research is to develop an artificial intelligence system for the selection of contractual arrangements for construction refurbishment projects. The paper argues that there is no substantial study in the area of procurement selection for refurbishment works. The legal framework of construction contracts is reviewed. The main characteristics of artificial intelligence used for procurement selection are highlighted. The paper then concludes that there is the need to develop an artificial intelligence system for procurement selection for refurbishment works. The benefits that could accrue from the development and application of an artificial intelligence in procurement selection are many including a dramatic improvement of efficiency in terms of the speed of reaching an informed decision, reliability of the expert advise as the system is built in with a robust expert knowledge and it provides a datum of knowledge distilled from acknowledged experts.

Keywords: construction contract, procurement selection, artificial intelligence, construction refurbishment.

1. Introduction.

The lack of guidance in the selection of contractual systems for construction refurbishment works is seen as an acute problem (Robinson 1990). Robinson (1990) also argued that "the standard form of contracts developed for new build applications have very little relevance to the complexities and diverse nature of works on exiting shells". Ferry and Brandon (1991) advised, that "the uncertainties of refurbishment work mean that it will be almost impossible, and certainly inadvisable, to undertake the (refurbishment) project on the basis of lump sum competitive tenders for works, and other more collaborative methods of procurements will have to be used - either cost-plus or some form of management contracting" (Ferry and Brandon 1991). Fellows et al. (1985) in their research report observed that while contractual arrangements and management systems designed for new-builds are used for refurbishment work, "ad hoc use of new build arrangements does not satisfy clients' criteria (in terms of project performances: time, cost and standard of completed work) well" (Fellows et al. 1985). The report observed that "the existing contract forms and tendering procedures, which are designed for new-build projects are inappropriate for refurbishment projects as they do not give sufficient importance to the time requirements" (*ibid.* p.16). Fellows et al. emphasised that "refurbishment projects require an organic form of organisational arrangement which permits flexibility in the allocation of tasks and a collaborative attitude between the members" (Fellows et al., *loc. cit.*). Furthermore the report noted that there is a high degree of mismatch between the levels of clients' control over commercial refurbishment projects and the chosen types of contractual arrangements used for construction refurbishment works. Fellows et al. then concluded that modified contractual arrangements are required to enable the clients to accomplish the required control over projects in other to optimise the project performances.

2. The gap in knowledge of contractual arrangements for construction refurbishment projects.

Several studies have been conducted, attempting to set out criteria and guidelines in choosing a contractual arrangement for a given project (National Economic Development Office 1985; Hamilton 1987; Skitmore and Marsden 1988; Love and Skitmore 1996). Expert systems have also been developed (Brandon, Basden et al. 1988; Brandon 1990, Wong and Albert 1995), to provide guidance on the most suitable contractual arrangement for a given circumstance. However, these studies do not focus specifically on refurbishment works. Furthermore many of the existing studies on the theory of procurement selection are based on a positivist research paradigm and on the rationality of the individuals making procurement selection decision. Love and Skitmore (1996) have shown that the actual selection of procurement system is irrational. A framework involving a mu&paradigm research technique and the recognition of individuals bounded rationality is identified as a better option towards procurement selection.

The problem of procurement selection in the building and civil engineering sector will appear to have inadequately satisfied the majority of construction clients. It is argued that the various procurement selection systems available are primarily concerned with the identification of a generic approach that meets the determined requirements, regardless of contractual arrangement and notwithstanding that most contractual arrangements contain characteristics of each other (Prof. Hibberd and Basden 1996). It has been shown also that the existing standard contractual arrangements arc deficient in making explicit and allocating such risks as variations and time extensions which the main contractor bears by implication (Heath and Berry 1996). Heath and Berry (1996) pointed out that there is the tendency, as the complexity of the works increases, of passing the burden of risks to the sub-contractors and creating a sub-organisational management structure that is quite different to that existing at the main level, and in turn may lead to project conflict and subsequently to clients' dissatisfaction. Therefore the problem of high project performances (which the existing procurement selection models intend to achieve) lies beyond merely matching these deficiently drafted standard contracts with project types or clients' criteria but should include matching the content of these standard contractual arrangements to the intentions of the parties involved in construction transactions.

3. Research aim and objectives

The on-going research attempts to fill the gap in knowledge by developing an artificial intelligence system for the selection of contractual arrangements for construction refurbishment projects.

The set objectives of the study are as follows:-

1. To establish the criteria used in the selection of construction procurement methods for refurbishment works.
2. To assess the impact of the standard forms of contracts on construction refurbishment projects.
3. To carry out a quantitative evaluation of time and cost of construction refurbishment projects completed with various contractual systems. Both time and cost all have a number of aspects associated with them. These aspects are broken down and form part of the study.
4. To carry out a qualitative assessment of clients' satisfaction (with regards to the standard of completed refurbishment project) in adopting various contractual systems.

4. Research methodology

This paper is based on a thorough review of literature. At the time of writing, a pilot study is being carried out by the authors to identify procurement selection criteria with reference to construction refurbishment projects. The research strategy is designed to explore the subject matter with rigour with the aim of reducing the degree of subjectivity that may accrue from a study of this nature.

5. About the legal frame work of construction contracts

There are two related types of construction contracts - first are contracts of building works, i.e., residential development, industrial and commercial developments. The building works contracts may be contracts for new works, refurbishment, and restoration. The second type are the engineering and civil works contracts- these include, the construction of civil engineering infrastructures and a variety of engineering projects such as offshore projects, dams, roads. There is no legal distinction between the building and civil engineering works contracts. Their fundamental difference is based on the nature of construction work to be carried out

The law which governs the formation of construction contracts is in principle the same with that applicable to contracts in general (May, et al, 1995). Construction contract is defined as an agreement under which a person, called variously the builder or contractor undertakes for reward to carry out for another person, variously referred to as the building owner or employer, works of a building or civil engineering character (Wallace 1995). Construction contracts are complex relational transactions- an ongoing relation which needs continual adjustment (Veljanovski 1982).

5.1 Distinction of construction contract

A fundamental distinction of construction contracts from other forms of relational and simple contracts is that as the work proceeds and become fixed or attached to the land of the owner, it progressively and irretrievably becomes the property of the owner whatever the financial rights or obligations of the party may be at the time (Van Deventer 1993; Wallace 1995). It is argued (Van Deventer 1993) that the legal rules that govern contracts in general do not adequately address the complexities and subtleties involved in construction transactions.

5.2 Standard contract forms

Most construction contracts are transacted on standard forms. In the United Kingdom, the commonly used forms for building works are the set of standard forms published by the Joint Contracts Tribunal (JCT), The Institution of Civil Engineers (ICE) conditions are used for civil engineering works. The *Federation Internationale Des Ingenieurs Conseils* (FIDIC) standard forms are mostly used for international projects of civil engineering character.

Standardisation of contracts have a number of positive attributes: it reduces transaction cost i.e., the cost of completing a transaction by providing a set risk allocation terms for use by the parties. Standard contracts have the advantage that a legal decision in one case would very likely provide a guide to disputed problems in other cases (Atiyah 1995). It is being argued that the main advantage of conditions of 'agreement' contained in the standard forms is that they have the potential for improvements (Bubshait and Almohawis 1994). Bushait and Almohawis explained that by using the same standardised conditions consistently the clarity, fairness, and efficiency of the provisions will be tested, and areas of deficiency identified and subsequently corrected. Other advantages include their familiarity to the parties which reduces the cost of drafting and prolonged review of the conditions, and that the standard-form contracts *"lessens the possibility* of *misunderstanding, undue compensation, the likelihood of change* orders, *and the occurrence of claims* or *litigation arising out of contractual performance".*

The limitation of the standard-form contracts is that they violate the 'freedom of contract doctrine': contracts being an *agreement or promises* made between parties. Atiyah (1995) argued that many of the terms of a typical standard-form contract were not agreed to in any real sense, in that they are made of a set of fixed terms with little provision for variation. The forms are sometimes drafted by one party alone, and as Bushait and Almuhawis (1994) noted, they generally favour the sponsoring organisation. In other instances neither the parties drafted the contract as in the standard-forms of construction contracts, in which case *"both parties may have only the vaguest intentions as to what the terms of their contract actually provide"* (Atiyah 1995 :18). Atiyah observed that *"quite often, these standard forms were standard throughout the entire industry, being in substance, largely agreed forms of contract which were adhered to by all firms, thus depriving the consumer of the red benefits of competing and free choice".*

In addition to the limitations referred to above, the UK standard-form contracts used in the construction sector have received a number of criticisms. They have been criticised for there obscurity. A judge ones described the standard-form construction contract as *"a farrago of* *obscurities"(Per* Edmund Davies L.J. in English Industrial Estates Corp. v. George Wimpey & Co. Ltd.. [1973] 1 Lloyds Rep. 118, at p. 126). The printed forms are characterised by ambiguities and discrepancies on the terms incorporated in them (Wallace 1995), conflict between clarity and flexibility (Hughes and Greenwood 1996). The language used in their drafting is complex and often misunderstood by the parties. They are also adversarial in nature, being based on the law of contract which on its own accord is adversarial (Jones 1994).

6. About artificial intelligence.

In recent years a new inter-disciplinary field of interactive computer systems known as artificial intelligence has emerged. Artificial intelligence is concerned with the computations that connect situations to complex, human-like actions. Artificial intelligence encompasses some intelligent behaviours such as deduction and search, learning and explanation The main applications of artificial intelligence were found in programmes for processing and understanding natural language, understanding speech, information retrieval, automatic programming, robotics, scene analysis, game playing, fuzzy logic and mathematical theorem proving, There is now an increasing application of artificial intelligence in construction related problems such as in budgeting, bid selection as well as procurement selection.
Artificial intelligence may be distinguished according to its basic approach to knowledge representation. Four approaches are identified: logic, semantic networks, frames and rule based systems.

6.1 Application of artificial systems to procurement selection.

Artificial intelligence have been successfully applied to the selection of procurement paths for general construction despite the embryonic problems that exist with any new approach. Previous development of artificial intelligence for procurement selection include the works of Wong and Albert (1995) and Brandon(1990).

Brandon (1990) developed a system which ranks various procurement paths under headings which try and define the degree of appropriateness with a built in explanation facility. By weighting both the positive and negatives arguments by a number of plus and minus signs, the consultant can be able to check on his own thinking to assess the strength of argument in a particular direction.

Wong and Albert (1995) developed a fuzzy logic artificial intelligence for contract decision making in Hong Kong. Wong and Albert identified six core criteria used in contract selection: scale of the project, nature of works, characteristics of client, time constraint, the source of materials for construction and the characteristics of building design. These factors are used to develop a decision rule that enables the selection of a procurement route that is appropriate for the circumstance.

Expert systems have been used successfully in procurement selection as Brandon(1990) and Wong and Albert (1995) have shown despite the embryonic limitations particularly the subjectivity of the systems. The results of earlier studies show the feasibility and potential benefits of developing artificial intelligence for procurement selection specifically for refurbishment works.

7. Conclusion

The paper have argued that there is lack of guidance in the selection of contractual systems or procurement path for construction refurbishment works. The paper also identified the peculiarities of refurbishment works and the need to treat refurbishment as a distinct category of construction process. The legal frame work with which construction contracts operate in the UK is reviewed and the feasibility of an artificial intelligence in the domain of procurement selection for refurbishment projects is identified.

The paper then concludes that there is the need to develop an artificial intelligence system for procurement selection for refurbishment works. The benefits that could accrue from the development and application of an artificial intelligence in procurement selection are many and they include a dramatic improvement of efficiency in terms of the speed of reaching an informed decision, reliability of the expert advise as the system is built in with a robust expert knowledge and it provides a datum of knowledge distilled from an acknowledged experts.

Aligning Procurement Methods Toward Innovative Solutions to Environmental and Economic Needs

J. B. Miller
Department of Civil and Environmental Engineering, Massachusetts Institute of Technology, Cambridge, MA, US A

Abstract
The strengths and weaknesses of complex variations of Design-Bid-Build, Design-Build, Design-Build-Operate, and Build-Operate-Transfer processes are being explored at the project level. The resulting literature confirms that knowledge, experience, and judgment are required for success, and that choice of project delivery method affects the timing, nature, and scope of innovation in technology, design, construction, operation, and finance. The growing acceptance that there is more than one project delivery option for many public infrastructure projects necessarily implies new opportunities to package projects in order to optimize not just one, but a portfolio of infrastructure facilities. Procurement systems will offer sustainable management of society's infrastructure portfolio if the lessons learned at the project level are assimilated into simultaneous planning for the delivery of collections of projects. The basic variables will be (1) choice of project delivery method and (2) choice of project financing vehicle. A four quadrant framework for analyzing and comparing project delivery and finance methods is presented, along with a summary of the fundamental elements of a long term, public/private strategy for delivering, maintaining, and refreshing the infrastructure portfolio. A three quadrant model is described to implement this strategy. The objective function will be that combination of viable projects which meets the greatest number of environmental and economic needs within multiple capital rationing restraints. Discounted life-cyclecash flow analyses (DLCCF) will emerge as the common denominator that allows these variables to be mixed, matched, and evaluated in alternative portfolios. The benefits of open, transparent, competitive procurement strategies to government, the private sector, and the public are presented and described. Establishing a stable, flexible procurement system for improving the infrastructure base is a key prerequisite to addressing broader questions related to the economy and the environment.
Key Words: Build-Operate-Transfer, Design-Bid-Build, Design-Build, Design-Build-Operate, Discounted Life Cycle Cash Flow, Project Delivery and Finance, Project Portfolios, Public Infrastructure

1. Introduction

Ostensibly new, the problems facing today's generation of governments and infrastructure planners are, in reality, quite old. These problems include: (a) getting infrastructure development started or reinvigorated to improve economic efficiency and raise the standard of living; (b) starting and sustaining private sector entities such as architectural and engineering consulting firms, construction companies, design-builders, manufacturers of supplies and equipment, and developers of new technology; (c) building public sector institutions which facilitate economic activity, encourage competition, and increase the transparency of government regulation and legislation; (d) producing steady technological refreshment of infrastructure, including replacing "dumb" with "'smart", "dirty" with "green" systems; and (e) attracting both public and private sector investment of capital. Governments continue to search for stable procurement systems which let new ideas, new technologies, new capital, and new firms in, while allowing existing firms to grow and evolve. In the US, for example, this search is as old as the nation. (1)

2. The rebirth of project delivery and finance as variables

The biggest news in the world of public infrastructure procurement is the rebirth of project delivery and finance as variables in infrastructure planning. Over the last decade, the Engineering Procurement Construction (EPC) sector throughout the world has developed broad expertise in the full range of project delivery and finance methods -- including design-bid-build (DBB), design-build (DB), design-build-operate (DBO), and build-operate-transfer (BOT). The literature confirms that, for each available delivery method, substantial knowledge, experience, and judgment are required for success. After any one of these delivery methods is chosen, successful implementation of that method requires careful planning, detailed scheduling, timely materials and equipment acquisition, and proper integration of all the design and construction elements.

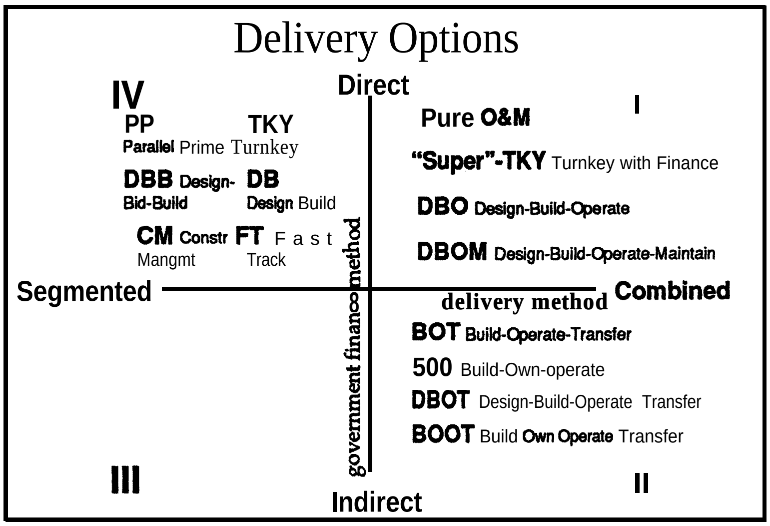
The growing acceptance that there is more than one project delivery option for most projects is directly correlated to the growing recognition that choice of project delivery method profoundly affects the timing and scope of innovation at each step in the infrastructure delivery process. Choice of delivery method directly affects choice of technology, design approach, construction methods, facility operations, and project finance. The emerging mix of project delivery and finance options necessarily implies new opportunities to package projects in order to optimize not just one, but a portfolio of infrastructure facilities. This paper explores the key elements of procurement in this new environment, and offers an integrated strategy intended to align infrastructure procurement strategy with both long term economic activity and appropriate stewardship of the environment.

2.1. Definitions

The term "infrastructure" is used in a broad sense to mean, collectively, (a) the transportation of people, goods, and information; (b) the provision of public services and utilities such as water; power; removal, minimization, and control of waste; and (c) environmental restoration. The term "project(s)" is used to refer generically to contracts awarded by public owners for the provision of capital works and/or infrastructure services.

Using metrics previously described by the author, (l-3) the Operational Framework represented by horizontal and vertical axes in Figure 1 was developed to describe the practical choices facing the public infrastructure sector at both the project and portfolio levels. The horizontal axis represents the continuum of delivery methods measured by the degree to which typical elements are segmented or combined with one another, while the vertical axis represents the continuum of financing methods measured by the degree to which government assumes the financial obligation for producing, operating, and maintaining the project throughout its life cycle. Superimposed on the framework in Figure 1 are the project delivery methods in common use throughout the world. Most of these methods are described by Gordon (4). Several variations of Design-Build-Operate and Build-Operate-Transfer are also included.

Figure 1



All the procurement methods shown in Figure 1 are defined in two dimensions: the means of project delivery and the means of project finance. The term OWNER refers to the public entity procuring infrastructure facilities or services, and CONTRACTOR refers to the successful bidder or proposer that emerges as the winner of the procurement process. DESIGN-BID-BUILD (DBB) is defined to mean a segmented delivery strategy in which design is fully separated from construction. Both are in turn fully separated from maintenance and operation of the facility once the project is turned over by the CONTRACTOR to the OWNER. In the DBB model, planning and financing of the project are also separately provided by the OWNER. DESIGN-BUILD (DB) is defined as a delivery strategy in which the-government procures both design and construction from a single CONTRACTOR. Initial planning, functional design, financing, maintenance, and operation of the facility remain as separate, segmented elements of the project, provided by the OWNER. DESIGN-BUILD-OPERATE (DBO) is defined as a delivery method in which design, construction, maintenance, and operation of the project are procured by the OWNER from a single CONTRACTOR. Initial planning and functional design are provided by the OWNER. As used in Figure 1, the DBO procurement method is defined to require that the public OWNER directly provide sufficient financing for the CONTRACTOR to perform all of the tasks assigned by the OWNER. This financing is typically provided in one of two ways (and sometimes as a combination of the two): direct cash payments by the OWNER, or delivery by the OWNER of the equivalent of direct cash payments to the CONTRACTOR, such as the right to collect user charges. BUILD-OPERATE-TRANSFER (BOT) is defined as a delivery method in which the OWNER procures design, construction, financing, maintenance, and operation of the facility as an integrated whole from a single CONTRACTOR. Only initial planning and functional design are provided by the OWNER. As defined here, the BOT method puts the risk that project receipts will not be sufficient to cover project costs and debt service squarely on the CONTRACTOR.

In actual procurements, owners present competing contractors with opportunities that vary slightly from these definitions. Such variations include: mixtures of direct cash payments and cash substitutes from the owner; the extent of initial planning or design; the length and extent of maintenance and operations obligations.

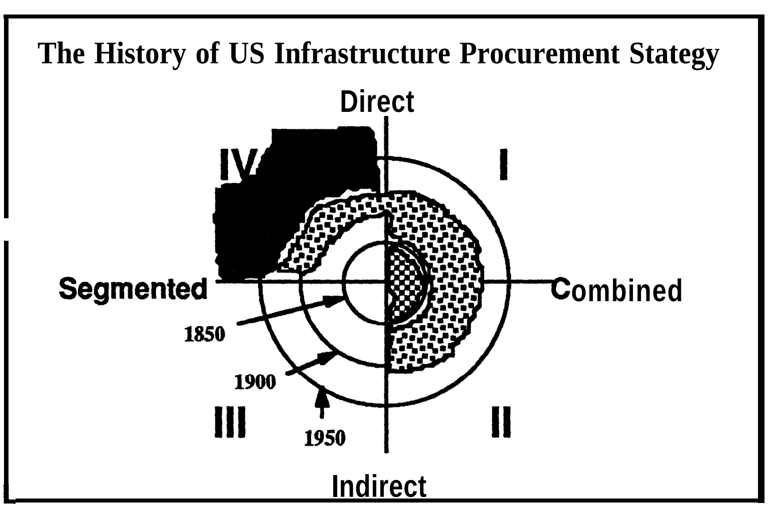
2.2. "Public or Private" - the empty, useless debate

Over the last ten years, many developed nations and international institutions that provide funding to developing nations have debated the relative merits of public and private provision of infrastructure facilities and services. Supposedly "deep" philosophic arguments over the "proper" role of government in infrastructure assumes that one such role can be identified - an assumption fundamentally at odds with the growing use of alternative project delivery methods. The debate is both hollow and futile. It is hollow because much of the world's infrastructure stock is already privately held, a trend that will likely accelerate, as the next major wave of infrastructure improvements -- information technology (IT) -- continues to be developed primarily in the private sector. It is also hollow because much of the "stuff' of publicly held infrastructure -- aircraft, railroad cars, ships, traffic controls, highways -- is not manufactured or installed by government at all, but by private companies procured by government. The public/private debate is futile because public funding levels across nearly all nations seem to be inadequate to meet government's appetite for world-class infrastructure to push national economies into the global economy.

Neither a purely public nor a purely private approach to infrastructure provision has proven to be sustainable in either the developed or developing world, particularly where financial and environmental resources are limited, and where innovations in the technology and methods associated with infrastructure continues to occur unpredictably throughout the world.

The US experience is a class example of one nation's two hundred years' experiment with various mixtures of public and private procurement strategies for infrastructure. Figure 2 presents how America has experimented with project delivery and finance methods, using the framework presented in Figure 1, modified by the addition of concentric circles representing the passage of time. Figure 2 summarizes over 800 statutes enacted by Congress prior to 1933 which led to projects, and several thousand projects funded through federal grants after World War II. (l-3)

Figure 2



America's current exclusive reliance on Quadrant IV for federal construction of public infrastructure has, since 1980, proven to be unstable because of chronic shortfalls in federal direct funding for infrastructure. The American experience is common to many of the world's nations, both developed and developing - with variations in timing and sequence. The "private v. public" tug of war for the heart and soul of infrastructure development continues in the US today, as competing ideologies argue for totally public infrastructure in Quadrant IV and totally private infrastructure in Quadrant II.

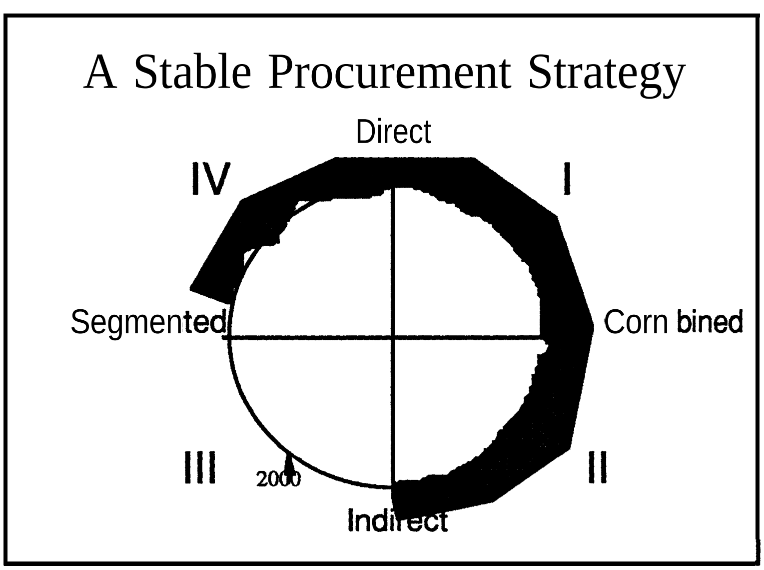
This polarizing debate now threatens to paralyze what would otherwise be an inexorable process of infrastructure renewal -- led by innovation in technology and methods, and pursued by entrepreneurs and investors. The danger is that both government and private industry will continue to see procurement strategy as an ideological choice between public and private rather than a steadily evolving mixture of both. technologies from around the world. The basic problem is how to produce and sustain a competitive infrastructure base without concentrating too much power in either the state or in the private sector, and at the same time maintaining incentives for individuals to innovate, to produce, and to improve both themselves and the infrastructure portfolio.

3. The underlying logic of procurement must change

Irregular, and often unpredictable shifts in government policy between purely public and purely private infrastructure send exactly the wrong message to designers, constructors , operators, investors, inventors, and individuals interested in making their contribution to the economy through public infrastructure. Such shifts merely confirm to decision-makers in the private sector that infrastructure is not a reliable market, and that more stable opportunities should be pursued elsewhere.

Our procurement strategy should recognize explicitly what generations of experience has already taught: innovations enter the infrastructure portfolio through each of the individual segments in the procurement process (design, construction, finance, operations, maintenance) and through combinations of these segments (DB, DBO, BOT). Only a broad mix of procurement strategies offers a stable base for broader economic and environmental strategies. Figure 3 describes this strategy graphically. No single quadrant strategy (Quadrant-IV or Quadrant II) is stable in the long term.

Figure 3



4. Fundamental elements of a sustainable procurement strategy

The fundamental elements of a procurement strategy incorporating the notion that project delivery and finance are key variables to be managed in the refreshment of the infrastructure portfolio have been previously described. (5) These elements are listed below in summary form for discussion and debate.

- A Three Quadrant Strategy in which a steadily evolving mix of public and private delivery/finance is the express goal
- Consideration of alternative project delivery and finance mechanisms as one means for verifying project viability, introducing new technology, and generating competition over quality, initial cost, and life cycle cost.
- Comparative discountedcash flow analyses of life cycle cost, in order to permit one to one comparison among the DB, DBB, DBO, and BOT contract awards.
- Project Scope, clearly defined in advance by the government, either through performance specifications, or design specifications.
- Competition in the award of projects, through well-advertised, well-marketed Requests for Proposals and Invitations to Bidders.
- Fair Treatment of Actual Competitors, through even-handed implementation of procurement processes.
- Transparency - Signaling Fairness to Potential Competitors through early statement of project and proposal requirements, and evaluation criteria.
- An Independent Engineering Check of the Efficacy of Design, to ensure public safety whenever the design function is combined with the construction function.
- Competition which is Open to Technological Change, through increased reliance on performance specifications.
- A portfolio approach to optimization, using discounted cash flow analyses over the project life cycle as the common denominator to compare alternative configurations of project delivery and finance for a collection of projects. (6)
- Continuous integration of these concepts into government procurement strategy.

5. Impacts on the economy, the EPC sector, and the environment

A three quadrant procurement strategy offers numerous opportunities for continuous evaluation of new technologies, techniques, and methods to improve the quality, cost, and environmental performance of infrastructure services and facilities. These opportunities naturally arise once the cost of current facilities and services become transparent to operators, users, taxpayers, and potential competitors, since the three quadrant strategy allows and encourages competitive pressures to replace “dirty” with “clean”, “dumb” with “smart”, and to steadily move the infrastructure portfolio toward better, faster, cleaner, and cheaper. The potential impacts on the economy, on the Engineering-Procurement-Construction (EPC) sector, and on the environment are significant.

5.1.1. The impact on innovation.

The three quadrant model permits innovations in technology to enter the infrastructure portfolio through any one of the delivery methods. The ownership, use, and rewards for innovative software can be more attractive to software developers where DBO or BOT is used, encouraging more rapid deployment of IT into control systems which integrate the functions of building, plants, and transportation systems. Improved energy conservation is a likely direct benefit.

With respect to innovation in architectural and engineering methods, the three quadrant strategy permits and encourages technology transfer of methods first employed in one quadrant to subsequent projects in other quadrants. A classic example of just such a transfer is the single gasket immersed tube tunnel design first employed on BOT projects on the cross harbor tunnels in Hong Kong, which has been. quickly transferred to the Boston Central Artery/Tunnel project, which employed-DBB as the delivery method. Innovations in construction methods are similarly transferable across the quadrants.

5.1.2. The impact on firms.

The three quadrant model encourages individuals to create and operate firms across the entire spectrum of activities associated with infrastructure development, including professional design, construction, design-build, supply, technology, operations, maintenance, finance, and combinations of these functions in broader organizations to perform DBO and BOT services. A stable, long term commitment by government to all three of the quadrants permits and encourages new entrants, and permits well established firms to compete for new opportunities in more complex markets that integrate design, construction and technology. The three quadrant model encourages firms to differentiate, to evolve, and to focus on infrastructure as an attractive market. (7, 8)

5.1.3. The impact on individuals.

The three quadrant model encourages individuals to contribute to infrastructure improvement in both new and traditional ways. Numerous points of entry and advancement are maintained through continued reliance on DBB and DB as bedrock delivery methods. Associated with these methods are traditional incentives for professional design education, practice, and licensure, as well as solid monetary incentives for the education, training, and apprenticeship of skilled craftsmen. The three quadrant model encourages entirely new groups of individuals to more actively participate in infrastructure renewal -- technology suppliers and financiers -- through the integrated procurement processes of DBO and BOT. In many of these procurements, technology, software, and finance will represent more important drivers in these competitions than engineering or construction elements.

5.1.4. The impact on competition.

The three quadrant model encourages stronger competition among firms, not only on initial cost for DBB and DB, but also on life cycle cost, time of performance, and quality of performance.

5.1.5. The impact on capital availability.

The three quadrant model encourages government to obtain independent checks of the economic and technical viability of large projects through DBO and BOT competitions. Such checks will gradually permit governments to adjust the allocation of projects across the quadrants so that private capital is reasonably and reliably attracted to viable projects in Quadrant II, and to those projects in Quadrant I where government financial backing (through cash substitutes) is clear. Private capital financing of such projects will, in turn, create new opportunities for government to better allocate direct cash payments to projects in Quadrants IV and I.

5.1.6. The impact on portfolio planning.

The three quadrant model makes scenario analysis possible, by expressly incorporating project delivery and finance alternatives into the planning process for a collection of projects, before procurement commences for individual projects. An early software appli that applies these principles to a portfolio has been developed at MIT, called CHOICES. (6) The purpose of the software is to permit alternative configurations of project delivery and finance to be explored by government planners before choice of delivery method is made.

5.1.7. The impact on government procurement institutions.

The three quadrant model necessarily implies a smaller, yet a more robust role for government in the planning, delivery, and operation of the infrastructure portfolio. Greater transparency is a substantial element of the model, including visible, reliable commitments by legislatures and regulators to: (a) a mixed delivery approach, (b) open technologies, (c) accurate statements of current costs and levels of performance, among other factors. In the three quadrant model, government has a special obligation to identify the public's functional infrastructure needs, to analyze the procurement options, to select among delivery methods, to conduct the competitions, and to monitor the results achieved, all as a prelude to repeating the entire process as technologies, skills, and needs evolve with time. Benchmarking against similar facilities and similar services provided by other governments can help to keep this process healthy and strong. Steady, sustainable improvement in the portfolio is the strategic goal.

6. Conclusion

The growing acceptance of multiple project delivery and finance methods necessarily implies that governments will be increasingly faced with strategic choices whether to use "public" or "private" mechanisms in the provision of infrastructure facilities and services. History teaches that purely public and purely private delivery mechanisms are unreliable, unstable, and averse to innovation. Steady, sustainable improvement in the infrastructure portfolio will be achieved through a transparent, -mixed strategy -- a three quadrant model -- which encourages individuals and firms to innovate, encourages technology developers and investors to enter, and which is simple for participants to understand and use. A flexible, reliable, mixed public/private procurement strategy is required if broader questions related to the economy and the environment are to be coherently addressed through procurement systems.

DESIGN AND MANAGEMENT PRACTICE FOR A SAFE WORKING ENVIRONMENT

A T Baxendale and 0 Jones
Faculty of the Built Environment
University of the West of England, Bristol, UK.

Abstract
Regulations for construction design and management for health and safety are examined in relation to clients, planning supervisors, designers, principal contractors and contractors. The paper is based on interviews with construction practitioners from small and medium organisations. Research findings are reported on issues of competence and the allocation of resources together with the preparation of construction phase health and safety plans. The competence of subcontractors has to be assessed and the need for their cooperation is noted. The responsibility for the implementation of the Regulations is included together with the recognition of training needs and the use of external consultants. The instilling of a safety culture is suggested as vital to the development of a health and safety system within organisations. The relationship between duty holders is noted and the cost of implementing the Regulations illustrated from a case study. A final conclusion is made that progress on implementation is slow on the part of clients and designers. Also that a greater focus is required on the awareness of risk to the health and safety of site operatives.
Keywords: Construction, design, health, management, regulations, safety.

1 Introduction

Health and safety requirements for a safe working environment are reviewed in relation to the implementation of The Construction (Design and Management) Regulations for the UK. Problems in meeting the requirements in terms of resources, responsibilities and management systems are reported. The methodology of the investigation was based on in depth interviews with construction practitioners (20) from small and medium sized enterprises and a detailed company case study.

2 Accidents and their costs

Construction work covers many activities, techniques, materials and hazards and it is this diversity that increases the probability of accidents occurring. There is a commonality of accidents within the industry and the factors that can contribute indirectly to an accident. An accident may be defined as any unplanned event that resulted in injury to ill health of people, or damage or loss to property, plant, materials or the environment [1]. A recurring theme is that people are killed during simple, routine work and in many cases a clear lack of planning contributed to the tragedy. An underlying belief is that the majority of accidents are not caused by careless workers but by failures in control which ultimately is the responsibility of management.

3 The Construction Design and Management Regulations

The Construction (Design and Management) Regulations 1994 came int effect on the 31st March 1995 and implements EC Council Directive 92/57/EEC which relates to the provision of minimum health and safety requirements at temporary or mobile construction sites. The regulations are considered to be more demanding than the minimum requirements of the directive.

The fundamental principles on which the CDM Regulations are based are as follows:

1. Safety is to be considered systematically, stage by stage, from the outset of the project.
2. All members who contribute to the health and safety on a project are to be included.
3. Proper planning and coordination must be undertaken from the outset of the project.
4. Provision of health and safety is to be within the control of competent persons.
5. Communication and the sharing of information between all parties must be included.
6. A formal record of safety information for future use must be made.

The CDM Regulations bring health and safety management, on an obligatory basis, into the planning and design of construction work. Thus the contractor is no longer left with the sole responsibility of health and safety during construction.

3.1 Clients

The philosophy of improving health and safety management by way of the regulations starts with an obligation to establish a team that will have the competence and resources to manage the project without any undue risk to health and safety. The appointment of a planning supervisor is central to a clients responsibilities. The planning supervisor should be appointed as early as possible to allow adequate time to address issues during the planning and design stage, including the preparation of the pretender stage health and safety plan. Any information in the clients possession should be made available to the planning supervisor.

3 .2 Planning supervisors

The post of planning supervisor is a new statutory requirement, which imposes duties but gives no powers. This appointment made by the client has the role of coordinating the design and planning from a health and safety viewpoint, with the aim of ensuring that risks identified in the construction of the project including those associated with maintenance or demolition are eliminated or minimised. The role involves the preparation of the pretender stage health and **safety** plan which is passed to principal contractors and the principal contractor will have the task of developing the plan. The client is entitled to advice from the planning supervisor, on the competency and adequacy of the health and safety resources available to designers and the principal contractor, prior to their appointment.

3 .3 Designers

Designers may include architects, consulting engineers, surveyors, specifiers, principal contractors and specialist subcontractors. The term “design” has a wide definition under the regulations and includes drawings, details, and specifications. The main requirement of designers is to deal with health and safety issues by designing them out “so **far** as is reasonably practicable”, that is by balancing the risk against the cost of averting it. A judgement has to be made so that the cost is counted not just in financial terms but also in relation to fitness of purpose, aesthetics, buildability or environmental impact.

The responsibility placed on the designer is to consider if the hazard can be prevented from arising so that the risk can be avoided. If this cannot be achieved measurements have to be taken to minimise and control the risk. The achievement of this will involve consideration not only of the construction but also how the completed project is to be maintained, repaired and demolished, together with those people involved in or affected by these activities. When there are risks that are not reasonably practical to avoid, information requires to be included with the design to alert others to the risks that they cannot reasonably be expected to know.

3 .4 Principal contractors

A client who intends to appoint a principal contractor has to be satisfied that the contractor has the competence to carry out or manage the construction work and has adequate resources to comply with the requirements imposed under the statutory provisions. Once the principal contractor is appointed they will develop the pretender health and safety plan into a working project document, ensuring that it has all the necessary information for securing the health and safety of all those carrying out construction work and those who may be affected by it.

All information relating to the project may not be available to fully develop the health and safety plan before work commences, but the general framework and key tasks during the initial stages should be included. When developing the health and safety plan, the principal contractor is required to assess the risks at each of the main stages within the construction phase. Information may be required from other contractors, including risk assessments and safety method statements, to facilitate this development. Finally, information held by the principal contractor which needs to be included in the health and safety file should be passed to the planning supervisor.

3 .5 Contractors

Contractors duties under the CDM Regulations are in support of those imposed on the principal contractor. Similarly they have responsibility for the health and safety of their own employees and others effected by their work under the existing health and safety legislation. The key duties are to give the principal contractor information on risk assessments, on how they propose to carry out the work and what steps they will take to control and manage any risks. This will require cooperation with the principal contractor and compliance with any directions given by them.

3.6 The Health and Safety Plan

The health and safety plan is a mechanism to improve the communication of matters affecting health and safety. The content and detail of the plan will be dictated by the size and complexity of the proposed project. During the pretender stage, the plan is prepared on information obtained from the client and designers and where appropriate the planning supervisor. The content of the plan, in addition to being relevant, should contain an indication of where principal risks occur in the design and the precautionary measures to be taken during construction. If there is a significant resource implication in dealing with an identified risk, tenderers will be required to respond on how this will be implemented.

3.7 The Health and Safety File

On completion of the project the planning supervisor is required to ensure that a health and safety file is prepared and handed over to the client. During the currency of the project those who carry out design work will need to ensure, so far as is reasonably practical, that information about any feature of the structure, which will involve significant risks during the structures lifetime, are passed either to the planning supervisor or to the principal contractor. The principal contractor may also require to obtain details of services, plant and equipment from specialist suppliers and installers.

4 Competence and allocation of adequate resources

The initial task for a principal contractor is to demonstrate competence to a prospective client. The standard means of adjudicating competence is by assessing responses to a pre-tender questionnaire. The validity of this method in isolation may be suspect and responses received do not necessarily reflect the true structure and strategy of a company with regard to health and safety. Planning supervisors whenever possible preferred to confirm the responses received by visiting principal contractors to carry out an informal interview. Pre-tender questionnaires are being given where the level of detail is disproportionate to the scale and complexity of the project. This has resulted, on several occasions, in smaller sized contractors declining to tender for work.

5 Preparation of construction phase health and safety plans

The findings indicate that initially principal contractors had encountered difficulty in preparing construction phase health and safety plans. The reasoning for a contrast in content and quality of the plans may be that the industry has not yet adopted a common format, although responses are found to be broadly based on the guidelines given by the Health and Safety Executive. Similarly there is no common format for the preparation of risk assessments, the majority having a format based on generic risk assessments provided by safety advisers. Evidence from planning supervisors is that the CDM Regulations have focused principal contractors on their duties under the Management of Health and Safety at Work Regulations 1992.

6 Competence of, and co-operation with, other contractors.

Only three of the companies interviewed have adopted a comprehensive procedure for assessing the competence of sub-contractors. Two of these had an accredited quality assurance system which encompassed the competence and monitoring of sub-contractors. The other companies relied primarily on the previous track record of the sub-contractor for assessment. Principal contractors are requesting health and safety related information from their sub-contractors but they are not ensuring that these contractors provided training and information for their employees. Co-operation is a requirement with all contractors, however once the sub-contract order is placed there is little to indicate any formal means of co-operation.

7 Responsibility for implementation of the Regulations

In all except two of the companies studied responsibility for preparation of health and safety plans and implementation of duties under the Regulations are the role of one senior manager. No one has employed extra personnel to assist with implementation and responsibility has fallen as an additional burden on the manager responsible for safety with in the company. The assessment of cost and time in preparing and updating the plan as carried out in a detailed case study indicates that the task takes up a significant proportion of a managers time.

8 Recognising training needs

The study has indicated a high awareness of the CDM Regulations amongst management in all companies. All companies, with the exception of the smallest sized company, have sent personnel on CDM related courses. The positive attitude taken by the companies studied in relation to management training is not mirrored in respect to operative training. Two of the companies have sent a small number of craftsmen on safety awareness courses as part of the requirement of a Construction Skills Certification Scheme. Membership of construction training groups is seen as a cost effective means by which companies can train and increase awareness amongst their operatives and a high proportion of companies interviewed were members of such a group.

9 Use of external consultants

A means by which small to medium sized principal contractors can display their competence to the client is by employing an external consultant or by being a member of a safety group. The services of a safety consultant who visits sites and reports on findings is deemed to be active monitoring and goes some way towards satisfying the monitoring requirements under the Regulations. External consultants can also advise on safety management systems and safety policies. A possible disadvantage of this approach is that documentation does not always directly relate to the specific company.

10 Instilling a safety culture

The owner managed companies studied have developed strong cultures despite the often cynical nature of the industry. The strength of safety culture is not as clear and success depends on how strong the owners exert a positive influence in relation to health and safety. Levit [2] has written that a leader who believes in safety gives direct evidence of this by holding all managers accountable for safety of their subordinates and by being willing to commit real and substantial organisational resources to training and monitoring safety related activities. In doing so the owners have to establish safety accountability within the organisation, train site managers in safety supervisory techniques, train site operatives in safe working practices, and require detailed preplanning of work.

11 Development of a health and safety management system

The development of a formal health and safety management system is seen to be essential for the control of risk. Within a company the pooling of knowledge and experience is a key aspect of risk control. Participation complements control in that it encourages the ownership of health and safety systems by employees at all levels. Participation also establishes an understanding that the organisation as a whole and those working in it benefit from a good health and safety performance.

A comprehensive system is made up of a variety of formal and informal means of communication by which there is an adequate flow of information throughout the organisation. However there is no clear indication that an integrated system had been adopted within the culture of the companies surveyed. The two companies with quality assurance systems have an advantage in that quality and safety were considered to be related. The Health and Safety Executive (HSE) [3] in its guide to successful health and safety management comment that organisations who have adopted a total quality management philosophy achieve particularly high standards of health and safety performance.

12 Relationship with other duty holders

The case study gave clear evidence that clients were, during the introductory period of the legislation, passing the planning supervisor duties on to the principal contractor. There is evidence of a lack of awareness on the part of the clients and a refusal to appoint a planning supervisor [4]. The research indicates that designers were initially slow to respond to the need for design risk assessments. There is also little evidence to show that buildability, a contributing factor to some accidents, is being considered.

The duties of a planning supervisor are as varied as the projects on which they are being asked to advise. The required core of competence is still being developed at the moment in what is becoming a new area of consultancy. The HSE recognises this and recommendations have been produced with suggestions for the training of those contributing to the design and planning supervision function [5].

13 Cost of implementing the Regulations

In the consultative document for the Regulations the Health and Safety Commission (HSC) estimated that the total cost to the construction industry in implementing the Regulations would be in the region of £550 million, based on an industry output of £37 000 million for 1991 [6]. The HSC estimated that compliance by designers for their new duties might cost an additional £290 million each year and the additional cost to planning supervisors and principal contractors an additional £185 million each year. The percentage of industry output costs for planning supervisors and principal contractors were therefore estimated to be 0.5% of the value of industry output. This figure is comparable with the case study where the cost of compliance was calculated to be 0.45% of the companies turnover.

14 Conclusion

The CDM Regulations are aimed at improving the overall management and coordination of health and safety throughout all stages of a construction project with the aim of reducing the number of serious and fatal accidents and causes of ill health that occur in the industry. The principle contractors interviewed have shown an awareness of their duties and introduction of the regulations has acted as a stimulus to demonstrate compliance in relation to health and safety. Risk assessments are now having to be prepared by contractors but there is evidence of disparity in their format and content.

Compliance with the CDM Regulations is a learning curve for all the duty holders and even for the enforcers. Pretender safety plans have assisted in focusing attention on prevention or control of risks prior to commencement of work on site. Difficulty has been encountered by small to medium sized principal contractors in the preparation of construction phase health and safety plans. However, planning supervisors have generally adopted a policy of working with principal contractors and assisting them in developing a format for the plan which will satisfy the requirements of the Regulations.

Input is required to communicate the CDM message to site operatives and subcontractors and the research has indicated that there is a need for the managers of principal contractors to instil a safety culture within their organisations from the top down. Health and safety management is a combination of practical knowledge, experience, knowledge of the law assessment of risk and effective control. The operation of an effective health and safety management system will facilitate traceability within a company should the HSE undertake an investigation.

The regulations were introduced with the intention of creating an integrated approach to health and safety through the increased involvement clients and designers. Some two years after the implementation of the regulations some duty holders are still addressing the issue of compliance. A finding of the research was that informed clients were discharging responsibility for the regulations directly on to principal contractors. Designers were not always taking a significantly different view as regards to the buildability of the structure and information on risk was not passing down to the operatives on site. If the purpose of the CDM Regulations is to reduce the number of accidents, this purpose is being clouded by practitioners unable to assess the requirements in proportion to the complexity and risks of specific projects. A review is required that moves the focus away from a paper bureaucracy towards a practical means by which principal contractors instil1 an awareness of risk to the health and safety of site operatives.

The role of procurement practices in occupational health and safety and the environment

J. J. Smallwood
Department of Construction Management, University of Port Elizabeth, Port Elizabeth, South Africa

Abstract
Inadequate, or the lack of health and safety negatively effects both the construction and built environments resulting in fatalities, injuries and disease. Procurement practices encapsulate inter alia: bidding practices; contract documentation, and project leadership, which in turn influence: client involvement; co-ordination of design and construction; design, details and specification; project priorities; project duration and project relationships.

To this end the findings of various descriptive surveys will be presented which indicate, inter alia: bidding practices; client involvement; design and details; project duration; partnering and the incidence of subcontracting to influence construction and occupational health and safety, ergonomics and the environment.

The need for procurement practices which enhance the construction and built environment, health and safety, and ergonomics included, is amplified by: the total cost of accidents; the cost of redressing unsuitable or polluted environments and the synergy between occupational, health and safety, ergonomics, productivity, quality, schedule and the environment.
Keywords: Procurement practices, health and safety, environment, cost

1. Introduction

The World Commission on Environment and Development [1] defines sustainable development as "Development that meets today's needs without compromising the ability of future generations to meet theirs".

The construction industry has wide environmental impacts, originating in land use, energy and natural resources consumption, pollution and upstream industries [2]. However, often environmental concerns are interrelated with construction health and safety issues [3]. Accidents not only result in considerable pain and suffering but marginalise productivity, quality, schedule, and negatively affect the environment and consequently add to the cost of construction [4]).

Barrett & Curado (1996) maintain that in order to sustain the present levels of satisfaction of the individual's higher level needs (social, esteem and self-actualisation) humankind is required to re-address the satisfaction of physiological and safety needs, by means of environmental preservation.

2. Impact of construction

Construction by its very nature represents an ergonomics, and health and safety problem as it requires, inter alia: bending; working in awkward or cramped positions; reaching away from the body and overhead; repetitive movements; handling heavy material and equipment; use of body force; exposure to vibration and noise, and climbing and descending [5].

According to March (1992) the industry impacts on the environment at a number of levels: globally; on the community at large, and fmally on the individual (Table 1).

Impact	Process	Effect
Global	Extraction	Energy, Timber, Water
	Materials manufacture	Energy, CFCs
	Building in use	CFCs (Refrigeration etc), Energy, Sewage
	Demolition	CFCs. Burning
	Impact of planning	All those Below
Community	Extraction	Noise/Dust, Traffic, Landscape, Ecology, Water
	Impact of design	Ecology, Aesthetics
	Construction phase	Site activities (noise, dust) Waste disposal, Traffic
	Building in use and management of the built resource	Noise, Traffic, Legionella, Fumes/Dust, Sewage
	Demolition	Noise/Dust, Waste Disposal &/or Reduction
Individual	Construction operatives	Health hazards, Safety
	Building user	Sick Building Syndrome (SBS), Legionella, Allergies, Fibres, Dusts, Pesticides Gases (random/volatiles)

Table 1: The construction industry's geographical impact [6].

3. cost

The cost of accidents can be categorised as being either direct or indirect. Direct costs tend to be those associated with the treatment of the injury and any unique compensation offered to workers as a consequence of being injured and are covered by workmen's compensation insurance premiums. Indirect costs which are borne by contractors include: reduced productivity for both the returned worker(s) and the crew or workforce; clean-up costs; replacement costs; stand-by costs; cost of overtime; administrative costs; replacement worker orientation; costs resulting form delays; supervision costs; costs related to rescheduling; transportation, and wages paid while the injured is idle [7]. Various studies have realised differing ratios between the indirect and direct costs: 1,67 times for non-minor injuries and more than 5 times for minor injuries with direct costs less than US$50 [8], & 20 times [9]. Research indicates the total cost of accidents to constitute, inter alia, 6,5% of the value of completed construction [10] and approximately 8,5% of tender price [11].

4. Potential practices

The United States Civil Engineering Research Foundation (CERF) 1994 study of leading construction industry practitioners, academics and government officials worldwide analysed five distinct, but interrelated areas of practice: management and business practices; design technology and practices; construction methods and equipment; materials and systems, and public and government policy. According to Dreger [12] the study provides an excellent base of common goals and issues which can be addressed to realise significant environmental improvements in sustainable development.

4.1 Total Quality Management (TQM)

According to Levitt & Samelson [13] TQM has as its main thrust continuous improvement in customer satisfaction, employee satisfaction, productivity, and health and safety. The TQM mission in construction is to realise a quality product i.e. an error-free one for the user by preventing errors in the construction process by integrating health and safety, productivity and quality.

Dreger [12] maintains the application of its principles has the potential of realising a quality project in all respects and beneficial results to all stakeholders. Preference should be given to designers and constructors who practice TQM.

4.2 Constructability

Constructability is a system for achieving optimum integration of construction knowledge and experience in planning, engineering, procurement and site operations, and the balancing of various project and environmental constraints to achieve overall project objectives [14].

The benefits of applying constructability management on the Toyota Car Manufacturing Facility at Altona, Australia include: completion ahead of schedule; below budget; to quality and health and safety standards [14].

4.3 Client influence
Clients influence health and safety both positively and negatively, either directly or indirectly. Indirectly through: project documentation; optimising project schedule; requiring of quality management systems (QMS's), and pre-qualifying contractors on health and safety. Directly through: imposition of permit systems; conducting health and safety audits; educating and training the personnel of contractors and referring to health and safety throughout the construction process [4].

4.4 Design influence
Designers influence construction health and safety and sustainable development as a result of project concept, design and -details, specifying materials and processes, advising regarding procurement systems including project documentation and project duration and interacting with clients with respect to health and safety [15].

4.5 Procurement systems
According to Dreger [12] the form of construction delivery affects contractual relationships and the development of mutual goals. Within the context of sustainability the Design-Build contract form, which establishes one entity to provide both design and construction, has the greatest potential for success as it creates common project goals.

Generally, although references are made to health and safety in standard South African contract documentation, it is indirect, hardly coercive, and depending upon the level of commitment, contractors continue to address health and safety to varying degrees. With the exception of indirect references to the construction environment, no references are made to the environment per se. Procurement systems are such that contractors frequently find themselves in the iniquitous position, that should they make the requisite allowances for health and safety, they run the risk of losing a tender or negotiations to a less committed competitor [16].

4.5.1 Pre-qualification
The purpose of pre-qualification in the health and safety sense is to provide a standardised method for selecting contractors on the basis of demonstrated safe work records, health and safety commitment and knowledge and the ability to work in a healthy and safe manner [17].

4.5.2 Partnering
Partnering brings the various stakeholders involved in a project: client; designers; general contractor; subcontractors, and suppliers together and entails inter alia, developing mutual goals and mechanisms for solving problems, which effectively complements health and safety [13].

4.5.3 Proj ect duration
Project duration can influence health and safety as a shortened project period invariably results in an increase in the number of workers; the number of hours worked per worker, or even a combination of the two; the amount of plant and equipment, and the number of subcontractors simultaneously undertaking work per period of time. This intensification increases the possibility of incidents [16].

4.6 **Systems**

Problems related to health and safety, productivity and quality can frequently be traced to substandard, inconsistently applied or non-existent operating procedures and practices. Standard operating practices and procedures are the core component of quality management and health and safety management systems as they guarantee uniformity of operation throughout an organisation. They effectively ensure that each' time a task is performed it is done consistently, correctly and safely [18].

Ultimately the implementation of a quality management system (QMS) on a project will ensure that construction conforms to specified requirements in all respects as it identifies the procedures, checklists, resources, activities and responsibilities [16].

4.7 Legislation

The promulgation of the Construction (Design and Management) (CDM) Regulations 1994 in the United Kingdom is attributable to two aspects. First the need for a radical improvement in health and safety resulting from a cultural change and adoption of a health and safetv culture bv all stakeholders in the industry: clients; designers, and contractors, from inception through to execution. Second, the Temporary or Mobile Construction Sites Directive (TMCSD).

The contractor no longer takes sole responsibility for site health and safety as there is now a statutory link between clients and designers, site health and safety, fatalities and injury [19].

5. Research

The salient findings of a number of descriptive postal surveys conducted nationally among various survey populations in South Africa are presented.

5.1 Project Management Practitioners

47 members of the Project Management Institute (SA Chapter) responded to this survey to determine the role of project managers in contractor health and safety.

5.1.1 Productivity and quality were the aspects identified most frequently as being negatively affected by inadequate health and safety (Table 2).

Aspect	Response (%)			
	Yes	No	Don't know	Total
Cost	72,3	19,2	8,5	100,0
Environment	66,0	23,4	10,6	100,0
Productivity	87,2	10,6	2,2,	100,0
Quality	80,8	17,0	2 , 2	100,0
Schedule	57,4	29,8	12,88	100,0
Client perception	68,1	19,1	12,8	100,0

Table 2: Aspects negatively affected by inadequate health and safety

Health and safety is a prerequisite for productivity and quality as, housekeeping, inter alia, complements access and ergonomics.

Accidents result in increased cost, damage to the environment and can substantially retard progress.

Clients' requirements include not only completion on time, to quality standards, within budget, but also without fatalities and injuries which can have a negative effect not only on a client's perception of a contractor, but on the contractor's and client's image as well.

5.1.2 95,8% responded that inadequate or the lack of health and safety increased project risk. Accidents and disease result in variability of resource which in turn increases project risk.

5.1.3 66% stated that health and safety is negatively affected by competitive tendering.

5.1.4 Pre-qualification of contractors on health and safety was advocated by 68,1%. Pre-qualification will ensure that health and safety conscious contractors are engaged. A contractor's commitment to health and safety is also an indicator of their likely approach to the environment and management in general.

5.1.5 Only 5 1,1% responded that health and safety is negatively affected by short proj ect periods.

5.2 General Contractors

71 contractors who are members of the Building Industries Federation of South Africa (BIFSA) or the South African Federation of Civil Engineering Contractors (SAFCEC) responded to this survey to determine the influence of design on health and safety.

5.2.1 Table 3 tables the frequency to which aspects of design can negatively affect health and safety.

Aspect/Factor	Frequency (%)
Design	50,0
Method of fixing	47,1
Content of material	38,6
Mass of material	38,6
Size of material	37,1
Edge of material	35,7
Position of components	28,6
Surface of material	27,1
Details	17,1
Area of components	14,3

Table 3: Aspects which can negatively affect health and safety

Design and method of fixing were probably identified due to it being difficult, or impossible to circumvent problems arising therefrom, whereas the wearing of personal protective equipment can circumvent, inter alia, edge and surface of material, albeit at expense, and in cases to a degree.

5.2.2 68% stated that health and safety is negatively affected by competitive tendering.

5.2.3 Pre-qualification of contractors on health and safety was advocated by 58,6%.

5.2.4 56,3% responded that health and safety is negatively affected by short project periods.

6. Conclusions

Construction impacts on both health and safety and the environment during the construction process and in the built environment. Accidents, disease and damage to the environment contribute to the cost of construction. Health and safety complements the environment, cost, productivity, quality, schedule, the environment, and therefore customer satisfaction.

Procurement systems, practices and legislation influence health and safety and environmental practices, all stakeholders – state, clients, designers, contractors, subcontractors and suppliers playing a role.

Design-Build contracts are the preferred procurement system as common project goals result more readily from the integration of design and construction. Health and safety and sustainability of the environment are enhanced by: constructability management which affords / engenders prioritisation of health and safety and the environment; partnering which facilitiates multi-disciplinary contributions; pre-qualification which ensures committed contractors are engaged; TQM which is the strategy to facilitate continuous improvement: QMS's which assure that work is executed correctly and consistently, and safe work procedures (SWP's) which assure that work is executed in accordance with process proved steps.

7. Recommendations

Legislation should be evolved that engenders prioritisation of health and safety and the environment by all stakeholders.

Health and safety and the environment should be included as project requirements.

Procurement systems should be evaluated in terms of their influence on health and safety and the environment prior to their selection for projects.

Practices such as constructability management, partnering, and pre-qualification should be implemented on projects.

The implementation of QMS's and SWP's should be made project requirements.

8. Acknowledgements

The author wishes to acknowledge Danie Venter, Director, Institute for Statistical Consultancy and Methodology, University of Port Elizabeth for the statistical

processing of data and the General Contractors and Project Management Practitioners who responded to the various surveys.

Exploring the cultural dimensions of construction procurement - dealing with difference to achieve sustainable development

A. Gilham ,
Centre for Sustainable Construction, BRE, Watford, United Kingdom
I. **Cooper**
Eclipse Research Consultants, Cambridge, United Kingdom

Abstract

The cultural characteristics of individuals and organisations impact directly upon relationships between construction suppliers, clients and others with interests in the built environment. This exploratory paper seeks to flag up some of the key cultural issues and dimensions which will be significant in attempts to improve the environmental impact of buildings.

Barriers to environmental improvements are presented alongside the range of values which motivate people to bring about those improvements. The paper emphasises the importance of understanding the individual, sectoral , organisational and national differences which are likely to be encountered. It offers preliminary ideas on how they might be recognised, using the framework of cultural dimensions developed by Hofstede.

Whilst the paper considers wide ranging issues it also presents two practices; Value Management and Partnering, as existing frameworks which are beginning to yield benefits for their practitioners, both customers and suppliers. They offer a way forward for sustainable construction procurement practice.

Key **words:** Procurement, culture, change, environmental improvement

1.0 Introduction

This paper examins how different groups located on the demand and the supply sides of the UK construction industry view the environmental improvement of buildings. The differences and conflicting views which are present throughout the construction supply chain act as substantial barriers to the application and development of environmental technologies, of new ways of working, and of general progress in tackling the more difficult issue of precisely what constitutes ‘sustainable’ construction. In this paper we present:

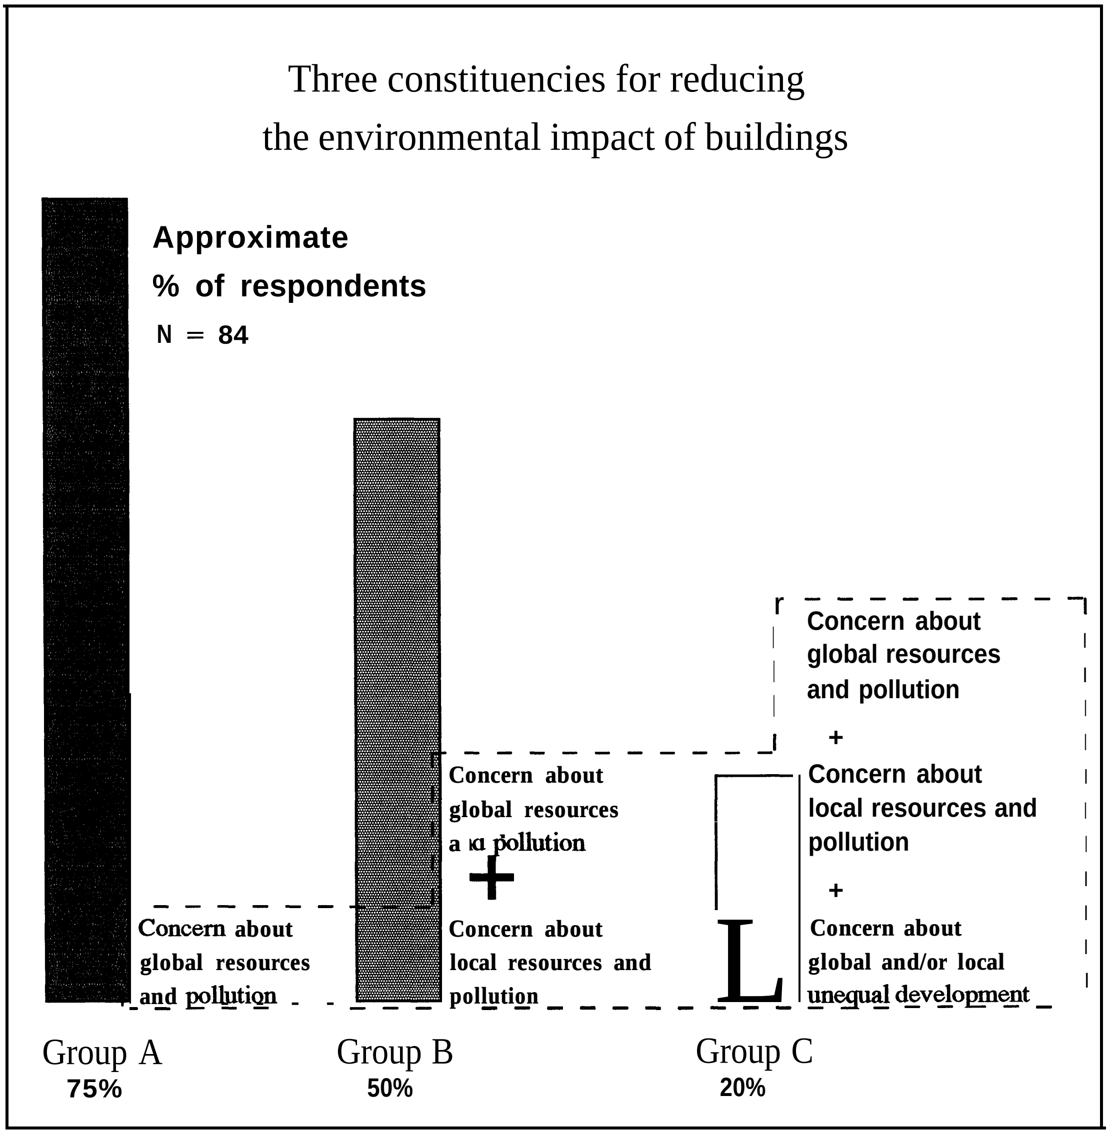
- some of the examples of difference encountered amongst those working for environmental improvement in buildings
- some of the barriers to the implementation of environmental technologies
- discussion, in the context of construction practice, the key cultural characteristics and dimensions,
- value management and partnering as new ways of working which accommodate these cultural issues

Change has been formally recognised as essential in the UK construction industry in order to bring about improvements to its productivity, efficiency, and quality and to reduce its costs. Fundamental cultural changes have been called for in The Latham Report “Constructing the team” **(1994) [1]**. Although these have not yet been achieved, new ways of working are emerging which can more easily accommodate the different (and sometimes conflicting)values of clients, designers and construction teams. ‘Value management’ and ‘partnering’ are two approaches which can yield dramatic benefits for their practitioners, both customers and suppliers alike. Like any change process, movement towards sustainability is more likely to succeed if this process is explicitly managed. This will require that more time, effort and understanding is devoted to managing the cultural components and dimensions of construction procurement.

2.0 Discovering differences amongst those involved in bringing about environmental improvements in construction

It is easy to assume that everyone involved in attempting to improve the environmental performance of buildings is working to a broadly similar agenda. The limited evidence available suggests otherwise, however. For example, Eclipse Research Consultants’ **(1996)** supply-side survey of the actions **[2]** which “leading-edge” architects and engineers in the UK said they were taking to reduce the environmental impact of new build and refurbishment work clearly identified the existence of three separable (but overlapping) agendas, see Figure **1.** This figure illustrates the percentage of respondents who said they were motivated by the three agendas described below.

Figure 1 Three overlapping agendas for reducing the environmental impact of buildings



Taken from Eclipse (1996)

1. The first agenda, Group A in Figure 1, is mainly focused on macro/global issues, of concern to global warming and ozone depletion., and, to a lesser extent, tropical rainforest destruction. Those concerned with this agenda are primarily acting to reduce the consumption of fossil fuels in buildings.
2. The second agenda, Group B in Figure 1, is wider. It also embraces these macro/global issues but adds to them more local or site- or project-specific ones (mainly to do with recycled or reusable materials and/or protecting or promoting local flora or fauna). Those focused on this broader agenda may also be concerned, for instance, with the specification of environmentally benign materials as well as the provision of nesting boxes for endangered bird species.
3. The third agenda, Group C in figure 1, is wider still. It embraces both the macro/global and local/site-specific issues of the other two and adds a third set mainly to do with public participation in decision-making and social equity. Those concerned with this broadest agenda may, for instance, be involved in self-build projects or in the use of unskilled labour drawn from the unemployed, or they may be concerned that their specifications and working practices conform to the emerging requirements of 'fair trade' and "ethical sourcing" both locally and globally.

Eclipse's survey showed that the narrowest of these agenda (Group A,) is the most frequently pursued (75% of respondents)and that the broadest (Group C,) is the least frequently encountered (20% of respondents). Clearly, there is an enormous difference here in the focus of attention, the range of issues considered and the underlying motives and aspirations of those pursuing these three agendas. These differences are rarely acknowledged yet they are substantial. Unless they are made explicit, they can be a severe stumbling block to effective collaboration, even amongst those who say they are committed to the environmental improvement of buildings.

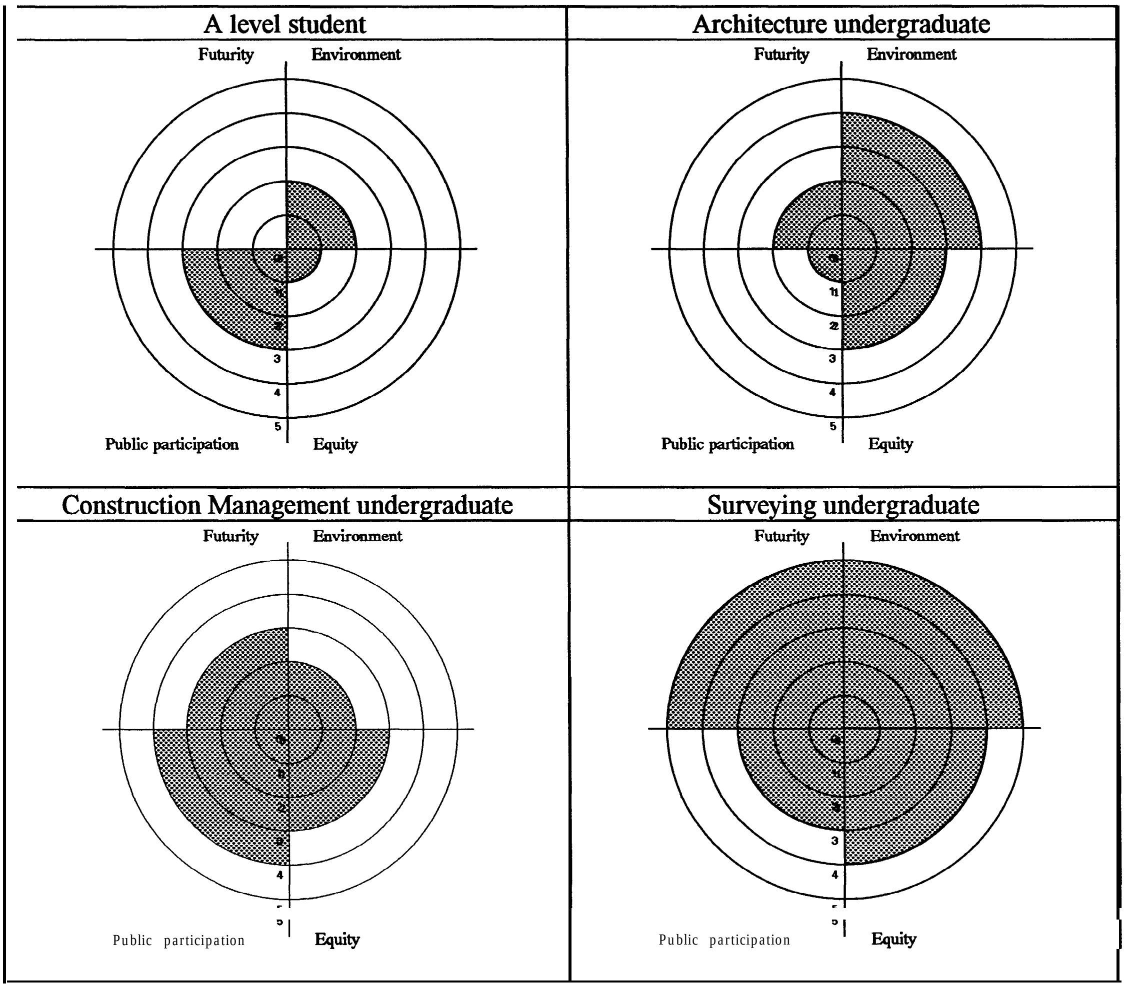
Similar differences emerge if we attempt to unpack the much more difficult notion of 'sustainable development'. As has been widely recognised by Palmer et al, 1997, this term is made up of 'fuzzy buzzwords' [3] - terms that appear to encapsulate a discrete notion but which have multiple interpretations. As a result, they are capable of appearing to unite people under what is actually a (falsely) shared umbrella. Eclipse have developed a simple, self-assessment, mapping technique [4] to allow people to gauge how committed they are to the four principles underlying sustainable development (Mitchell et al, 1995):

- futurity - concerns about future generations
- environment - concerns for integrity of eco-systems
- equity - concerns for today's poor and underprivileged
- public participation - concerns that individuals can participate in decision making

This technique has now been used widely - on the supply side with architects, engineers and building surveyors; on the demand side with client and building occupant representatives, with members of the general public, 'A' level school students and first year undergraduates in construction disciplines; as well as with a wide range of research communities involved in working on sustainable cities.

The results of using this mapping technique are revealing. We clearly cannot assume that other people share our own commitment to sustainable development, whatever that is. Some people are strongly committed to all four principles, others are uncommitted to all or some of them. Figure 2 [5], illustrates typical responses from a range of undergraduate professionals. Typically, whatever their background (age, sex,

Figure 2 Individual students' stated commitment to the principles of sustainable development



Taken from Cooper (1997)

Cooper, I., 1997, Designing on the Future: High Tech Sustainability?, Building Sights: Visions for the future of construction, Visions for the Future Report 6, Proceedings of a workshop organised by the British Association for the Advancement of Science on behalf of Technology Foresight and EPSRC, Salford University, 5-6 December, 1996, British Association for the Advancement of Science, pp. 4-7.

or occupation), undergraduates in the UK and from elsewhere in Europe are fairly strongly committed to one or more of the principles. On average (but not universally), they are most committed to 'futurity' and ‘environment’, less so to ‘public participation’, and least to ‘equity’.

The surveys have shown that, perhaps counter-intuitively, older people tend to be more committed to the principles than younger ones. And as much divergence in commitment can be found within the responses from particular age or occupational groups as there is between them. No one group has a monopoly on commitment; or is their age, sex or occupational group a strong predictor of how committed an individual 1s.

The results of the work reported above have clear implications. It suggests that we cannot afford to make assumptions about those we work with or for. We cannot take for granted what other people involved in the procurement or management of the built environment believe about how the environmental performance of buildings should be improved, or think about how construction should be made more ‘sustainable’. Their motives and aspirations for acting, and the narrowness or breadth of their agendas, are not necessarily compatible with ours. So for effective interactions we need to make clear:

- where we each stand on these issues
- how much common ground we and those we are working with occupy, and
- where and when we need to disagree amicably if progress is to be made.

3.0 Encountering difference in the design and procurement process

In practice also, there are many types of difference (such as values, priorities, time horizons, etc) which act as barriers to the implementation of change. These have previously been identified in the area of new environmental technologies. Gilham [6] identified key barriers which arose owing to a range of differences. Key conflicts arising included:

- a reluctance on the part of funders to adopt innovative technologies until they know they work and unless they have a long term occupier/tenant appeal.
- a reluctance by all parties to try new ideas owing to the risk factor for a specific group.

These two issues are typical of a low-risk tolerant construction industry which is dominated by contractractual relationships. These are key issues raised in “Constructing the Team”, a review of the UK construction industry carried out by Latham in 1994 [1]. The longevity of the product (i.e. a building) is also a contributory factor giving rise to the paradox of a long term product stemming from organisations with short term business strategies. Further issues identified in the research included:

- an overwhelming misperception that the different parties involved in the construction process have insufficient knowledge of energy efficiency to specify what they want or give good advice.

- a lack of hard data in client organisations about capital and running costs associated with energy efficiency.
- an overestimation by designers of their potential influence on clients in relation to other parties. Issues that drive clients' decisions are not high on designers' priority lists. Therefore designers cannot always use their good understanding of energy efficiency to good effect when advising the client.

The appropriateness of the information for each of the groups in the process needs to be considered very carefully. BRE's experience with improving energy management [7] within organisations indicates that data and information is not easily transferrable between different interest groups. The diverse needs of financier, developer, architect, engineer, cost controller, project manager, supplier and researcher require specific consideration. Factors such as language, format, timescale, organisational and personal values, skills base and learning styles, all have an effect on the accessibility and relevance of the information to each user group.

4.0 Cultural dimensions - understanding difference.

Difference manifests itself in many ways. We have explored above how various factors impact upon attempts to bring about environmental improvements in construction. Here we consider the dimensions of culture as a source of that difference which affects the decision making priorities of the different organisations and professionals. We should consider how the unconscious application of peoples' different values, as the core element of their culture, often leads to the conflict and the subsequent lack of resolution, change and progress which are needed if we are to achieve sustainable development.

4.1 Culture

There are three basic elements to our human programming:

- human nature, which is universal and inherited
- personality, which is specific to the individual being partly inherited and partly learnt.
- culture, which can be described as being learnt and specific to a social group or category.

Cultural differences manifest themselves in many ways and in varying degrees of permanance, such as:

- symbols - words, gestures , pictures or objects conveying meaning which is recognised by those who share the culture
- heroes - persons dead or alive, real or imaginary, who possess characteristics which are highly prized in a culture
- rituals - collective activities, technically superfluous in reaching desired ends, but which within a culture, are considered socially essential.

These three layers can be grouped as "practices" which form the outer and more easily altered layers of culture. The inner core of culture is "values", described by Hofstede [8] as "broad tendencies to prefer certain states of affairs over others". The values which people hold determine how they approach the decision making process and also what outcome they will feel comfortable with. We can see how the "practices" can change over time both in a broad societal context and in the context of organisational cultures[9]. However, "values", the inner core, deal with issues such as: evil vs good; dirty vs clean; ugly vs beautiful; natural vs unnatural; normal vs abnormal; paradoxical vs logical; rational vs irrational. As they are amongst the first things we learn as children, they are the hardest to change with many remaining unconscious to those who hold them.

4.2 Measures of difference

People carry many layers of mental programming for the different groups in which they live and work. Layers of culture exist at national, regional or ethnic grouping , gender, generation, social class, and organisational levels. Systematic research on values is cumbersome and ambiguous. However, Geert Hofstede, Professor of Organisational Anthropology and International Management at the University of Limburg in the Netherlands, has carried out extensive research which has resulted in the identification of five key dimensions of culture:

- Power distance
- Masculinity/femininity
- Uncertainty avoidance
- Individualism
- Short and long term orientation

These were developed as part of a world-wide study [8] in over 50 countries during the mid eighties. Hofstede identified many characteristics typical to each of the dimensions. It is these characteristics which we will use as the basis of discussion and review for the differences which are being encountered in the building procurement process.

4.3 Issues of culture for discussion - mapping onto the identified difference

The power distance index is an indication of attitudes towards relationships with other people based on position and roles within society. It reveals the attitude towards authority and also of how people will be motivated or de-motivated by the dominance of power.

Cultures demonstrating a small power distance index will typically strive for: minimisation of inequalities; interdependence between less and more powerful individuals and organisations. They will prefer less heirarchical frameworks and will favour decentralisation with a range of people involved in the decision making process.

Conversely, cultures demonstrating a high power distance index will: feel more comfortable with inequalities in society; manage through heirarchical structures; be more directive and unwilling to discuss and share problem solving. Authority and centralisation will be popular.

Looking to the construction industry, we might identify design consultancies typifying the team approach to problem solving and having a small power distance index and major client organisations such as local authorities and MOD, as more heirarchical. Heirarchies also tend to develop in larger organisations and can be identified as the dominant structure for major contractors. A conclusion from this, which would be supported by many designers and was identified in [6], is that designers can often be excluded and alienated from key decisions made in the design and procurement process.

Differences described by the "masculinity/femininity" index typically manifest themselves in the workplace in the following ways:

- attitudes towards relationships - where the more feminine cultures value the maintenance of relationships over tasks and performance which are highly prized in masculine cultures
- attitudes towards conflict - where negotiation and compromise are key words typifying the approach in feminine cultures and conflict, "fighting them out", toughness, assertion and ambition are words which typify masculine cultures.
- attitudes towards decision-making - where masculine cultures demand facts and proof, whilst feminine cultures trust more in intuition and consensus

These differences are not specific to men and women. Instead they characterise approaches which are evident across the sexes such as in the researcher or financier who requires "evidence" and "proof' and the entrepreneur who follows his or her intuition. There is a very strong correlation between those nations which scored the lowest masculinity rating in Hofstede's research - Sweden, Norway, Netherlands and Denmark and those which are recognised as leaders in environmental improvement activities.

A culture with a strong uncertainty avoidance index is typical for many client groups of the construction industry. This index measures the ability to live with risk, uncertainty and change and could be usefully explored for the construction process itself which is structured to eliminate and penalise changes occuring during the process. Cultures with a weak uncertainty avoidance: require few rules; enjoy learning, discovery and innovation; tolerate deviation. However, the inherent insecurity in life is felt as a continuous threat for cultures with a strong uncertainty avoidance index. There is a fear of ambiguity, with an emotional need for rules and "right" answers to questions.

This characteristic, when combined with the masculinity/femininity characteristics, can lead to widely different approaches to innovation and change. Interestingly the four nations previously mentioned above all appear as low scorers on the uncertainty avoidance index (i.e. they tolerate uncertainty).

The "individualism index" measures collectivism, thinking in terms of "we",or individualism, thinking in terms of "I", within a culture. Differerences manifest themsleves in the workplace in a variety of ways. For collectivists identity is based on social networks; relationships prevail over task (links with femininity); with harmony preferred to direct conflict; management is management of groups; and the employer - employee relationship is perceived in moral terms, like a family link. For individualists: identity is based on the individual; speaking one's mind is revered; management is management of individuals and employer-employee relationships are supposed to be based on mutual advantage.

Short and long term orientation was the fifth dimension which Hofstede identified after studying more closely oriental cultures. Attitudes towards long and short term decision making could have the greatest impact on improving environmental performance in buildings and the achievement of sustainable development. The concept of "investing in the future" is central to definitions of sustainable development and lead to the paradox referred to earlier which is familiar to the construction industry, i.e. satisfying short term needs of clients with a long term product . Typical characteristics of short term orientation include: respect for traditions and social obligations with a need to "save face"; a pressure to "keep-up" even if overspending although investing minimally; quick results expected; and concern for possessing "the truth". Characteristics of a long term orientation are: adaptation of traditions for modern use with subordination to purpose; perseverence towards slow results, valuing investment; thrift - being sparing with resources; and respecting the demands of virtue.

5.0 Procurement practices - Value management and Partnering

For practitioners in construction procurement the demand for sustainable development brings about increasing complexity. "Culture", "values", "innovation", "change", are complex and emotive issues which often appear confusing and obstructive in the work place. However, largely driven by the demand for greater efficiencies and to improve the "customer focus" in the UK construction industry, Value Management and Partnering, have evolved which are now showing considerable benefits to the customers of the industry and members of the design and construction teams. These accommodate the diverse values of client design and construction teams and provide the basis for sustainable procurement practice.

5.1 Value Management

Value Management focuses on producing a better definition of the client's requirements. Value management should not be confused with value engineering which can be described as the provision of function at least cost. Value management requires that a careful analysis of "need" is carried out. Here all possible requirements of a client are considered prior to commencing the normal procurement process.(ie design, pricing, detailed design, construction) The benefit of this is that the full range of skills can be applied to finding solutions for the client. Priorities are defined - in terms of value and importance - and then design, procurement and construction solutions are applied to deliver those priorites throughout the development process. The structure allows for review and the introduction of changing priorities occuring during the process. Value Management is particularly applied to projects with high value and high strategic risk.

The key stage in Value Management is the beginning where, usually in a facilitated workshop environment, the customer and supplier teams combine to:

- share aims and aspirations
- share values and identify priorities
- identify shared and individual benefits
- define decision making protocols
- set and agree strategic objectives
- set and agree means of measurement of success, and
- establish the partnership.

5.2 Partnering

Partnering is a term which describes an approach to construction procurement which can (and often does) eliminate competitive tendering as part of the process. A partnership is built between customer and supplier(s) which can be strategic, ie set up with a long time horizon, or project-based (where the partnership is established for the duration of the project alone). Inevitably there is a process of comparison, often at the very outset of the process where clients make a selection of potential partners from a proposal or submission. However, selection criteria are a combination of cost, quality, approach, style and skill in partnering. One example of this approach is illustrated by Southern Water Services [10] for the selection of the project-specific partners for a major civil engineering project in the UK. Here, the selection procedure included a series of questionnaires, interviews and presentations which focused on the experience and culture of the organisations and the people rather than the fee rates.

There are three key elements which define "partnering". They are:

- mutual objectives - shared by the partners on both customer and supply sides.
- problem resolution - where a process of conflict resolution is agreed at the outset of the partnership
- continuous improvement - where partnership aims to learn and build its capabilities from one experience to the next. This element includes the process of evaluation, feedback and review.

Collectively, these three elements describe an approach to construction procurement which was encouraged by Latham and is being taken forward by the Construction Industry Board.

What the practices of value management and partnering do is provide a working framework in which the different values of the client and the procurement team can be harnessed to good effect. They are therefore a useful starting point to identify new ways of working that will accommodate the diverse values and needs of clients who demand a sustainable built environment.

6.0 Construction procurement - managing cultural change

Within the context of developing sustainable construction procurement practices, this paper has explored the links between environmental improvements in construction and the cultural dimensions and characteristics of those involved in the supply chain. The differences and conflicting views which are present throughout the construction supply chain act as substantial barriers to the application and development of environmental technologies, of new ways of working, and of general progress in tackling the more difficult issue of precisely what constitutes 'sustainable' construction.

Wide ranging and significant differences are encountered in the UK as elsewhere in Europe. Some sets of cultural characteristics appear more attuned to improving the environmental performance of buildings and to moving towards a sustainable built environment than others. Yet the significance of these characteristics, and the importance of deliberately trying to nurture them (especially where they are currently absent) is seldom discussed - particularly in discussions of what constitutes "sustainable" construction.

Cultural change has been formally recognised as essential in the UK construction industry in order to bring about improvements to its productivity, efficiency, quality and to reduce its costs. Fundamental cultural changes have been called for. Although these have not yet been achieved, new ways of working are emerging which can more easily accommodate the different (and sometimes opposing)values of clients, designers and construction teams. 'Value management' and 'partnering' are two approaches which can yield dramatic benefits for their practitioners, both customers and suppliers alike. These practices require that more time, effort and understanding is devoted to managing the cultural components and dimensions of construction procurement. Like any change process, movement towards sustainability is more likely to succeed if this process is explicitly managed.

In order to increase the chances of achieving sustainable construction, we need to recognise that the role of individual, group and national cultural characteristics deserves much more time, effort and understanding than we currently afford them. For successful developments, especially in the context of combating unsustainability, will need to consider the values, aspirations and motives of a broader range of players than traditionally has been necessary in construction procurement. These players will have to stretch beyond the individual project/client-base, as well as beyond the supply side of the individual design/construction team. Eventually, to match the principles underlying sustainable development, our construction procurement protocols will have to be capable of accommodating other (currently unrepresented) stakeholders, especially those involved in processes for regulating the production, maintenance and replacement of the built environment.

7.0 Acknowledgements

This paper is based on various studies and interactions, including through the BEQUEST network which is part-funded by the EC. Both authors participate in a range of UK initiatives funded by the UK Government through the DETR Partners in Technology programme and EPSRC Sustainable Cities programme.

Health and safety and the environment as project parameters

J. J. Smallwood
Department of Construction Management, University of Port Elizabeth, Port Elizabeth, South Africa

Abstract
Traditionally, cost, quality and time have constituted the parameters within which projects have been procured and managed. This traditional approach has been perpetuated by inter alia: tertiary construction education, clients, designers, project leaders and the construction industry. However, the traditional approach has not been successful with the greater percentage of contracts not being completed within budget and to schedule and quality requirements. This non-realisation of the traditional project parameters (requirements) is largely attributable to the exclusion of health and safety and the environment which complement cost, productivity, quality and schedule as the result of the synergy between them. This synergy in turn is the essential catalyst for Total Quality Management (TQM) – the continual improvement of the construction process.

To this end the fmdings of various descriptive surveys conducted among general contractors and project managers will be presented which substantiate the synergy, inter alia: positive influence of health and safety on productivity, quality and the environment.
Keywords: Project parameters, health and safety, environment

1 Introduction

The traditional concern of designers and constructors has been the protection of constructed items from the effects of the environment. However, recently it has been realised that construction projects may have environmental implications from: the materials used; the nature of the design; the method of construction; the location and layout; the physical structure itself or the use to which it is put, and the effect of construction operations and products on the environment [1].

Occupational disease, fatalities and injuries are not project requirements and result in an increase in the cost of resources as a result of medical care, rehabilitation, compensation insurance, pensions payable in the case of fatalities and ancillary rework [2].

2 Statistics

Table 1 indicates the nature and extent of the injury problem in South African construction. It should be noted that occupational health and safety statistics are only available six years in arrears in South Africa.

Class of injury	Total No.	No./Class of injury/	
		Working day	R100m Construction completed
Fatalities	189	0,8	0,8
Permanent disablement	946	4,1	4,0
Temporary disablement	7 645	33,0	32,1
Medical aid cases	10 108	43,6	42,5

Table 1: Injuries per working day and per R100m (US$20,83m) construction completed in South Africa for the year 1990 [3] and [4].

Other salient statistics according to the Compensation Commissioner[4], Federated Employers Mutual Assurance (FEMA) [5] and the South African Reserve Bank (SARB) [3] are:

- The Disabling Injury Incidence Rate (DIIR) of 2,03 in 1990 means that 2,03 workers per 100 received disabling injuries [4].
- The Severity Rate (SR) of 3,86 in 1990 means 3,86 days were lost per worker [4].
- The total of 1 620 046 days lost as a result of fatal and non-fatal accidents in 1990 is the equivalent of 6 983 work days lost for every work day [4] and [5].
- The Fatality Rate in 1990 was 53,5/100 000 workers [4]. This does not compare favourably with the rates of selected countries for 1992: Japan (19); United States of America (18,6); Germany (14); Australia (11); Canada (7,4); Sweden (6), and The Netherlands (3,3) [6].

3 Reasons for considering health and safety

The reasons for considering health and safety are: the human factor; legislation; financial issues, inter alia, fines, cost of accidents and benefits of health and safety;

client pressure; cost of training replacement personnel; pending Construction (Design and Management) Regulations which will link clients and designers to site health and safety; attitudes of the court relative to liability of stakeholders in terms of comrnon law in the event of accidents, and the costs of reinstating the environment as a result of accidents [7].

4 Reasons for considering the environment

There are three reasons the industry needs to act: to pre-empt unfavourable consequences as a result of the increasing array of environment-related statutes, regulations and policies; to prepare for the changed nature of items it will be required to design, construct and manage, the new materials it might have to use and the processes it will have to adopt, and to contribute to overall environmental related efforts and issues [1].

Pitney [8] maintains the perception exists that the construction industry is insensitive to the environment, profit motivated and destroyers of the environment rather than protectors.

5 Health and safety and the environment

Environmental concerns are often interrelated with construction health and safety issues [9]. Unhealthy and unsafe practices, inter alia, concrete run-off or spillage, fires, oil spillage, waste and uncontrolled sanitation impact negatively on the environment. Generation of dust, hazardous materials and the release of non-biodegradable material into the environment contribute to the impact [10].

6 Cost of accidents

The cost of accidents can be categorised as being either direct or indirect. Direct costs tend to be those associated with the treatment of the injury and any unique compensation offered to workers as a consequence of being injured and are covered by workman’s compensation insurance premiums. Historical records can be reviewed to determine the amount of expenditure attributed to each particular injury. The indirect costs are those which are hidden and for which no historical record is kept. However, indirect costs are identifiable, but only ‘hidden’ in that they are not attributed to injuries in a bookkeeping sense [11]. Indirect costs include: reduced productivity for both the returned worker(s) and the crew or workforce; clean-up costs; replacement costs; stand-by costs; cost of overtime; administrative costs; replacement worker orientation; costs resulting from delays; supervision costs; costs related to rescheduling; transportation, and wages paid while the injured is idle. Various studies have realised differing ratios between the indirect and direct costs: 1,67 times for non-minor injuries and more than 5 times for minor injuries with direct costs less than US$50 [12], and 20 times [13]. Research indicates the total cost of accidents to constitute, inter alia, 6,5% of the completed construction [14] and approximately 8,5% of the tender price [15].

7 Environmental cost

The environmental cost resulting from the construction process and the built environment is substantial [1]. Much energy is used: in the production of materials such as cement, steel, aluminium, wood products, plastics and paints; the movement of materials and components to sites; the running and operating of plant and equipment on site and in the heating or cooling, or running of the machinery in completed buildings.

About 50% of atmospheric carbon dioxide is emitted from buildings and about 50% of all CFC's, which contribute to the long term depletion of stratospheric ozone as well as global warming, are used in building services as well as in insulation materials.

Sick Building Syndrome (SBS), where poor air quality, lighting and airborne pollution lead to various ailments and ultimately lost productivity among office workers. The annual loss in The Netherlands is estimated to be in excess of US$l billion.

Construction and human waste resulting from the construction process and the built environment respectively, result in, inter alia, the waste of land resources and contamination of natural resources and ecologies.

8 Synergy

A healthy and safe workplace complements cost, productivity, quality and the environment [10]. Hinze [16] maintains outstanding projects are: either ahead of or on schedule; within budget and reflect exemplary health and safety.

9 Benefits of health and safety

According to Pomfret [17] benefits include: less injuries; less property damage; less down time; improvement in morale; enhanced industrial relations; increased productivity; reduced cost, and enhanced quality. Other benefits include: less compensation insurance; fewer hidden costs; improved supervisor morale; increased efficiency, and improved marketability [18].

10 Project requirements/goals

According to Hinze [16] health and safety is vitally important, not just cost, quality and time because if a worker has been permanently disabled or killed, then a project is not a success. Total quality includes health and safety and all requirements are achievable concurrently. Levitt and Samelson maintain quality includes productivity and health and safety [18].

Successful project goals include environmental sustainability [19] and Ofori contends that the environment should be the fourth goal on construction projects [1]. Research conducted in the United Kingdom determined health and safety to be one of the five main criteria for contractor selection [20].

All the projects which received awards in the Australian Third Natural Excellence Awards for 'best practice' involved unique and special challenges, inter alia, stringent cost and time constraints, sensitive environmental issues and health and safety [21].

11 Research

The salient findings of a number of descriptive postal surveys conducted nationally among various survey populations in South Africa are presented.

11.1 General contractors

78 metropolitan area based general contractors who are members of the Building Industries Federation of South Africa (BIFSA) or the South African Federation of Civil Engineering Contractors (SAFCEC) responded to this survey to determine the influence of management on health and safety.

11.1.1 Most contractors viewed health and safetv to be important (Table 2).

Importance of Health and Safety	Response (%)
Verv	42.9
Important	44.1
Fairlv	10.4
Not	2,6
Total	100,0

Table 2: Importance of health and safety

11.1.2 The benefits of health and safety improvement were both quantitative and qualitative (Table 3).

Nature of improvement	Response (%)
Reduced accident costs	41,4
Increased productivity	37,9
Fewer complications	37,9
Workmen's compensation rebates	20,7
Other	10,3

Table 3: Benefits of health and safety improvement

11.2 Project management practitioners

47 members of the Project Management Institute (SA Chapter) responded to this survey to determine the role of project managers in contractor health and safety.

11.2.1 95,8% responded that inadequate or the lack of health and safety increased project risk. Accidents and disease result in variability of resource which in turn increases project risk.

11.3 General contractors

71 metropolitan area based general contractors who are members of BIFSA and SAFCEC responded to this survey to determine the influence of clients on contractor health and safety.

11.3.1 Table 4 schedules the project priorities of clients as perceived by contractors. The environment, and health and safety were identified least and second least frequently respectively.

Aspect	Priority Ranking (%)				
	Very	Fairly	Not	Don't know	Total
Cost	90,1	5,6	0,0	4,3	100,0
Environment	11,6	63,3	18.8	7,3	100,0
Health AND safety	25,7	45,7	22,9	5,7	100,0
Productivity	46,4	27,5	23,2	2,9	100,0
Quality	90,0	5,7	1,4	2,9	100,0
Schedule	66,2	25,0	0,0	8,8	100,0

Table 4: Client project priorities as perceived by contractors.

11.4 Project management practitioners (PMP) and general contractors (GC)

11.4.1 Relative to the aspects negatively affected by inadequate health and safety, the consolidated responses emanating from the surveys presented in 11.2 and 11.3 above are presented in Table 5.

Aspect	Yes Response (%)	
	PIMP	GC
Cost	72,3	81,2
Environment	66,0	58,5
Productivity	87,2	87,1
Quality	80,8	82,4
Schedule	57,4	-*
Client perception	68,1	77,6
Contractor image	-*	86,8

Table 5: Aspects negatively affected by inadequate health and safety.
* Not asked

12 Conclusions

Accidents result in fatalities, injuries, disease and damage to the environment and do not constitute project requirements.

The traditional project requirements of cost, quality and schedule are marginalised by inadequate health and safety and concern for the environment. The benefits of prioritising health and safety and the environment include reduced cost, enhanced productivity and quality, earlier completion and customer satisfaction.

13 Recommendations

Health and safety and the environment should be included as project parameters. Inclusion as project parameters implies that: they be considered during all phases of a project; procurement systems be suitably structured, and practices are implemented to engender health and safety and sustainability of the environment.

Project Performance and Conflict Avoidance: A front-end approach

T. Abdel Meguid and C. Davidson
IF Research Group, Faculté de l'amenagement, Universite de Montreal, Montreal, Canada

Abstract

Building construction projects tend to perform poorly; most run over budget, lag behind schedule, and often terminate in litigation before courts of law. In order to improve the performance of the building projects and to minimize claims (the two faces of the same coin), the strategic decisions taken up front by the building owner need to be improved. These decisions constitute the building procurement strategy; they establish the contractual framework for any project.

Different procurement strategies are now available for an owner when he or she wishes to select an approach to project delivery; each strategy is better suited for some aspects of typical clients' demands, whilst being weaker on others. In selecting a specific approach to procurement, very little attention is- paid to the likely effect of conflicts and their associated claims on the time and cost performance of the project.

This paper reports the findings of a research [1] undertaken within the IF Research Group to assess the impact of procurement strategies on conflict; jurisprudence is consulted for delay-related claims: their frequency, their dollar amounts, and the time lost in settling them. The root causes of time-related claims occurring under different procurement strategies are discussed.
Keywords: Building procurement strategies, claims, delays, project environment, project performance,

1 Introduction

Given the varied scenarios of project procurement strategies now available, selecting the best performing project *organizational* strategy still is, or should be, the highest priority for the building client. Because procurement strategies establish the framework for the various contracts betweenthe building owner and the members of the building team, it is hypothesized that the level of project performance is reflected - inversely - in the number and the extent of claims that arise. More specifically, this research examines claims arising from delays, and relates them to procurement strategies, particularly in instances where project time is found to be an important consideration for the building owner.

2 Project environment

For a long time, construction projects were managed and controlled according to rigid organizational structures based upon institutionalized roles. Modern organization theories such as contingency theory [2] and systems analysis [3] have established that project organizations need to be flexible, dynamic and responsive to the environment in which they operate.

A building project has three environments: the External environment which includes socio-economic considerations and particularly the contemporary concern for sustainable development in one form or another; the Industry environment or the overall state of the building sector, typically the linkage between supply and demand for man-made environment or building space; and the Internal environment which includes the specific constraints under which a building project comes to life, in other words, how the particular building process is organized and how efficient it is likely to be. It is well known that the elements of the building industry are diverse: owners - the demand side - with their different profiles, and architects, engineers, contractors, sub-contractors, suppliers and manufacturers - the supply side [4].

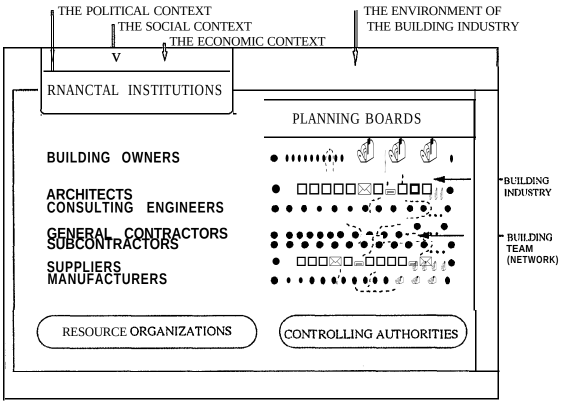

Figure 1: Building project as a temporary multi-organization [5]

The Building owner, although shown within the industry, belongs to a system of his own which is mostly external to the industry; he or she has functions and interests quite distinct from those of the industry, yet of necessity becomes closely involved with the building process* wherever a building is needed.

3 Project performance

Building project performance is defined as [1]:

> *" The effectiveness of the process, throughout its duration, in utilizing the available resources to satisfy the building owners' requirements and activities and to meet their constraints; and which results in the maximum collective benefit to all the participants without resorting to exploitation within the prevailing environmental conditions".*

The term "Performance" is thus understood to involve all aspects of the building process; these are productivity, timeliness, safety, quality and risk. These aspects are not mutually exclusive; each impinges on the others.

There is the wide-spread notion that for a project to be successful, it has to meet the owner's requirements of time, cost and quality. This view only reflects the short-term objectives of the team that is responsible for the project whilst neglecting the long-term objectives of each participating task-organization as it strives to survive in the marketplace. As result, a situation that requires joint decision-making is transformed into a kind of contest to claim greater bargaining powers. This situation is known, in management circles, to be an incubator for "inter-organization conflict", where inter-organizational conflict is manifested in disputes, which if remain unsolved, lead to claims. Claims are cumbersome to projects and affect inversely their performance.

To study the performance of different procurement strategies, one can explore the inherent problems and identify the root causes of inter-organizational conflict. Furthermore, it is logical to examine how they are reflected disputes and claims.

4 Claims and delays

There is abundant evidence in the literature concerning the severity of construction claims. According to Statistics Canada [6], about $94 billion have been spent on construction projects in 1993, which amounts to almost 13.5% of the Gross Domestic Expenditure. Based on the Rose report [7], a 20% increase in project cost can be attributed to claims; this means that the cost of claims alone amounts to approximately $18.8 billion - up 75% from 1990.

Goldsmith [8] defines a ***claim*** as "the demanding of something rightfully due to one". ***A contractual claim*** [9] is a written notice from either party to the contract (owner or contractor) to the other party requesting a relief (i.e. an extension of time or additional payment) due to unforeseen conditions, changes to the work, or interpretations of the contract.

---

*). In this paper, the term "building process" is used to describe the whole process from perception of the need to the occupancy of building by the owner [Davidson, 1988].

According to Bramble and Callahan [10], ***delays*** are defined as “the time during which . some part of the construction project has been extended or not performed due to an unanticipated circumstance”. Construction claims due to delays are among the most complicated and difficult to analyze; sometimes they overlap with others and are then known as concurrent delays. Determining the *origins* of each delay and its impact on the project, and, even more importantly, the *responsibility* for the delay, can easily lead to conflict and thence to claims. According to Rubin et al. [11] delays can be classified as:

i- Excusable delays, (unforeseen by the contractor); they can be either Compensable (caused by owner), or Non Compensable (Force majeure);

ii- Non Excusable delays (caused by contractor or sub-contractor); the owner is entitled to delay damages.

However, when claims arise, the need to resort to such extreme action as litigation or arbitration demonstrates a *failure of* the contractual process. Any attempt to control this process should use the “frontal navigation” approach, setting the control from the outset and, hopefully, eliminating undue problems along the way. One way of doing just that is to select an appropriate procurement strategy that is associated with minimum delays and disruptions.

5 Research methodology

One hundred and twenty one cases of litigated time-related claims were analyzed. Only ***litigated, excusable and compensable delay claims*** were considered since they represent the worst case scenarios, are documented and traceable, represent facts-based judgements, are not biased by subjective opinions and have a direct impact on the project time and cost.

The procurement strategies adopted for the cases were classified according to Masterman’s [12] categorization [separated and co-operative (or “traditional”) procurement strategy (62 cases), integrated procurement strategy (47 cases) and management-oriented procurement strategy (12 cases)]. Other variables were identified: the type of owner procuring the project, the type of contract, the type of building, the time the project was delayed (expressed as a % of the planned duration of the project), the claimed amount, the awarded amount (expressed as a % of claimed cost to the initial project budget and a % awarded to initial project budget) and the trial time (time before the court decision, expressed as a % of the planned duration of the project).

Causes of claims were identified and grouped into three main categories that coincide with inter-organizational conflict-inducing factors (domain consensus, availability and access to information, and coordination). These causes have been found to be deterministic of the performance of the building process [13], thus enabling us to link claims to the inter-organizational conflict-inducing factors and thence to the performance of the building process.

A survey of all projects in the Montreal Metropolitan area procured during a given period was used as a control group.

6 Research findings

6.1 Claims occurrences

The *separated and co-operative* procurement strategy still appears to be the preferred strategy for public owners in procuring building projects and has a lower occurrence of claims than the other two procurement strategies. This is not surprising considering that it is the one which has been used the longest and that contract documents have been fine-tuned and standardized for its usage. The private owners also appear to have mastered the separated and co-operative procurement strategy and face even fewer claims under this strategy than public owners.

While the *integrated* procurement strategy, with its main variant design-build, has been gaining much support lately and is being presented as the panacea to all the problems of the construction industry, *our findings prove the opposite.* Both public and private owners have a high incidence of claims under this procurement strategy.

The *management-oriented* procurement strategy also appears more often in claims cases than its usage.

6.2 Claims outcomes

The *separated and cooperative* procurement strategy proved to be the best strategy in terms of all the claims outcomes for the private owner while being the second best strategy in terms of all the claims *outcomes* for the public owner (Table 1 and Table 2).

Table 1: Consequences for *public owners* under different procurement strategies (from the owner's point of view)

PROCUREMENT STRATEGY	% Time Overrun			% Claimed to Budget			% Awarded to Budget			% Awarded to Claimed			% Trial Overrun		
	Low	Medium	High	Low	Medium	High	Low	Medium	High	Low	Medium	High	Low	Medium	High
Separated and cooperative Strategy		▒			▒			▒			▒			▒	
Integrated Strategy	■			■			■					▒	■		
Management-Oriented Strategy			▒			▒			▒	■					▒

Table 2: Consequences for *private owners* under different procurement strategies (from the owner's point of view)

PROCUREMENT STRATEGY	% Time Overrun			% Claimed to Budget			% Awarded to Budget			% Awarded to Claimed			% Trial Overrun		
	Low	Medium	High	Low	Medium	High	Low	Medium	High	Low	Medium	High	Low	Medium	High
Separated and cooperative Strategy	■				▒		■			■				▒	
Integrated Strategy		▒		■				▒			▒				▒
Management-Oriented Strategy			▒			▒			▒			▒	■		

For the public owner the *integrated* procurement strategy generally proved to be the best strategy in terms of all the claims outcomes. The *management-oriented procurement strategy* generally proved to be the worst strategy in terms of all the claims outcomes for both the public and the private owners.

A synthesis of the consequences for each type of owner under each of the three families of procurement strategies is shown in Table 3.

Table 3: Overall performance of the different procurement strategies, from the owner's point of view

PROCUREMENT STRATEGY	PUBLIC OWNER						PRIVATE OWNER					
	Claims Occurrence			Claims Outcomes			Claims Occurrence			Claims Outcomes		
	Low	Medium	High	Low	Medium	High	Low	Medium	High	Low	Medium	High
Separated and cooperative Strategy	■				▒		■			■		
Integrated Strategy			▒	■					▒		▒	
Management-Oriented Strategy		▒				▒		▒				▒

An examination of the synthesis shown in Table 3 indicates that there is a divergence between the occurrences of claims and their outcomes (e.g. the public owner under the integrated procurement strategy has a high claims occurrences but' has low claims outcomes). This suggested that an in-depth study of the root causes of claims would be useful.

6.3 Causes of claims

Twenty-two causes of claims were cited in the 12 1 claims cases in 241 instances (sometimes there were more than one cause per claim). Based on the factors in organizational design theory that were found to be conflict-inducing in multi-organizations, and were proven to be deterministic to the performance of the building project [13], the causes of delays were grouped into three main categories:

1. **Scope of the project (or domain consensus):** 5 causes of claims (changes in scope of work, changes of specifications by A/E, differing site conditions, misinterpretation of documents by A/E and excessive interpretation of documents) - evenly distributed among public and private owners (13 instances each) - were cited under this category in 26 instances;
2. **Availability and access to information:** 9 causes of claims (ambiguous documents, faulty specifications, incomplete documents, late approvals, late documents, late issuance of design documents, late rectifications, untimely and uncoordinated change orders and untimely design revisions) - 92 instances for public owners and 50 instances for private owners - were cited under this category in 142 instances;
3. **Coordination (or interdependence of tasks):** 8 causes of claims (lack of coordination, restricted site and interference, delayed site access, acceleration,

winter work, lack of site supervision, disruption by A/E and payment delay) - 46 instances for public owners and 27 instances for private owners - were cited in 73 instances.

A detailed analysis of the different causes of claims under the three families of procurement strategies and the two types of owners (public and private) revealed:

In the <u>scope of the project</u> category, all types of owners run into more problems when integrated and management procurement strategies are adopted, particularly regarding (i) changes in scope of work, (ii) differing site conditions and (iii) excessive interpretation of specifications;

In the <u>availability and access to information</u> category, all types of owners face numerous claims stemming from untimely and uncoordinated change orders; problems also arise from faulty or late documents in the traditional and integrated approaches to procurement; this category of causes underline the majority of claims cases - 58.92%;

In the <u>coordination</u> category, private owners fare better than their public counterparts, but for both, lack of coordination and restricted site and interference cause a number of problems.

7 Conclusions

The discourse concerning delay-related claims is not very different from that on inter-organizational conflict and the performance of the building process from the point of view of the availability and access to information. A systematic effort to co-ordinate information management appears to be a prerequisite for success, and particularly for the successful introduction of innovation or changes in the building process and for the improvement of the performance of the process itself.

Meanwhile, our findings point to the consequences (in terms of claims) of the constraints within which public sector owners operate. They also throw an unexpected light on the likelihood of all types of owners running into trouble when non-traditional procurement strategies are adopted, suggesting the need to fine-tune the practicalities of these strategies.

Surprisingly, the management-oriented procurement strategy proved to be the worst strategy for both types of owners. The introduction of a new party (the construction manager) into the traditional project team appears to pose a problem of integrating another party into the classic “team” of designers and constructors.

The separated and co-operative (or traditional) procurement strategy still is the preferred strategy and has less occurrences of claims with less impact on time and cost of the project. Innovative procurement strategies proved to be in a bad position compared to the traditional procurement strategy. The possible explanation of this result is that the innovative procurement strategies (integrated procurement strategy and management-oriented procurement strategy) are relatively new, comparatively untried and obviously require further development in order to iron out contractual and other kinds of problems.

While the choice of a procurement system cannot be based merely on the potential to minimize unhealthy disputes and litigation, this criterion can be incorporated as one of the criteria to be considered when selecting an appropriate procurement system.

ATTITUDES TO UK CONSTRUCTION PROCUREMENT SYSTEMS FOR REFURBISHMENT WORK

C. 0. Egbu
Building Research Establishment, Garston, Watford, England, UK

Abstract
This paper reports some of the findings of a study on construction procurement systems for refurbishment works which involved **86** postal questionnaires completed by key personnel from client's representatives (architects, quantity surveyors), contractors and other consultants from specialist and general UK refurbishment organisations. This was augmented by 10 semi-structured interviews conducted with directors of construction refurbishment organisations. The study addresses, ***inter-alia,*** the frequency of use of procurement systems for different sizes and types of refurbishment projects; appropriateness of different procurement systems for refurbishment works, and the variety of factors affecting clients' choice of procurement systems for refurbishment works. It is suggested that the majority of refurbishment projects are still procured via the Traditional route, the main reasons being price competition and price certainty. Similarly, the inherent risks associated with refurbishment works are not given due consideration in the choice of procurement route. There is little, if any, authoritative guidance documentation on the selection of appropriate construction procurement systems for refurbishment works, yet evidence from this study suggests that there is an urgent need for guidance documentation. The challenge, therefore, is for the industry to produce guidance documentation on selection criteria and practices for procuring works in this very important sector of construction - the refurbishment sector.
Keywords: Contract, construction procurement system, professional attitudes, refurbishment works.

1.0. **Introduction**

Few will argue that matching the right procurement system with the right type of project to be carried out by competent professionals will benefit the client, the consultants and the construction industry as a whole. Construction procurement routes have received a wide coverage in the literature [1]. Similarly, studies have been conducted in order to improve the industry's awareness in selecting construction procurement systems [2]. In the main, however, these studies have been on new build works with very little attention being given to the refurbishment sector. In looking into the future direction of the UK project procurement, Hamilton (1990)[3] suggests that the client body is not yet fully satisfied with the services offered by the industry, and that there are likely to be more variations in the basic range of procurement systems. Hughes (1992)[4] is also of the view that 'the construction industry and its clients are still trying to sort out reliable methods of procuring construction'.

In his article entitled "Contractual terms for property maintenance and refurbishment projects: Their development, selection and interpretation", Robinson (1990)[5] argued that the standard form of contracts developed for new build applications have little relevance to the complexities and diverse nature of works on existing shells'. A thorough review of literature in the general areas of refurbishment [6, 7] would suggest that there is little or no authoritative guidance documentation on selection criteria and practices for procuring construction refurbishment works.

2.0. Methodology

The carrying out of the study was premised by the fact that a thorough literature review revealed that little or no empirical study has been conducted in the UK, in the past five years, in the area of construction procurement systems for refurbishment. It was therefore important to understand the current industry's attitudes to procurement systems for refurbishment works.

The study on which this paper is based was conducted between February and August 1997. From 250 postal questionnaires sent out, a total of 86 usable questionnaires from building contractors, architects, quantity surveyors, building surveyors and other consultants were received. Table 1 presents a frequency distribution of the postal questionnaires received by types of construction organisations. In addition, 10 ethnographic interviews with directors of construction refurbishment organisations and archive documentation obtained from construction organisations form the database for the study. For this paper, however, only some of the information derived from the quantitative data will be explored.

Types of Organisation	Number	Percentage (%)
Building contractor	45	52.3
Architects	23	26.7
Quantity Surveyors	9	10.5
Building Surveyors	4	4.7
Other Consultants	5	5.8

Table 1: Respondents to postal questionnaire by type of organisation (N = 86)

3.0. The Nature of Refurbishment Works

In this paper, refurbishment means such works as improvement, adaptation, upgrading, renovation, rehabilitation, modernization, conversion, retrofit, and repair; carried out on existing buildings for a variety of reasons. This definition, however, excludes works carried out on a routine basis such as cleaning, painting and decorating, and also emergency maintenance work.

In 1970, the repair and maintenance sector which accommodates refurbishment works accounted for £1109m (or 22.46%) of the total UK construction output. By 1996 this figure had increased to £21087m (or 42.32 % of total construction output). Despite the growth and increasingly recognised importance of refurbishment, only a meagre amount of empirical studies have been conducted in the management domain and in the areas of construction procurement systems [6, 8]. In their review of what has been published in the international journal - Construction Management and Economics in the ten year period between 1983 and 1993, Betts and Lansley (1993)[9] noted that ' . . . given their importance in developed construction markets, the use, maintenance and refurbishment phases have received little attention".

Yet, some writers have argued that refurbishment work is less predictable than new-build work, with a higher level of risk and uncertainty [8, 10]. It has also been shown that tender bids for refurbishment works are more variable than new build works [11, 12]. There is also a higher incidence of variation orders in a refurbishment contract, and a tendency for the job to expand to meet the budget [13]. There are others who have suggested that refurbishment processes are more difficult to manage than new build works [6, 10, 14]. It is therefore important that some attention is levelled at the selection criteria and practices used for procuring refurbishment projects.

4.0. Construction Procurement for Refurbishment Works

Construction procurement in the context of this paper means the framework within which construction work is brought about, acquired or obtained.

The Royal Institution of Chartered Surveyors [15] in their publication entitled "Refurbishment and Alteration Work", noted that '... traditional bills of quantities prepared in accordance with Standard Method of Measurement, are generally not suitable for the average refurbishment project. Similarly, Hakman (1975)[16] has argued that the repair and alteration work '... have their own special problems and conditions which need to be addressed in the preparation of the bills of quantities '.

Fellows *et al* (1985)[17] are also of the view that a more participative and flexible approach to contractual arrangement and procedure are needed. Ferry and Brandon (1991)[18] advised that '... the uncertainties of refurbishment work mean that it will be almost impossible and, certainly inadvisable, to undertake the [refurbishment] project on the basis of lump sum competitive tenders for the works, and other more collaborative methods of procurement will have to be used; either cost-plus or some form of management contracting.

The meagre amount of empirical studies conducted in the areas of construction procurement for refurbishment works would appear to have been conducted over 5 years ago. The UK construction industry is a changing industry, and so is the refurbishment sector [8]. It is therefore important to understand the current views of the refurbishment sector on construction procurement systems. This is important, at least, for two main reasons, Firstly, for policy makers in construction and those involved in strategic management within construction organizations. Secondly, it will provide some useful information for the development of appropriate and authoritative guidance documentation for selecting procurement systems for refurbishment works.

5.0. Study Results and Discussions

This study sought to ascertain the current frequency of use of construction procurement systems for refurbishment works. The study revealed that four main procurement routes are used for refurbishment works. These are presented in Table 2 in decreasing frequency of use.

An inspection of Table 2 reveals that almost 80% of refurbishment projects are procured through the Traditional form of procurement method. The study also shows that Design & Build is the next favoured form of procurement route. According to this study, only 3% of refurbishment projects are procured using the Management Contracting route. Although not analysed in this paper, the study also investigated the relationships between sizes of refurbishment projects, types of refurbishment projects and the usage of procurement systems. The study also sought to ascertain the underlying reasons behind the usage and selection of construction procurement systems for refurbishment projects.

Construction procurement systems	Frequency (No.)	Percentage (%)
Traditional	68	79.0
Design & Build	9	10.5
Construction Management	6	7.0
Management Contracting	3	3.0

Table 2: The frequency of use of procurement systems

The selection criteria from the views of the 86 respondents who participated in the questionnaire phase of the study are listed in Table 3 in decreasing level of importance for the most used procurement systems.

Rank	Traditional	Design & Build
1	Price competition	Risk avoidance and responsibility
2	Price certainty	Price certainty
3	Quality level	Quality level
4	Risk avoidance and responsibility	Speed of construction
5	Speed of construction	Price competition
6	Control of variations in the project	Control of variations in the project
7	Reserving client's right to alter specification	Clarity of client's contractual remedies
8	Dealing with complexity of projects	Involvement of client in construction process
9	Involvement of client in construction process	Reserving client's right to alter specification
10	Familiarity of procurement system	Dealing with complexity of projects
11	Clarity of client's contractual remedies	Familiarity of procurement systems
12	Separation of design from management	Separation of design from management
Rank	**Construction Management**	**Management Contracting**
1	Quality levels	Speed of construction
2	Reserving client's right to alter specification	Risk avoidance and responsibility
3	Control of variations in the project	Price certainty
4	Dealing with complexity of projects	Control of variations in the project
5	Speed of construction	Quality level
6	Price certainty	Reserving client's right to alter specification
7	Price competition	Involvement of client in construction process
8	Risk avoidance and responsibility	Clarity of client's contractual remedies
9	Involvement of client in construction process	Dealing with complexity of projects
10	Clarity of client's contractual remedies	Separation of design from management
11	Familiarity of procurement system	Familiarity of procurement systems
12	Separation of design from management	Price competition

Table 3: Criteria for selecting construction procurement systems for refurbishment works

An inspection of Table 3 which is data from an aggregate level indicates that the relative ranking of selection criteria differs from one procurement system to another. For example, price competition and price certainty were cited by the respondents in this study as the two most important criteria for selecting the Traditional procurement route, whereas the two most cited criteria for choosing management Contracting for refurbishment works were speed of construction and risk avoidance and responsibility. Interestingly, familiarity and knowledgeability of procurement options was rated very low as a criterion for selecting procurement systems. It is therefore important that any authoritative guidance documentation for the selecting construction procurement systems for refurbishment projects takes due cognizance of the necessary weighting factors associated with types of procurement systems, the views of different groups of construction professionals associated with refurbishment works, sizes, types and nature of refurbishment projects.

The study also sought to ascertain the extent to which there is an urgent need for a guidance documentation for the selection of appropriate procurement system for refurbishment works. To this end, the vies of participants to the questionnaire phase of this study were sought on the extent to which they agreed or disagreed on the need for a appropriate guidance documentation, Table **4** presents the result of this study.

	Frequency	Percentage (%)
Strongly Agree	**22**	**25.6**
	42	**48.8**
Not Sure	17	19.8
Disagree	**4**	**4.7.**
Strongly Disagree	1	1.2

Table 4: Degree of agreement for guidance documentation on construction procurement for refurbishment works

An inspection of Table 4 reveals that whilst over 74% of respondents in this study either agreed or strongly agreed on a need for a guidance documentation, just under 2% showed strong disagreement. The challenge for the industry, therefore, is to produce an authoritative guidance documentation for refurbishment works that takes account of the vagaries of refurbishment processes.

6.0. Conclusions and Recommendations

A recent study on construction procurement systems for refurbishment work has been conducted. It shows that the Traditional form of procurement, Design & Build, Construction Management and Management Contracting are the favoured forms of contract for refurbishment work. Whereas as almost 80% of refurbishment works are procured through the Traditional route, only about 3% of refurbishment works are procured by Management Contracting. Twelve factors have been identified that impact upon the selection of procurement systems for refurbishment works. These include: price certainty, importance of these factors in the selection of procurement options differ from one procurement system to another.

There is little or no authoritative guidance documentation on selection criteria and practices for procuring refurbishment works, yet this study has show an overwhelming need for one. The challenge, therefore, is for the construction industry to produce one, Such documentation should be based on appropriate weighting factors which take due cognisance of different types of procurement systems, the views of different professionals associated with refurbishment works, sizes, types and nature of refurbishment works.

Environmental risk assessment of private finance initiative projects

A S Akintoye
Department of Building and Surveying, Glasgow Caledonian University, Glasgow, United Kingdom

Abstract

The Private Finance Initiative (PFI) is a recent procurement strategy in the UK for bringing the private sector's fmancing ability, management skills, and expertise into the provision of public sector facilities and services. It is intended that this will promote significant risk transfer to the private sector and achieve value for money in the provision of assets. The Government has identified six principal risks relevant to PFI schemes which must be allocated to the appropriate parties. These include environmental risks as part of regulation and legislation principal risk.

Under PFI, the private sector has more responsibility than before to attend to changing environmental risks regulations, laws and directives from the European Union, UK Acts of Parliament and Organisation for Economic Co-operation and Development (OECD) policy. The PFI consortium (contractors, lenders, investors) have to date shown little regard to environmental issues associated with PFI schemes. It is argued that this could be as a result of the structure and culture of the construction industry which approaches risk in a fatalistic or reactive way rather than proactive or holistic. It is reckoned that there is need for a more satisfactory assessment of the costs of all environmental risks at all stages of contract negotiations and operation. The basic steps in environmental risk assessment in the processing industry sector are risk identification, risk evaluation, risk prevention and loss control, and risk fmancing and effective monitoring. The paper presents some techniques currently being used at all stages of environmental risk assessment in the processing sector for adoption by the construction industry.

Keywords: Environmental risk, environmental risk impact, private finance initiative, risk analysis techniques, sustainable development, environmental legislation.

1 Introduction

One of the major changes occurring in the decade is that businesses have begun to realise that the natural environment is an important part of the business environment [1],[2]. People are now beginning to show more concern than before for their environment in terms of health, safety, global warming, environmental degradation, threats to Earth's ozone layer etc. The level of community concern and outrage about their environment is unprecedented.

Achieving high quality environmental performance and taking a proactive position is becoming a factor for business not just for future commercial success but also for survival. The construction industry, like other sectors of the economy, faces much more environmental scrutiny and regulations, which implies that the industry must take more responsibility for environmental protection. Further, the integration of environmental concerns into sectoral decision making is now considered a key to improving environmental performance and moving towards sustainable development. Within the European Community, authority for environmental protection which is contained in the Treaty of Rome is based on the need to protect the environment, human health and natural resources [3].

Environmental risk assessment is applicable in cases where the use of land, building or facilities causes disturbances to the environment through air pollution, noise, vibration, intense lights etc. Environmental risks can differ depending on the sector of the economy. For example, Wilson [4] looks into this from a chemical processing perspective in terms of the presence of substances such as asbestos, chlorofluorocarbons, polychlorinated biphenyls etc and the impact the associated risk could have on the value of stakeholders interests (e.g. property owners, financial institutions, occupants, neighbours, regulators etc.). Root [5] looks at environmental risk in terms of risks associated with the transactional environment (consisting of actors such as customers, suppliers, banks, competitors etc. that a company interact or transacts with in a direct way) and the contextual environment (political, economic, technological, social-cultural etc.).

In general, significant damage to the environment is caused by three business sectors namely the municipal sector, the construction sector, and the processing sector [6]. In the construction industry environmental damage could take the form of environmental impact from blasting operations, air pollution caused by demolition or painting work etc. Pasquire [7] identifies environmental issues in construction including environmental legislation affecting the UK construction industry. The report concludes by calling for more research to provide qualitative and quantitative data and develop formal procedures for the procurement and management of environmental issues in construction.

This paper presents on-going environmental issues research which forms part of a larger research project on the Private Finance Initiative being undertaken at Glasgow Caledonian University.

2 Statutory Sources of Environmental Risks and Financial Exposure

Companies in the UK are now subjected to a wide range of environmental laws, regulations and directives; the majority of which emanated from the European

Community / European Union (EC/EU). Writing in 1989, Johnson and Corcelle [8] observed that over 100 legislative acts relating to all aspects of the environment has been adopted by the EC. There are currently more than 33 items of EU environmental legislation which can be grouped into seven categories: General Environmental Policy Regulations; Air; Chemical, Industrial Risks and Biotechnology; Nature Conservation; Noise; Waste and Water [9].

The 1990s, in particular, have witnessed greater emphasis on the environment within EC/EU policy making with the introduction of the concept of sustainable development in the 5th Environmental Action Programmes [10]. The 5th EAP differs from its predecessors in that it requires a longer term focus in terms of environmental objectives, seeks a greater understanding of the nature of risks to the environment, and advocates a mix of instruments designed to achieve policy objectives.

CIRIA [11] and Pasquire [7] have both listed the main UK Acts of Parliament affecting the UK construction industry. Some of these are in response to the EC/EU environmental legislations and directives [4]. Also the UK is responsible to the Organisation for Economic Co-operation and Development (OECD) environment policy which is monitored through the OECD environmental performance reviews. The main theme of the review is the reduction of the pollution burden, conserving nature and integrating environmental concerns in economic and sectoral decisions [12]. A full discussion of the implications of environmental legislation for the property and construction industries can be found in Lizieri *et al* [13]

In terms of financial risk exposure from short and long term environmental issues, Baker [14] recognises some potential sources namely: major environmental capital expenditures; increased costs associated with greater commitment to environmental management programmes; financial needs for acquisitions and divestitures arising from environmental liabilities; and reserves for adverse environmental-related contingencies.

A major financial risk leading to environmental capital expenditure is the possibility of a company being required to commit substantial funds to comply with environmental laws and regulations [15]. Company-caused environmental problems could lead to litigation including tort liability, class action suits, and victim compensation for personal injury or property damage based on the principles of strict, joint and several liability [14]. It is reckoned that financial risk exposure due to environmental issues deals with costs associated with environmental problems prevention, restoration and compensation [16].

In respect of construction, recent events such as the Manchester Airport runway development have shown that financial risk exposures due to environmental issues are from time- and cost-overruns because of delays caused by environmental lobbyists and interest groups. This is apart from costs associated with compliance with environmental laws and regulations for prevention, restoration and compensation.

3 Overview of PFI

The Private Finance Initiative (PFI) is, currently, the Government's main innovative instrument for the delivery of public services in the UK. It presents the public sector with the opportunity to procure services, or buildings and infrastructure, while leaving the risks of asset and infrastructure ownership and maintenance with the private sector.

The two fundamental requirements of the PFI are that the public sector must secure value for money; and there must an appropriate transfer of risk to the private sector.

A major element of the PFI is that the consortium responsible for the provision of the PFI can adopt an innovative design, construction, and operation approach. For example Design, Build, Finance and Operate (DBFO) and Build, Operate and Transfer (BOT) leading to fundamental improvements in quality, cost and time of delivery of public infrastructure [17]

Principal risks relevant to PFI schemes which are expected to be transferred to the private sector are design and construction risk (with particular reference to cost and time); commissioning and operating risk (including maintenance); demand for volume/usage risk; residual value risk; technology/obsolescence risk; and regulation and legislation risk.

Environmental risk is part of regulation and legislation principal risk. Government bodies, project lenders, investors and developers all have a greater degree of corporate responsibility than before, for appropriate consideration to environmental matters and compliance with environmental legislation and guidelines when considering major project development. Under PFI it is expected that the consortium will comply with all environmental laws, directives and regulations. Such directives will include those relating to air pollution control, water pollution programme, waste management, etc.

The EC June 1985 [18] directive on environmental impact assessment, for example, requires an evaluation of potential environmental 'impacts of proposed projects. The Directive requires an environmental assessment of major public and private projects which takes into consideration the nature, size, and location of the proposed project [3].

Under the PFI procurement method, compliance with EC directives, for example, becomes the responsibility of the private sector responsible for providing the public sector services. It becomes the responsibility of the PFI consortia to consult with the local community and organisations such as "Friends of the Earth" at the feasibility stage of the project to accommodate their views or negotiate the process in order to avoid project delays, additional costs and bad publicity. As part of the PFI deal, financial institutions (project lenders) are expected to conduct environmental assessments of commercial transactions in order to control risk exposure from environmental liability.

In summary, the PFI places more responsibility on the private sector to carry additional risks including environmental risk associated with public sector schemes.

4 Innovation and Sustainable Development through PFI procurement

Sustainable development is a major concern to the world and formed the basic theme of the report 'Our Common Future' produced by Brundtland commission for the United Nations. [19]. The report described sustainable development as 'development that meets the needs of the present without compromising the ability of the future generations to meet their own needs'. The report further recognised that the environment is where we live and development is what we all do in attempting to improve our lot within that abode, and as a result the two are inseparable.

Sustainable development in construction procurement is about more concern for environmental issues at various levels of decision making within the construction process including budgeting, design, construction, operation and maintenance.

Traditionally, the risk associated with environment issues for public sector projects is borne by the government.

Under PFI, the public sector is expected to produce a business case, or proposal for the scheme. This specifies both the functional and performance or output requirements for the scheme. The private sector then transforms this to a service design which should meet the performance requirements specified by the client. The consortium is expected to operate, effect repairs to and maintain, the asset throughout the contract period to an agreed quality standard and ensure continuity and quality of service of the asset.

Because the PFI consortium takes control of the design, construction, operating and financing of the scheme, there is opportunity to introduce innovation that will ensure sustainability of the service provision. The consortium, at the design stage, has the opportunity to assess the environmental quality of the scheme and the consequent potential for reducing environmental damage by improving the design.

The PFI procurement method provides the consortium with a greater opportunity to assess the environmental quality of a scheme at the design stage. The overall implication of the environmental assessment at this stage is that the life cycle of the scheme can be considered, including environmental implications and sustainability

5 Environmental Risk Assessment Process

The basic steps involved in environmental risk assessment are risk identification, risk evaluation, risk prevention and loss control, and risk financing and effective monitoring [20], [21].

5.1 Risk identification

This is about identification of the total impact of a project and its effect not only on the environment but also on the local community and the nature conservation interests. A risk matrix could be produced which identifies crucial environmental issues and assesses their potential impact. This may include identification of existing environmental problems about the site and adjoining property through a record search, site inspection and report.

Techniques of risk identification used in processing sectors can be classified into three categories namely: intuitive, inductive and deductive. These techniques are facilitative tools to maximise the opportunity of identifying all the risks in a particular system, facility, or product. Intuitive method includes brainstorming. Inductive methods include checklists; preliminary hazard analysis such as hazard and operability studies (HAZOPS); human error analysis such as failure modes and effects criticality analysis (FMECA) and fault tree analysis. Deductive techniques include hindsight and event tree analysis.

- HAZOPS are structured brainstorming techniques carried out by a multi-disciplinary team of experts, useful for identifying potential hazard in buildings and facilities at all stages of the design and development.
- FMECA is carried out by an individual expert with a thorough understanding of the system using a step by step procedure to identify failure modes or design weaknesses and the criticality of the consequences of failure.

- Fault tree analysis demonstrates an understanding of how the failure could occur in the system and what effect modification might have by looking through all the branches of the system.
- Hindsight is based on learning experiences from techniques of investigation and analysis undertaken in the past.
- Event tree analysis shows the consequences of a particular fault identified from the fault tree analysis resulting in elimination of those paths which lead to the more severe consequences.

5.2 Risk evaluation and quantification process

This is about the generation of quantitative information on the environmental risks associated with schemes. It involves tools and techniques for quantifying potential environmental loss exposures and cost, in the area of environmental compliance, auditing for effective waste reduction and minimisation. Quantification deals with assessing the probability of the failure occurring and the consequences if it does, while evaluation deals with tolerability and acceptability of risks.

Techniques of risk quantification include reliability estimation using reliability block diagrams and network analysis, fault trees, event trees, computer modelling such as Monte Carlo simulation and expert systems. Techniques of risk evaluation include:

- Risk criticality matrices which are based on two by two matrix indicating the various criticality levels. Evaluation exercises are undertaken by noting the relative position on the matrix of the variously identified risks, prioritising and establishing the acceptability threshold, through the ‘as low as reasonably possible’ (ALARP) principle.
- Cost effectiveness is based on budget; the evaluation techniques depend on the lowest risk which can be achieved within the budgetary constraints.
- Cost-benefit analysis evaluation techniques are guided by whether the cost of the risk reduction measure is less than the value of the benefit achieved, in which case the reduction measures should be implemented.

5.3 Risk prevention and loss control

This includes a programme of risk prevention including pollution prevention, risk communication and crisis management (i.e. emergency planning e.g. chemical spillage).

5.4 Risk financing and effective monitoring

This involves an evaluation of an array of risk transfer and risk retention methods for safeguarding corporate income through commercial insurance, risk retention groups and captive insurance companies [5].

6 Environmental risk ranking and risk analysis techniques in construction

Risk strategy is governed by the number of different types of risk an organisation considers, the likelihood of their occurrence, and the likely severity of their impact [22]. Obviously, PFI schemes have many risks, including environmental, for the consideration of the consortium. Although the likelihood of occurrence of environmental risk may be low, the likely severity of impact is usually high (see section 2).

Table 1 based on the research survey of 42 respondents (government departments, contractors and financial institutions) that are involved in PFI Projects [23] shows that environmental risks were ranked 16th out of the 26 listed risk factors that the public sector requires to significantly transfer to the private sector.

Table 1: Respondents ranking of PFI risk factors

RISKS	Respondents			
	All	**Lenders**	**Contractors**	**Clients**
Design Risk	1	10	1	5
Construction Cost Risk	2	6	2	6
Performance Risk	3	8	4	2
Risk of Delay	4	7	7	3
Risk of Cost Overrun	5	2	3	9
Commissioning Risk	6	5	17	1
Volume Risk	7	3	8	10
Operating / Maintenance Cost	8	13	9	4
Payment Risk	9	1	10	14
Tendering Cost Risk	10	9	6	17
Contractual Risk	11	15	5	11
Legal Risk	12	12	11	19
Market Risk	13	11	14	16
Residual Value Risk	14	14	16	12
Planning Risk	15	19	13	18
Environmental Risk	16	23	15	8
Safety Risk	17	20	21	7
Financial Risk	18	18	12	22
Credit Risk	19	4	25	24
Possible change in government	20	16	20	20
Project Life Risk	21	22	24	15
Changes in European legislation	22	26	19	13
Development Risk	23	24	18	21
Bankers Risk	24	17	23	26
Debt Risk	25	21	22	25
Land Purchase Risk	26	25	26	23

However, the risk factor is important to the clients and this has been ranked 8th. The high ranking of risk factor by the government department would suggest that it is important that the risk is transferred to the private sector in view of the need to comply with both the EC regulations and directives and the OECD on environmental protection. Recent cases of DBFO schemes delayed due to protests by ‘anti-roads activists’ and ‘Friends of the Earth’ include the M3 Motorway extension (Newbury bypass scheme) [24]. The demonstration caused cost and time overruns to the public sector and tended to reinforce the need for the risk involved to be transferred to the private sector.

Although contractors and project lenders have ranked environmental risk 15th and 23rd respectively, this may tend to suggest that either they do not wish the risk to be transferred to the private sector, or they underestimate it, or they do not feel that they have more responsibility for environmental risk under PFI procurement, perhaps even they believe they are not capable of mitigating this risk or they lack expertise in risk analysis techniques required in dealing with environmental risks etc.

Table 2, based on a research survey of UK contractors [25], shows a lack of expertise in generic risk analysis techniques. In the survey the respondents were asked to identify the techniques or methods of risk analysis they are familiar with, and ones that are being used by their firms for project risk analysis and management. The report shows that the use of risk analysis techniques by the responding firms is generally low in construction projects with the exception of Intuition/checklist. This method of risk analysis has been criticised because although it is possible to make a long list that is reasonably comprehensive, this approach gives little confidence that all risks have been identified [26]. The table also shows that most of the respondents are familiar with sensitivity analysis technique but the knowledge of advanced methods such as decision trees analysis, Monte Carlo simulation and subjective probability is low.

Table 2: Usage of techniques of Risk analysis (by per cent of the respondents)

Risk analysis methods	Respondent familiar	Use within Organisation
Risk premium	27	33
Risk adjusted discount rate	17	7
Subjective probability	17	23
Decision analysis		
Algorithms	3	0
Mean end analysis	7	0
Decision trees	27	13
Bayesian theory	7	0
Sensitivity analysis	53	53
Monte Carlo simulation	20	3
Stochastic dominance	0	0
Caspar	0	0
Intuition/checklist	77	77

The results show that many risk assessment methods such as Monte Carlo simulation (designed to provide quantitative estimates of the risk associated with a proposed action) are not used in main stream construction activities talk less of environmental risk assessment. These techniques are increasingly routine, for instance, in both the insurance and chemical industries, and are being frequently used by energy production and electric utility firms.

Overall the result of ranking environmental risk and risk analysis techniques in the industry suggested that the construction industry's risk management philosophy is fatalistic rather than holistic. According to Smallman [22] companies or industries following the holistic paradigm will generally tend to consider all types of risk facing them regardless of the likelihood and severity. Such companies or industries will also tend towards an overall policy of avoiding risks. Whereas the characteristics of fatalistic or reactive approach are found in the construction industry i.e. organisations rely largely on risk retention (accepting loss) and risk transfer (hoping that some other institution will bear the loss). The 'holistic risk management' or pro-active approach demand that risk must be avoided, prevented and reduced through strategic management including organisational learning, proven qualitative and quantitative risk assessments and risk forecasting [22].

7 Conclusion

The current responsibility of the private sector under the PFI demands that they review carefully their current practices in facility design, construction, operations and maintenance. Research to date shows that construction contractors have not taken seriously the demands of environmental laws and regulations on their business activities. There is no doubt that environmental matters constitute financial threat to construction business activities. Traditional procurement practices show that the responsibility for environmental issues could be transferred to the client. The current innovative procurement methods such as the Private Finance Initiative (e.g. DBFO, BOO, BOOT etc.) demand that the construction industry absorbs more risks, including those associated with the environment, as part of their business risk.

The construction industry, generally, shows some characteristics of the fatalistic approach to risk management with tendencies towards risk retention and transfer of construction business risk, including environmental risk, rather than proactive or holistic risk management that is associated with strategies leading to risk avoidance and loss control (risk prevention and limitation).

Although the construction industry has not shown enough competence in the use of risk analysis and management tools, techniques and methods, this paper identifies some proven techniques of environmental risk assessment that are in use in the processing industry sector that the construction industry can learn from. Also it is hoped that the framework for environmental risk assessment presented in this paper will stimulate both theoretical and empirical research that will strengthen our understanding of environmental issues in construction.

Environmental Concerns V's Commercial Reality - Who Really Pays for Construction Waste?

Stephen Emmitt and Christopher A. Gorse
Faculty of Health and Environment, Leeds Metropolitan University, Leeds, UK

Abstract

The procurement team's approach to construction, and more importantly individual participants' approach, will affect the contribution made to the built environment: buildings not only use scares resources in their construction but also generate a great deal of waste during the construction phase, waste which has to be disposed of and could be reduced considerably. This paper presents a view from an architect (client briefing and design phase) and a construction manager (building phase) of the way in which waste is generated and subsequently disposed of during a building project. Through a number of case studies the authors address the balance between financial and environmental concerns during procurement. The case studies, along with the authors' individual views help to illustrate the difference in culture between the design and construction phases in a buildings life. Although the case studies were not linked, there was a clear emphasis on cost, with environmentally responsible behavior closely linked to cost benefit. It was also evident that designers were looking to the site for improvements in waste control (outside of their control) and site agents were looking toward the designers for more to be done at the design stage (outside their control).

The concept of individual responsibility within the temporary procurement team is an area for further investigation and research. Furthermore, it appeared that one of the main barriers to reducing waste on site was one of existing values and a lack of effective communication between parties. Control of construction waste should be seen as a continuing process at all stages in the life of a building, but the wide variety of participants, all with differing values, goals and responsibilities, such control is always going to be difficult. It is the social and structural issues that need to be addressed rather than issues of a technical nature, combined with communication between designer and builder - in short a re-assessment of building procurement for an environmentally responsible age.

Keywords; Communication; Individual responsibility; Land. fill tax; Temporary procurement networks; Waste management.

Introduction

Recent legislation, originating from a European Commission Directive requires the health, safety and welfare of a structure to be considered and costed (in terms of adequate resources) for the entire life of that structure. It is suggested, as a minimum, that the same consideration needs to be given to the waste disposal, and embodied energies of a building at feasibility stage so that the impact of building can be reduced. Although landfill tax increases, of £ 2 per tonne on inert material and £ 7 per tonne on biodegradable material, may help to reduce the amount of landfill and may lead to an increase in recycling of building materials, once a building is built both the volume and type of material is fixed within the structure until demolition and disposal. The disposal of the building is limited to what can be done with the materials and material types which were selected at design stage. Certain materials or composite materials are less easy to recycle or dispose of than others and paradoxically recycling of materials may demand more energy, possibly causing greater harm to the environment than reuse would justify. Consideration needs to be given to the possible reuse of the materials and the amount of waste in the event of demolition at the design stage. Thus developers and designers needs to consider production and demolition, as well as the building in use, when assessing its impact on the environment at an early stage in the procurement process if real reductions in building waste are to be achieved.

Competitive construction and the environment

The main argument for reducing and recycling waste has to be related to cost, since waste costs money [1]. Construction contractors have to balance cost against the environment. In a recent survey [2] when contractors were asked if they would use green products or materials, a significant number of the contractors added a note that "the cost would have to be equal or the client would have to be willing to accept the additional cost in using the eco-label products". A construction company will not stay buoyant unless it wins competitive tenders. The majority of the clients are in the business of selecting the most competitive contractors; balancing cost against the quality of company. Without doubt the image of a quality construction company may be built on an infrastructure of previous quality construction products, good safety records and possibly an environmental awareness. However, what is commercially the most competitive product or process may not be the most beneficial to the environment; there is an imbalance, it could be financially incorrect to select the cheapest product when the environmental costs are carried by others. Financial costs to the country, directly associated with environmentally unfriendly materials include;

- control and disposal of waste, landfill sites, incinerators.
- control of pollution to the ecological system correction measure where the environment is damaged.
- control of emissions, atmospheric pollution.
- research funded to investigate environmental problems caused by construction waste.

- energy costs

When products and processes eventually harm our environment so much that attempts are made to rectify the situation, the majority of the costs are picked up by tax payers, both now and in the future. What is happening is that those cheaper more cost effective processes and products, which do not consider waste management, are costing more. It is fundamentally wrong that a material is used from the other side of the globe, which uses more energy and packaging in transportation, when a comparable material is available in this country - there are clearly problems with the global economy. The cost of disposing discarded packaging is borne by individual countries, whilst the wasted energy and emissions affects the entire planet. In a survey [2] specifically targeted at developers in the construction industry, cost always took priority over any environmental issue. When considering factors effecting product selection, the recycling potential of the product, 'green factors' were given less consideration than cost, durability, whether the product had a British Standard, the appearance, previous use of the product and maintenance costs. Regardless of any environmental conscious image which clients, architects and developers wish to portray it is apparent that little effort is devoted to reducing the impact of the construction industry on the environment on an individual level. Designers, developers and contractors must be forced (encouragement is not enough) to develop buildings which are recyclable.

An architect's view

The adoption of environmentally responsible ideas and practices in building an extremely complex issue because of the extensive networks that develop for any one project [3]. These networks are at best temporary, in that they form for one particular project and dissipate when the building is completed. Since every building differs from the one that preceded it in some way (different site topography, different client, different consultants etc.) any new networks that form are likely to be different in their composition and goals to the one that went before. Therefore, the transfer of experience from one project to the next may not necessarily be possible or indeed applicable.

Before looking at the specific issue of site waste, it is necessary to look at the participants in the design and construction process, the nodes in the network. If we start with a very simple model, comprising a client, an architect and a general contractor and look at their potential contribution to the building process;

The client, whether an individual or a large corporate body, will affect the building programme by the amount of money and time available for a specific project. The aspirations of the client body and those of the individual, the client's representative, will also influence the process, thus clients have an important role to play in the adoption of environmentally responsible practices. One of the main contributions is the proposed design life of a building: from experience gained in an architect's practice this is one area where architects constantly strive to select products that are durable and have a long life in service but an area where the majority of clients require a building which will have a short life. For example, many buildings are designed with service lives of as little as 15 years, after which time they will be demolished and replaced simply because the client will profit financially from such a development practice. One (extreme) example of this was a client who asked for a building to be designed for a five year service life, after which time it was to be demolished and the site redeveloped, however, there was no possibility of designing for dis-assembly because of time and cost constraints imposed by the client.

As designers of the building and selectors of building products which make up its assembly, architects have a significant role to play in the adoption of sustainable practices. However, they are constrained by clients' aspirations and may often be limited in their action by constraints imposed by the client's pre-contract team and constraints arising from project constraints, discussed below.

As the actual builder, contractors are constrained by the designers instructions, the builder's environmentally responsible practices are limited to control and management of on site systems ensuring that wastes and emissions are kept at a minimum. Though discourse and feedback a contractor could aid or influence design changes on the current and future projects, however, such an exchange of information will be dependent on the architects and clients attitude towards contractor involvement in design issues. The contractor still has a role to play in the control of waste, indeed it is suggested that good site management can significantly reduce waste and control and reduce associated costs.

A construction manager's view

Presently a small percentage of the material is recycled: in 1994 it was claimed that 80% of construction waste ends up on landfill sites [4]. Even though this has been reduced by 43%, through the impact of landfill tax, it is suggested that much of the waste is diverted to unregulated activities such as golf course landscaping and land spreading on farms [5], however the burden of construction waste still rests with landfill sites. Although tax on waste bound for landfill sites has increased, it has not altered the fact that building are increasingly being built out of less disposable and recyclable materials at an increasing rate. The size of buildings and the speed of construction is increasing posing a massive problem for waste management, the amount of waste generated is obviously linked to the size of the structure, furthermore the new buildings have shorter life spans than their predecessor. In many cases "buildings are designed with obsolescence in mind", demolished after 25 years use [6]. The harm to the environment is at least three fold, demand on resources; emissions during building, demolition and recycling; and the impact of the un-recycleable disposable element of the structure.

Even though the industry both creates and fills voids, the situation. is not in equilibrium; waste generated by society is greater than the voids created by mining [7]. To remove the impact on the environment the industry should reduce its demand on raw material, through recycling and reuse, The burden of the extra tax on waste of the building bound for demolition is placed with the developer of the new building project. Although the building will incorporate the costs of removing previous developments, it is argued that the design of the new structures does not place sufficient regard to demolition, dismantling or assessing the eventual disposal of the structure, especially when life spans of buildings are being reduced. The responsibility for waste and the impact on the environment concerns every stakeholder in the building process [S]. Solutions to reducing waste must be at the forefront of all; clients, developers, designers, contractors, manufacturers and suppliers when designing their process or product. In research carried out on material control and waste on building sites [8], it was found that;

- Considerable waste of resources occurs when the project information is inadequate when work has commenced.
- Materials handled by plant not designed to handle the product leads to damage and waste.
- Inadequate or incorrect packaging leads to damage when handling.
- Untrained operative using incorrect procedures leading to damage.
- Inadequate stacking or insufficient storage space was a principal reason for waste.
- Excessive cutting of materials due to designers not taking account of practical sizes
- Material quality of the product delivered varied from specification leading to rejection and waste.
- Lack of supervision and responsibility led to misuse and damage of materials.

The research identifies many faults of material control leading to waste which could easily be rectified with practical material management systems.

(The following case studies were carried out before recent changes to financial levies on waste skips).

Case study 1

The following case study is based on an architectural firm's attempts to introduce a number of environmentally responsible practices, over a four year period. It is important to note here that the firm made no claim to be 'green', it was (and still is) a firm orientated towards the commercial market, with an excellent reputation for service and delivery. However, the firm attempted to implement better practices on every project, an aim not always achieved. There are two related issues explored here, namely the selection of building products and the control of waste on building sites.

First, the architects aimed to detail each building in excess of the then current thermal regulations. This added additional initial cost to the building, but some relatively simple arithmetic indicated that this was soon recovered through reduced heating costs, thus saving energy (and money) in the long run. Whilst some clients, usually owner operators, were relatively happy with this approach, clients who were developing a site for commercial reasons and who were going to sell the building on completion were not interested in the long term cost savings and insisted on the building being designed to the minimum standards required under the current Building Regulations to keep initial costs down: clearly not all clients are orientated towards a sustainable future.

Second was a desire to cut down on the amount of waste generated on building sites during the course of construction. This came about through a desire to reduce costs, through reducing waste material on site, paid for and not used, and also the cost of disposing of it to appropriate tips. Thus waste material attracted two costs, both of which, hypothetically, could be reduced, but which in practice is much harder to control. The cynic here would argue that it is not in the contractors interest to reduce waste because the firm makes a profit on all material purchased and makes a profit on transporting waste material to the tip. Others may argue that many contractors are simply unable/or unwilling to do anything about waste generated on site, simply because of well established (bad) practices, whilst others may well argue that it is in the hands of the architects. Such control requires additional time, for monitoring and supervision, both on behalf of the architect's office and the contractor. From an architect's perspective it is difficult to charge the client for this time, time which is not always available given programming pressures for fast completion.

The architectural practice were fortunate in having a small number of repeat clients who were concerned with environmental issues and did want to make a contribution, which helped to balance the clients who did not. The practice, with the backing of the client, undertook a small pilot scheme where an attempt was made to reduce waste generated on site. The first task was to f-e-assess the design of the building. Since the building had been refined over a number of years, with a view to reducing costs and improving design quality, the assessment found that little could be done. The issue of prefabrication off site was investigated, but since the buildings were all different to some respect (largely to suit site constraints and local planning requirements) this option was ruled out. Therefore material control at design stage had been considered. Next was to look at what happened on the site. Since a small number of contractors constantly won the competitive tender for the building there was some consistency here and two of the contractors were monitored over five projects each. The monitoring was very simple (since there was no time available to do anything more sophisticated) and comprised a visual inspection of the site tidiness by the clerk of works on his daily visits and a check of the number of full skips sent to tips, from documentation submitted by the contractor: the clerk of works also attempted to make a note of the contents in each skip from a visual inspection. At each pre-contract meeting the architects asked the contractors to pay special attention to site tidiness and to try and limit the amount of waste generated, to which they were happy to agree.

Once building work started on site things were not so simple. Of the ten sites monitored, (five for each contractor) each site had a different site manager and each employed different sub-contractors to carry out certain elements of the work. What the study found was that site tidiness and the number of skips sent to the tip were linked, the tidier the site the less waste, but more importantly both issues were associated with the personal characteristics of the site manager (regardless of which company he was working for). Clearly, the pressure to get the building completed on time and to a specified quality overrode any concerns about waste or site tidiness - with each building site monitored, as the programme neared its completion and the pressure to complete the building mounted, the site became increasingly untidy and the skips filled all the quicker. From a visual inspection the majority of materials thrown into the skip were re-useable, such as short lengths of timber, chipped facing bricks etc., whilst a lot of waste was generated from the packaging used to protect building materials whilst in transit from the factory to the site. Despite requests from the clerk of works and also the architects at monthly site meetings to address this issue the number of skips going to tips did not reduce significantly.

In analyzing this small study, a couple of important issues are evident. First, the values of the contractor (and the sub-contractors) are different to those of the architect and client. Second, control of waste on site is the contractor's responsibility (not the architect's) and therefore, if for whatever reason, the site manager does not concern himself with such issues there will be no reduction in waste. In the studies reported above it was clear that contractors had little experience, or desire, to control or even measure waste on site.

Case study 2

The following observations were made over a two year period. The case studies examine practices and procedures associated with the handling of skip waste on four different sites The significance of waste to the site agent is cost, waste costs money. The studies show that cost orientated site agents can save money by controlling waste.

The first site agent observed held what could be considered an authoritarian approach to site control, if waste increased beyond what was considered his acceptable waste limits he came down hard on the subcontractors threatening to withhold moneys for excessive waste. Subcontractors were instructed to protect their materials, where their materials were damaged the site agent refused to be involved. Subcontractors became much more vigilant, possibly even aggressive towards others who may have damaged their goods. Site organization and logistical arrangements were adhoc and as such the possibility of damaging materials was high, (profiled metal cladding panels were damaged in bulk quantity by site plant on one site, although this material was sent to be recycled, wasted energy would be involved in the process). Very few skips (in comparison to the other studies) left this site, all operatives and staff on site were made fully aware of the cost of waste. Due to the authoritarian style of management, on all issues, a low moral on the site was observed. Subcontractors did not cooperate, the majority of personnel were very defensive, however protection and personal responsibility for materials was clearly apparent.

Two of the other site agents also attached a high priority to the control of what materials went into skips. Both of these site agents seemed to be more aware of what could be sold or reused. The site seemed possibly more organized, good housekeeping seemed to hold a higher priority, and as such slightly more material was removed by skips: these contractors were operating profitable sites.

The fourth site agent although well qualified and experienced was not running an organized controlled site. Little emphasis was placed on waste control. Multiple skips were removed daily, the site agent repeatedly talked about good housekeeping, although the site was rarely clean, even though one operative had a full time position cleaning the site. For the operative cleaning, it was easier for him to clean what could be reused, for example, it is easier to fill a wheelbarrow with off cuts of timber rather than picking up bricks encased in concrete and mortar. Many of the 'labour only' subcontractors seemed to have as much material as they wished, selecting only the best and disposing of the rest. Poor quality work by subcontractors was allowed to get to an advanced stage of construction before work was condemned and pulled down leading to high quantities of waste. The site agent was not operating a profitable site. It is inevitable that any site agent adopting wasteful processes are placing themselves and their companies in a risky position because of the cost implications.

These limited observations identified how individuals were dealing with waste costs within their sites. Clearly site agents who are in financial control undertake waste management seriously. However, if further advances are to be made to reduce site waste, architects need to be more aware of process which create waste during the construction phases and those which are less wasteful. For example, concurrent engineering operated by other industries and now emerging in the construction industry [9] should engage in environmental assessments, coordinating efforts of both designers and contractors.

Conclusion - A way forward

The case studies, along with the authors' individual views help to illustrate the difference in culture between the design and construction phases in a buildings life. Although the case studies were not linked, there was a clear emphasis on cost, with environmentally responsible behavior closely linked to cost benefit. It was also evident that designers were looking to the site for improvements in waste control (outside of their control) and site agents were looking toward the designers for more to be done at the design stage (outside their control). The concept of individual responsibility within the temporary procurement team is an area for further investigation and research. Furthermore, it appeared that one of the main barriers to reducing waste on site was one of existing values and a lack of effective communication between parties.

Control of construction waste should be seen as a continuing process at all stages in the life of a building, but the wide variety of participants, all with differing values, goals and responsibilities, such control is always going to be difficult. It is the social and structural issues that need to be addressed rather than issues of a technical nature, combined with communication between designer and builder - in short a re-assessment of building procurement for an environmentally responsible age.

The Adjudication of Construction Disputes - New Dawn or False Hope?

P Newman, ***Construction Unit, Edwards** Geldard **Solicitors,** Cardiff, **UK***

Abstract: The UK Construction industry appears at times conflict driven. Claims based on time and money abound. Contractors do not look for 'win-win' solutions and use their lawyers to reach the position they desire through litigation or arbitration. Arbitration, at least in England, has come to resemble litigation with full use of lawyers, the legal rules of discovery and evidence and lengthy and expensive oral hearings. Sir Michael Latham was commissioned to review the practices of the UK construction industry and made a number of recommendations - greater partnering, a departure from the 'lowest tender wins' mentality, less adversarialism in dispute resolution. For Sir Michael, dispute resolution should principally be via adjudication (a term he never defined) and should be used regularly through the course of a project to deal with problems as and when they arose to prevent them becoming festering sores. The UK government enthusiastically embraced adjudication and rushed through hasty and, to some minds, ill thought out legislation. This paper considers the background to statutory adjudication, identifies what adjudication is and explores some of the merits and defects inherent in such a system. Adjudicative decisions must be interlocutory (although the parties may treat them as fmal and binding) not to offend against English arbitral law. Enforcement of adjudicator decisions may be difficult because of the wording of English standard form construction contracts and the provisions of the Arbitration Act 1996. How successful will be adjudication be? With little empirical data, the jury will remain out.

Key words: adjudication, arbitration, Arbitration Act 1996, Conflict, decision, enforcement, final and binding, Housing Grants, Construction Regeneration Act 1996, litigation, natural justice, Sir Michael Latham

1 **Why litigation and arbitration are failing**

A former Chief Justice of the United States of America, the late Warren Burger, once said:

> "The obligation of our profession is.. . to serve as healers of human conflict. To fulfil our traditional obligation means that we should provide mechanisms that can produce an acceptable result in the shortest possible time, with the least possible expense and with the minimum of stress on the participants. That is what justice is all about. "[1]

Leaving to one side the possibly conflicting emotions of those involved in the dispute resolution business, where certain lawyers need to question the value of a "litigation client who is not litigating" and thereby doing his 'duty' in creating billable hours, no sensible person could dissent from Warren Burger's comments. Dispute resolution is a service industry and must recognise client needs. Clients who believe they can abdicate their responsibility for decision making by passing a 'problem' to their lawyers have a rude shock when witness statements need to be produced and a court hearing beckons. Only then do they 'reality test' with the result the litigation implodes and the cost in terms of management time and money either disregarded or explained away. The need for client centred dispute resolution has been taken up by many leading members of the judiciary and was a cornerstone of Lord Woolf's interim and final reviews of civil litigation[2], Access ***to Justice.*** Another very senior judge, the former Lord Chief Justice, the late Lord Taylor, rightly said in identifying the obligation of the legal profession to be responsible in plying its trade:

> "A trial is not a game. The role of a judge should not be restricted to that of an umpire sitting well above the play, intervening only to restrain intemperate language and racket throwing. "[3]

Lord Taylor's remark echoed earlier words of Warren Burger who on one occasion said:

> "Trials by the adversarial contest must in time go the way of ancient trial by battle and blood" [4].

1.1 **Criticism of Litigation**

Increasingly, litigation, the legal process and the ways of lawyers and expert witnesses have attracted a very poor press. Particularly in the United States lawyers are the butt of savage jokes which emphasise their reputed avarice and self interest[5]. Even in the United Kingdom, when the City law firm, Herbert Smith, surveyed the top ***400*** companies in ***The Times Top** 1000* for their views on litigation the lawyers found widespread criticism of the length, complexity and cost of civil justice:

> "A substantial majority (70%) suggested the whole system takes too long, whilst almost ***40*** % suggested that the costs of litigation are far too high. "[6]

Companies apparently support a shift away from oral advocacy in civil trials and a greater emphasis on written submissions. They want judges, not the parties to the dispute, to control the pace of proceedings and to determine how long cases should take. More than ***60%*** of the firms questioned favoured a paper trial instead of one based on oral argument and evidence; and a substantial majority wanted control of the timetable of cases given to a ***procedural*** judge. On the face of it, this appeared to equate with a more inquisitorial approach rather than the painstaking, lengthy and costly Anglo-American example of testing evidence through an adversarial model with lawyers caught in the role of medieval knights in a joust.

Over the years various "captains of industry" have criticised the legal process. For instance, Ian Dixon, Chairman of Wilmott Dixon and the then Chairman of the Construction Industry Council, was quoted on one occasion as saying:

> "You can't win if you go to court. The high legal costs are part of it. Litigation is long and repetitive. The legal system is abysmal and inefficient. "[7]

Such stated dissatisfaction with litigation does not explain the continued willingness of UK parties to embrace adversarial methods of dispute resolution.

1.2 **Criticism of Arbitration**

Arbitration, traditionally promoted by its proponents as a no *nonsense* method of dispute resolution, relying more on technical assessment than on the application of judicial nuances, has for a number of years been regarded as legalistic in the United Kingdom unlike in the United States where it is categorised as an ADR method of dispute resolution. In ***Northern Regional Health Authority -v- Derek Crouch Construction Company Limited Sir John*** Donaldson MR stated:

> "Arbitration is usually no more and no less than litigation in the private sector. "[8]

Similarly overseas, the conclusion reached in an Australian research report into claims and disputes in the construction industry, ***Strategies for the Reduction of Claims and Disputes in the Construction Industry - a Research Report*** (various authors) was that:

> "... arbitration has broken down as a cheap and efficient means of resolving construction disputes, albeit that the cause may be the strenuously adversarial manner in which the disputants themselves pursue the arbitral process. "[9]

1.3 **Arbitration Act 1996**

Whether or not the Arbitration Act 1996 will improve the position and rehabilitate arbitration as a cost effective means of resolving commercial disputes in England time will tell.

The Arbitration Act 1996, the purpose of which is to breathe fresh life into arbitration, has had a long period of gestation. The Departmental Advisory Committee (DAC), latterly with governmental involvement, produced two draft Bills, the second of which went out to public consultation in July 1995. The aim was to restate English arbitration law in clear and *user-friendly* language. Some commentators supported the incorporation into English law of the UNCITRAL Model Law as had occurred in Scotland a few years ago. Decisions of the English courts, exercising their supervisory jurisdiction, had caused disquiet amongst foreign parties who chose London for their arbitration. The promoters of new English legislation decided that although the UNCITRAL Model Law had many useful lessons, English law and practice were too well developed by case law precedents to justify the wholesale adoption of the Model Law. The exercise became one of consolidating the Arbitration Acts 1950-1979, modernising their language and inserting apposite features from the Model Law.

Some of the key provisions in the English legislation are found in sections 33, 34 and 48. Under section 33(l)(b):

> "[the tribunal shall] adopt procedures suitable to the circumstances of the particular case, avoiding unnecessary delay or expense, so as to provide a fair means for the resolution of the matters falling to be determined".

Under section 34 the onus is on the tribunal to organise the arbitral reference and a checklist of appropriate considerations is included in sub-section (2). Important amongst these are (c) which attempts to address the English obsession with general discovery in litigation and arbitration and emphasise the point that discoverable documents should be limited to those which are pertinent to the issues in dispute. Further, and a major departure from English practice is the power found in (g) permitting the tribunal to decide "whether and to what extent the tribunal should itself take the initiative in ascertaining the facts and the law". English case law has long debated the power of arbitrators to adopt an inquisitorial approach and until the 1996 Act had given an equivocal response. Finally, the 1996 Act empowers the arbitrator to act as *amiable compositeur*. To what extent English arbitrators will be liberated from convention by the parties and invited to use the section 46(l)(b) powers remains to be seen.

2 The desire for change

The realisation that all was not well with the construction industry led to the Government/industry inspired appointment of Sir Michael **Latham** to review procurement and contractual arrangements in the construction industry. In his final report, *Constructing the Team*[10] he identified adversarial attitudes as a major cause of malaise in the English construction industry. One of the by-products was more expensive construction costs in the United Kingdom (30% higher than in the United States) which he wished to see reduced by the year 2000 (a view greeted with incredulity by the industry)[11]. For Sir Michael there were two responses to the industry's problems: (1) partnering at the front end of projects and (2) adjudication throughout the project to nip problems in the bud and resolve issues when they arose, avoiding unnecessary involvement of lawyers and claims consultants.

3 Adjudication - a new beginning?

Adjudication is not a new concept for English lawyers. It has been an intrinsic, even if peripheral, part of construction sub-contracts since the mid-1970s to review main contractor set offs although it is frequently deleted by main contractors and, because of the wording of sub-contracts forms, has been held not to bite on main contractor claims in abatement.

The definition of adjudication is somewhat vague and the distinction between it and arbitration fuzzy. This is because adjudication (leading to an imposed decision and adversarial, although of a muted variety when compared to arbitration and more particularly litigation) closely resembles arbitration in many respects. It fundamentally differs from arbitration in that the adjudicator's decision is interlocutory and not final. In effect, the adjudicator's decision is binding on the parties if they choose to accept it, or until such time as one of the parties commences legal proceedings or arbitration to determine finally the dispute or the parties, of their own volition, come to their own agreement. Although a contractual mechanism for the resolution of disputes, adjudication is quasi-judicial and subject to intervention by the courts. In England, intervention correlates with the principles of natural justice (ie. giving each party the right to understand the case being made against it, put its own case in its own words and understand the thought processes of the person (a neutral outside the influence of either party) making a decision). The courts are reluctant to lay down hard and fast rules as to what constitutes natural justice. In *Wiseman -v- Borneman*[12], Lord Reid stated:

> "Natural justice requires that the procedure before any tribunal which is acting judicially shall be fair in all the circumstances, and I would be sorry to see this fundamental principle degenerate into hard-and-fast rules".

3.1 Categorising the parties: dispute mechanism

The tension between an adjudicative and an arbitral procedure is sometimes crucial. The English courts will look at the underlying fundamentals of the parties!' arrangements rather than simply be beguiled by their nomenclature; [13]

> "The way in which the reference is described in the agreement to refer is not conclusive as to the character of the proceedings. Thus, even an explicit agreement that a matter be dealt with by arbitration does not mean that the parties intended the proceedings to be the type of arbitration which is the subject of the Arbitration Acts or the common law of arbitration. For example, the use of this word is consistent with any intention to invoke a process which involves a decision by any impartial body, but not one which is binding in law".

The interpretation of particular clauses has been considered in the common law jurisdictions. In ***Sports** Maska **Inc** -v- Zittrer*[14] the Supreme Court of Canada considered that the language used was not definitive and what may be described by the parties as an expert determination may, on objective analysis, be an arbitration. The question was also considered in England[15] where the Official Referee decided that what purported to be an adjudication clause in a management contract derivative was in fact an arbitration clause, given that the result was final and binding.

3.2 Adjudication and arbitration - the interface

A further potential problem adjudication has in England is enforcement of the adjudicator's decision where there is also an arbitration clause in the contract. ***A Cameron Limited** -v- **John** Mowlem &* Co *plc*[16] established that an adjudicator's decision was not equivalent to an arbitrator's award and was not registerable as an arbitral award under the Arbitration Act 1950 (now the Arbitration Act 1996). Typically, at the end of an adjudication, if one party refuses to comply with an adjudicator's decision, the other party will commence court proceedings to enforce the decision. The traditional route has been to seek either summary judgment (which involves a short hearing in which evidence is adduced by way of affidavit, without any witnesses being heard), or an injunction requiring the recalcitrant party to comply with the adjudicator's decision. For example, ***in Drake** & Scull Engineering **Limited** -v- **McLaughlin** & **Harvey** plc*[17] the Official Referee granted an injunction upholding the adjudicator's decision that monies be paid to a trustee stakeholder pending the outcome of an arbitration.

However, if the parties' contract contains an arbitration clause, alongside any adjudication clause, section 9 of the Arbitration Act 1996 would be triggered. This calls for a mandatory stay of any court proceedings brought if an arbitration clause exists in the parties' contract. Thus, existence of the arbitration clause would deprive the court of jurisdiction to decide whether the adjudicator's decision should be enforced (ie. either by summary judgment or by an injunction); the matter would then have to be arbitrated. The English Commercial Court has held itself unable to wriggle out of the mandatory stay[18]. This potential problem can be addressed by providing that the arbitration provisions in the agreement do not apply to enforcement of an interlocutory decision of the adjudicator. The Arbitration Act 1996 may be able to assist with enforcement of an adjudicator's decision. This is because (unless the parties otherwise agree) section 39 permits provisional awards similar to summary judgment or interim payments and section 48(5) allows an arbitrator to grant injunctions. Thus, a claimant having obtained an adjudicator's decision in his favour could immediately commence an arbitration and seek redress from the arbitrator at an interlocutory stage.

3.3 Statutory adjudication in the UK

Following Sir Michael's report[19] the UK government enthusiastically embraced adjudication[20] and legislation was rushed through Parliament to regulate one distinctive sector of the UK economy deemed unable to put its own house in order. Although at the date of preparation of this paper a commencement date for the legislation is still awaited, the UK government has sought to institutionalise adjudication, making it applicable to a wide range of construction contracts for work within England, Scotland and Wales. Subject to the exclusion of certain process plant contracts and domestic building contracts[21] the Act applies to the full range of construction contracts[22]. The HGCRA gives any party to a construction contract the right (but without imposing the obligation) to refer a 'dispute' (which is defined as any difference) to adjudication[23]. This permits the adjudicator to exercise a wide brief extending beyond time and money claims to include a consideration of questions of law, such as: is there a contract? is there a claim in quantum meruit? has there been a repudiatory breach or a wrongful termination of the contract? The term adjudication is not defined in the HGCRA although the HGCRA identifies one of the key features of adjudication by stating "the contract shall provide that the decision of the adjudicator is binding until the dispute is finally determined by legal proceedings, by arbitration (if the contract provides for arbitration or if the parties otherwise agree to arbitration) or by agreement" [24].

Prior to the enactment of the HGCRA in July 1996, the Department of the Environment, which oversees construction in the United Kingdom, stated that statutory adjudication would not resemble arbitration as currently practised there since unlike UK arbitration, adjudication would be "quick and inexpensive" [25]. In order to make adjudication work, the Department of the Environment is putting in place a 'Scheme for Construction Contracts' which will set the benchmark if the parties' contract is deficient in any regard. The first attempt at a Scheme for Construction Contracts[26] was almost universally condemned as a lawyers' charter. This led to a further consultation paper[27]. A draft Scheme for Construction Contracts Regulations was published on the 14th of August 1997 but has been widely criticised.

3.4 Adjudication - success or failure?

Adjudication which trundled on for many years with little or no profile was catapulted into prominence by Sir Michael Latham, leading to the preparation of various sets of adjudication rules[28]. Adjudication will not deal of course with the waste of managerial resources in the construction industry without profound attitudinal changes. It may address genuine claims but will phoney and bloated claims still be taken to the courts and arbitration? How will adjudicators react to contractors who may have worked their claims up over many months and then expect client and adjudicator to respond in a matter of days - is this justice or cynical manipulation of the process? So long as the 'cheapest tender secures the job' mentality persists and contractors artificially suppress their bids to secure work, conflict will inevitably arise when contractors attempt to clawback their position through claims. Adjudication can provide a mechanism for common sense but only to the extent that contractors and clients let it work. Adjudication will not work if one of the parties does not believe in 'truth will out' or reaches for his lawyers in order to thwart the process. Adjudication does have the potential to provide an ideal framework for the sensible resolution of many construction industry disputes and will be facilitated if the English courts demonstrate reluctance to overturn adjudicator decisions. But in the absence currently of empirical data the jury must remain out as regards its efficacy.

Procurement Methods And Contractual Provisions For Sustainability In Construction

G. Ofori and P. Chan
School of Building & Real Estate, The National University of Singapore, Singapore

Abstract
The construction process has major environmental impacts and its product relates to, interacts with, and adversely affects, the environment for several years. Various approaches have been proposed to help the industry to contribute to the general effort towards achieving sustainable development. These usually concentrate on the contractor's role, and the construction stage.

This paper considers the possibility of using the procurement approach, and contract provisions to achieve sustainability in construction in Singapore. It discusses the procurement arrangements which are utilised on construction projects in Singapore, as well as the relevant provisions of the two main standard forms of construction contract in use in Singapore. The paper considers areas where the procurement methods and contract forms could be modified to make them able to facilitate the adoption of sustainable construction operations, materials and equipment. It concludes that, as the awareness of potential end-purchasers and users of constructed items in Singapore of issues relating to sustainability increases, developers will have to adopt sustainable construction policies.
Keywords: Sustainability, client's role, procurement methods, contractual provisions, Singapore

1 Introduction

1.1 Construction, the Environment and Sustainability

The effect of construction activities on the environment is now well recognised. These include [1],[2]: (i) competition for land with other activities such as agriculture; (ii) adverse effect on the plots of land which are developed, and their environs, such as changing their ecological characteristics; (iii) consumption of substantial volumes of physical resources, both renewable and non-renewable; (iv) production of substantial volumes of wastes; (v) consumption of large amounts of energy during the processing of materials, the construction process and in the use of constructed items; (vi) contribution to air pollution from the dust and substances, including some toxic ones, which are released during the production and transportation of materials, and in some construction operations; and (vii) disruption of the lives of the people living in the vicinity of the project through traffic diversions, noise pollution and others.

Following the realisation of the relationship between construction and the environment, the need for construction to strive for sustainability in its activities is also understood [3],[2],[4]. Moreover, the nature of sustainable construction and the ways and means to achieve it are also quite established (see, for example, [5,],[6]).

1.2 Pre-eminence of the Construction Client

Construction clients are the prime movers of the work put to the industry. They appoint and pay all the other participants in the projects. Clients have different backgrounds, and dissimilar levels of knowledge of construction. They also have different motivations and interests. These features of the client are reflected in the objectives which they make clear to the project team through the project brief and the resulting production documentation prepared in response to the brief. As clients bear the overall financial risk, all the activities of the other parties involved in the project are, or should be, geared towards attaining the particular objectives of the client. For these reasons, in theory, at least, the client's key interests should drive the project.

Owing to the pre-eminent position of the client on the construction project, several authors (see below) have suggested that the issues relating to the attainment of sustainable construction can only be successfully addressed if clients show interest in, and commitment to, the concept of sustainability. This paper discusses the potential of using the procurement approach, and in particular, the contractual provisions, to achieve sustainable construction in Singapore.

2 Sustainable Construction in Singapore

Singapore wishes to be a "model Environment City" [7]. It has instituted measures to achieve this. These initiatives include [S]: (i) the publication of a ***Green** Plan*: (ii) the introduction of relevant statutes, regulations, codes, incentives, taxes and charges; (iii) the establishment of relevant administrative systems and public education programmes; and (iv) the publication of a document outlining the country's intentions to protect and enhance the built environment in its physical development. Ofori (1993) [8] discusses environmental issues in relation to construction in Singapore.

Studies have shown that whereas a few aspects of sustainable construction are clearly discernible in the operations of construction enterprises in Singapore, the concept of sustainability is not yet a major issue to the nation's construction clients and practitioners [8], [9], [10]. It is not addressed in a systematic or even deliberate manner. The Construction Industry Development Board (CIDB), which manages the continuous improvement of the construction industry in Singapore, and provides the lead on key directions for the industry, has not yet identified sustainable construction as a main consideration, although it realises the importance of environmental issues in construction and has drawn the industry's attention to them [11].

Several authors in Singapore have suggested that progress in the effort to achieve sustainable construction can only be achieved with clients' leadership. Ofori (1992, 1993) [1], [8] outlines the nature and scope of activities relating to the attainment of environmental objectives on construction projects, and highlights the pre-eminent position the client must take. In a recent study on the perceptions of construction firms in Singapore on the IS0 14000 environmental management standard, Tan (1997) [10] found that whereas the contractors professed their awareness of issues relating to sustainable construction, they were only taking action where they would otherwise infringe existing statutory regulations or charges such as avoiding the soiling of roads and the illegal dumping of waste. He concluded that the industry would only take action to protect the environment when the client demands it.

3 Potential of Procurement Approach

Sustainable construction or aspects of it may be imposed by legislation, the terms of the construction contract, or the policies of the developer, the designer, the project manager or the contractor. Any construction contract which provides for terms that contravene the legislative obligation would result in the terms being illegal, void and therefore unenforceable. On the other hand, the parties to a construction contract may agree to provide either in the conditions of contract or in the other contract documents, the obligation to achieve sustainable construction or aspects of it. Finally, the developer, the designer, the project manager or the builder can voluntarily adopt a policy to achieve sustainable construction.

3.1 Procurement Options

In the division of the legal responsibility in a construction contract between the developer and the contractor, three generic approaches to the procurement of construction projects may be considered. First, the developer may choose to bear all the responsibility for the design, workmanship, materials, methods of work and site operations. The client exercises maximum influence over the project by playing the role of designer and builder and employing workers to do the physical work. This arrangement requires the developer to enter into employment contracts with all the workers. This *Employment Contracts Arrangement* is not practised in Singapore.

In the Employment Contracts Arrangement, the developer has the full responsibility and therefore control of the design, workmanship, materials, methods of work and site operations. Accordingly, if the developer has a strong policy which promotes sustainable construction, this policy is likely to be translated into an actual achievement of sustainable construction. Even if the developer does not have such a policy, sustainable construction or aspects of it can still be achieved if the designer or the project management team engaged by the developer promotes and incorporates sustainable construction in their proposals to the developer.

In the second approach to the procurement of the construction project, the developer retains the design responsibility which includes prescribing for the necessary workmanship and materials, but engages the services of a contractor to do the builder's works. The contractor's responsibility would then be for methods of work and site operations. This arrangement is known as the *Traditional Approach.* This is popularly used in Singapore (as well as in the UK from where the procedure originated) by both the private and the public sectors of the construction industry.

In the Traditional contracts, the developer has control over the design, workmanship and materials. The developer who wants to promote sustainable construction can instruct its designers to incorporate features of sustainable construction in their designs and specifications for workmanship and materials. The developer, however, cannot interfere with the contractor's control over methods of work and site operations, otherwise the responsibility for any delay or defective works arising from the developer's instructions to change the method of work or site operations would revert to the developer. Whether the methods of work and site operations would follow the principles of sustainable construction is left to the contractor to decide.

In the third generic form of construction project procurement, the developer does not have any responsibility for design or construction because all the responsibility for the design, workmanship, materials, methods of work and site operations is allocated to the contractor in a *Design-and-Build Contract.* In recent years, the design-and-build contract has been gaining popularity with the developers in Singapore. It is favoured by the CIDB as a potential contributor to the effort to enhance construction productivity owing to the likelihood that it will result in buildable designs. It has been used on several public-sector projects as, led by the CIDB, the main public clients have declared their commitment to that procurement approach.

In a Design-and-Build arrangement, the developer relinquishes his responsibility and control over the design, workmanship, materials, methods of work and site operations of the project. The developer would instruct the contractor on its requirements and available budget. In response, the contractor produces the end product with everything under its control. Accordingly, the decision as to whether sustainable construction should be pursued is left to the contractor to make.

4 Potential of Contract Forms and Other Documents

The usual contract documents used in a construction project include the standard form of contract containing the articles of agreement and the conditions of contract. In Singapore, there are two standard forms in use. The Singapore Institute of Architects (SIA) Form of Building Contract (SIA Form) is used in the private sector. There are two forms, namely, the Lump Sum Contract form and the Measurement Contract form. They are used for Traditional contracts. The other standard form of contract is the Public Sector Standard Conditions of Contract (PSSCOC) which is used by public-sector clients. It is used for Traditional contracts and, with necessary amendments, for Design-and-Build contracts.

The other common contract documents for a construction project include the drawings, specifications and Bills of Quantities, if applicable. Finally, a construction contract may also include ***ad hoc*** documents such as letters setting out the agreements reached during tender interviews or other negotiation sessions.

There are generally two ways in which sustainable construction may be prescribed in a construction contract. Firstly, by using the quality prescription specifications where the known standards in respect of design, workmanship, materials, methods of work and site operations which allow sustainable construction to be achieved may be specified. Secondly, by using the performance prescription specifications where the known states of achievable sustainable construction are specified for compliance in respect of design, workmanship, materials, methods of work and site operations.

The discussion in the rest of this section is on how the contract documents may be used in Traditional contracts to procure sustainable construction since the Employment Contract Arrangement is not used in Singapore and Design-and-Build Contracts place all responsibility for the completion of the project on the contractor. The discussion is based on the assumption that the developer is motivated by a policy to pursue sustainable construction.

The SIA Form and the PSSCOC oblige the contractor to comply with all existing statutes and regulations, including any legislation which supports sustainable construction. Thus, by clause 7(1) of the SIA Form:

> The Contractor shall comply with ...any instrument, rule or order made under any written law applicable or any regulation or bye-law of any Government authority or any statutory undertaker which has any jurisdiction with regard to the Works or with whose systems the same are or will be connected.

The corresponding part of clause 7(1) of the PSSCOC has a similar provision. Examples of such statutory provisions for sustainable construction includes prohibition of the disposal of waste through burning in open fires.

In Singapore, two aspects of design which may be considered to be in support of sustainable construction and which have- found their way to the contract documents, namely, the drawings and the specifications, are buildable design and the use of pre-fabricated components. In both instances, the percentage of wastage in materials and labour should be reduced. Any other design in support of sustainable construction may be introduced into the contract documents in the same way.

Although in the Traditional contracts, the control of the methods of work, temporary works and the site operations rest with the contractor [See clause 2(1) of the SIA Form and clause 4.2 of the PSSCOC Form], it is possible for the architect to instruct the contractor to vary the temporary works or methods of working where this is so desired by the architect or the employer under clause 1(4)(b) of the SIA Form. However, this is not expressly provided under the PSSCOC although clause 2.1(1) provides that the authority of the Superintending Officer shall be that stated in or necessarily to be implied from the Contract.

Therefore, it is possible for the Employer using the SIA Form to oblige the contractor to use temporary works and work methods which produce sustainable construction but the contractor must be compensated according to clause 2(3). The clause provides that:

> If any accident, loss, liability, claim or damage subsequently occurs as a result solely of the use of the methods of working or temporary works ordered by a direction or instruction of the Architect under sub-clauses l(3) and (4) of these Conditions and sub-clause (2) hereof . . . the Employer will indemnify and if appropriate pay compensation to the Contractor in respect of the same, provided that the accident, loss, liability, claim or damage would not have occurred if the Contractor's preferred or previous methods of working or temporary works had been used, and provided further that the Contractor has complied with the Architect's direction or instruction with due skill and care.

Another area in which the developer may exercise control to promote sustainable construction is in respect of the plant and equipment used by the contractor to carry out his work. Currently, the standard forms require the contractor to enter into an agreement with the owners of any hired or hire-purchase plant and equipment to assign the benefits of the hire or hire-purchase contracts to the employer before the contractor may bring such plant and equipment for use on the site [See clause 16(4) of the SIA Form and clause 24.4 of the PSSCOC]. This requirement may be extended to oblige the contractor to ensure that all plant and equipment to be brought on to the site would accord with the principles of sustainable construction. This must necessarily be accompanied by a provision to compensate the contractor should this requirement result in a delay to the completion of the works or other losses.

5 Discussion

5.1 The Cost-Benefit Equation

The contractor is unlikely to derive significant direct, short-term commercial benefit from the use of sustainable construction methods of work and site operations on a particular project since the contractor has to work within the contract sum. Therefore, there is no incentive for him to pursue a policy of sustainable construction after being awarded a contract. Indeed, Tan (1997) [10] observed that the contractors he interviewed were adopting a "wait and see" attitude. No construction company in Singapore has yet followed Hawken's (1993) [12] advice on the commercial merits of adopting policies of sustainability.

Likewise, the developer may not be motivated to adopt a policy of sustainable construction because he may not derive any direct benefit. Thus, in the medium term, private clients are unlikely to require construction enterprises to adopt sustainable construction practices. However, in Singapore, the procurement policies of public-sector client organisations are likely to make the difference. After large and medium-sized contractors meet the requirement to be IS0 9000 certified by July 1999 before they can undertake public-sector projects, IS0 14000 may be the next milestone which the CIDB and public clients will encourage sizeable construction firms to achieve.

5.2 Other Driving Forces

A possible, more fundamental, driving force of sustainable construction in the private sector in Singapore is the preference and thus, demands, of the potential end-purchaser or user of the completed item. Such persons or organisations may "encourage" the adoption of a policy of sustainable construction by the developer as they express a choice for constructed items built in this way through their approaches to the purchasing of units. However, this would require end-purchasers and users to be knowledgeable about sustainability in general, and sustainable construction in particular. The process of "developing" such a person in Singapore is underway.

In Singapore; a public education campaign is mounted each year (during the *Clean and Green Week).* In the past three years, emphasis has been put on Green *Design* during this week of lectures, seminars, exhibitions and public shows. A few pressure groups also pursue the matter of sustainability throughout the year. A *Green Labelling* scheme has been introduced to inform consumers about products made in a sustainable manner. Moreover, the youth are being made aware of these issues through the educational curriculum. While enlightened purchasers or users (in relation to sustainable construction) will not emerge in significant numbers in Singapore in the medium-term, developers must prepare for the advent of such a person by adopting appropriate policies. In this regard, the procurement approach adopted, and the contractual provisions, offer scope.

Developers may seek to engage only construction firms with demonstrable sustainable construction policies, for example, as in their IS0 14000 certification, or incorporate in their contracts provisions which oblige construction companies to adopt sustainable construction approaches on their projects.

A final driving force is legislation. This will impose obligations on the developer and contractor to pursue sustainable construction policies. In such an event, construction contracts would incorporate provisions aimed at achieving sustainable construction.

6 Conclusion

The issue of sustainability in construction has not yet received significant attention in Singapore. However, owing to the actions of pressure groups and an on-going national public education campaign, the potential end-purchaser and user of constructed items is being made aware of the concept of sustainability. Developers may soon find it commercially necessary to adopt a policy of sustainability. The public client is likely to take the lead by adopting It should be possible for both public and private sector clients to achieve their aims in this connection through the inclusion of appropriate provisions in the forms of contract which they adopt on their projects.

Matching Contract Procurement Systems to Particular Construction Environments in Developing Countries

Winston H.E. Suite
Construction Engineering and Management Programme, Department of Civil Engineering, The University of the West Indies, St. Augustine, Trinidad, W.I.

Abstract

Developing countries have now been inundated with an array of emerging contract procurement systems. Against a background of physical, climatic, manpower and other resource limitations, these countries are faced with a fundamental question. Which contract procurement system is best suited to any given situation? Which method of measurement and of payment is then the best match with the selected procurement system? Clients increasingly wish to know which procurement system is most appropriate and upon what criteria or characteristics does this decision depend. The paper attempts to present a methodology based on a number of selected indices which define the specific construction environment, the client's objectives, the status of the client organisation and the nature of the project. The paper uses principally the experiences of Trinidad and Tobago over the last two decades as well as other contracts let in the English-speaking Caribbean.

Keywords: Contract Procurement, Measurement, Payment Monitoring, Scheduling, Payment, Quality and Satisfaction.

1 Introduction

The anglophone Caribbean island-states have had a long and deep dependence on the British legal system and its construction practice. They have therefore developed an intimate knowledge of and a confidence in the contract procurement systems emanating from the U.K. Up to the start of the second world war all its technology, the training of its construction professionals and subprofessionals (technicians), the construction text and reference books, affiliations with professional bodies, all were UK based. The influence of Canada and the United States of America had peripheral impact on the regional construction practice. The impact of the other European states was insignificant, if not non-existent. One may say that our colonial link with the U.K. shielded Trinidad and Tobago as well as the rest of the English-speaking Caribbean from any other external influence. After the second world war, a trickle of US and Canadian Engineering and Architectural graduates returned and presented a conduit to the North American influence.

The US military involvement in the region during and some time after the great war served to intensify this influence. The Canadian influence was to increase due to increased opportunities for students to study at Canadian universities. But the impact also increased due to the presence of the Canadian International Development Agency (CIDA) as an aid vehicle and later due to Canadian firms which began to appear. They were to come as joint venture arrangements or as independent consultants or contractors.

The U.S. involvement was to increase because of the geopolitical dynamics in the region and the axis of influence was to shift to the US as the dominant external influence. The U.S. investment in the petrochemical sector intensified the presence of US firms in the full range of relationships from joint venture, foreign direct investors, design and build contractors, design (engineers and architects), contractor builders and later project managers. US influence in the construction sector and particularly in the evolving contract procurement systems was to become the dominant influence displacing the earlier unchallenged position of the U.K. construction fraternity. This was elevated to even greater status as a result of the multilateral and bilateral lending mechanisms emanating out of the U.S. market. The leading influence can be identified as the IMF, the World Bank and the IADB.

2 Existing Contract Forms

Within the context of the British construction experience the Caribbean and indeed the Trinidad and Tobago construction sector was nurtured in the use of the traditional contract procurement systems. In Trinidad and Tobago the construction sector was very familiar with the different types or forms of contracts in all their variations e.g.

- (i) Admeasurement Contracts, both with Bills of Quantities and with Schedule of Rates.
- (ii) Lumpsum Contracts.
- (iii) Cost plus or reimbursement contracts.
- (iv) Direct labour or labour only contracts.
- (v) All-in contracts.

This classification tells how the works to be carried out shall be measured and hence payment made.

In this context the young construction professional but particularly the client would present the question to the consultant: "Which one is to be chosen in any particular situation?" and "What is the basis for the selection?" Here usually years of experience guides the consultant into a choice even if he/she does not commit to paper or oral defense, the detailed reasoning. But the form of arriving at a choice does not negate the fact that a national system can be constructed to guide the choice. Each system has advantages which would recommend its use and each system has disadvantages that we must be mindful of. Each system would therefore suggest that upon its selection a series of mechanisms or systems must be put in place to minimise the negative effects or obviate the weaknesses or difficulties. In fact the consultant should seek to rank these various systems in the context of the particular project and the project environment. It would follow that for a given situation one contract form would be more suitable or advantages (appropriate) but should we be constrained to choose another contract form the consultant must know what complementary systems must be involved.

3 The Conventional Building Procurement Systems

Up to the mid 1970's the local construction sector had settled into award of contracts of either the following types:

(i) The early master builder contract, the precursor or forerunner of the modern day design and build contract. This procurement system has survived, particularly used with small projects and where the design component is simple or minimal.

(ii) The traditional contract (delivery) system with Consultant/Designer and Builder/Contractor.
Here the design function is separated out from the construction function. In fact there may be two separate design contracts, one with the Architect and other with the Engineer.

(iii) The Package Deal and Turnkey Contract
In this the single contract procurement system ensures the delivery of the works and binds the two parties.

(iv) The Design and Build contract. This procurement system is similar to the turnkey contract in that a single contract binds the parties and circumscribe both the design and the construction aspects.

The favourable or appropriate condition for selection of one of these systems has been discussed by Franks (1984) in a guide to building project management.

The construction boom which Trinidad and Tobago experienced (1974-83) as a direct result of drastic increased oil (petroleum) prices was to witness a new advent of contract procurement systems. The author (Suite, 1993) dealt extensively with the emerging contract procurement system in showing what specific conditions led to the introduction of each new emerging procurement system.

4 New and Emerging Procurement Systems

4.1 Multiple or Separate Contracts

Large construction projects were in a number of cases divided into several discrete and separate contracts. Infrastructure projects easily lent themselves to this strategy. Road construction projects were segmented into smaller lengths so that several local small contractors could participate. This device permitted local contracts to meet bond and insurance and undertake a portion of the work which was well within their capacity. It proved useful in containing haemorrhaging of scarce foreign exchange since a large contract would in many cases rule out local contractors thereby necessitating the use of foreign contractors.

It must be admitted that this strategy of multiple contract award brought with it a greater opportunity for conflicts, disputes, delays and even litigation. The multiple contract system required greater monitoring, coordination and scheduling: It was to lead to greater use of project managers.

4.2 Project Management

The increased complexity and the need to execute projects on time and within budget have led to the emergence of two forms of the Project Management Procurement Systems, the Project Manager as Main Contractor and the Project Manager as Main Consultant. A great deal has been written on both these forms

4.3 Design, Finance and Construct Procurement (DFC)

The end of the construction boom in Trinidad and Tobago saw the next wave of contract procurement systems being introduced. This new service revolved around the situation in which these clients, often the State as central government or as statutory authority, did not have immediate access to the funding but nevertheless wanted the works to be carried out. This was the subject of an earlier paper (Suite, 1987). In this system the contractor provided the design, the finance and the construction, to be paid after the project was completed. This was the Design, Finance and Construct (DFC) system.

4.4 Equity Financing

Equity financing was to be introduced into Trinidad and Tobago as the next initiative of the private sector, with the financial institutions acting as the local partner. This spawned several systems, the best known is the Build, Own, Operate and Transfer (BOOT). Others in the series included the Build, Own, Operate (BOO) and the Build, Own, Lease, Transfer (BOLT). In this procurement system and its several derivatives, the contractor is both a developer and an investor. In some instances he may be prepared to operate the facility (BOOT) for some period before transferring ownership back to the intended client or owner. The contractor as investor provides the funding as well as the design and construction. In one case (BOOT) the contractor then operates the facility for a period to recover his investment and a return on the investment after which, title or ownership is transferred to the original client. In another instance (BOLT) the contractor leases the facility to the client who pays a rent or lease for use of the property for a period after which title is transferred to the client.

Initially, here in Trinidad and Tobago, it was the state through the central government or the statutory authorities, short of funds, that sought to enter into these arrangements. Today, private sector firms have began to enter into these arrangements. The present situation has produced two interesting examples. In one instance, the central government has leased a building from a private company which built the facility. This permitted the state to end a number of rental arrangements for several offices which are all now housed in a single building.

In another instance a private company that is involved in property development has recently constructed an office block to serve as the regional headquarters of a multinational company operating locally. The multinational has entered into a lease as part of a BOLT arrangement.

What has emerged is four different types of procurement systems available to the client.

- (i) Traditional Procurement System - (Client financing)
  - (a) Master Builder
  - (b) Traditional Contracts (Separation of functions)
  - (c) Package Deal/Design and Build/Turnkey
- (ii) Project Management Based Procurement System
  - (a) Multiple or Separate Contracts
  - (b) Project Manager as Main Consultant
  - (c) Project Manager as Main Contractor
- (iii) Deferred Payment or Debt Financing Contract Procurement
  - (a) Design, Finance and Construct
  - (b) Construct Financing (Consortium)
- (iv) Equity Financing/Joint Venturing (Contractor Financing)
  - (a) Joint Venturing (Partnering)
  - (b) Build Own Operate (BOO)
  - (c) Build Own Operate Transfer (BOOT)
  - (d) Build Own Lease Transfer (BOLT)

The question will forever be on the agenda. Which procurement system is best for a given system? The author in studying the Caribbean experience has attempted to deal with this issue in pointing to developing trends (Suite, 1994).

5 ‘The Emerging Picture

We are in a position to summarise before commencing by analysis.

The different measurement and hence payment system identified must be matched to the procurement systems.

Admeasurement		Traditional Payment	(a)
Lumpsum		Project Management	
Cost Plus (Reimbursement)	x	Deferred Payment	(b)
Direct Labour		Equity Financing	
All-in Contracts			

Several environmental factors determine how the analysis will begin and how it will proceed.

We may list some of these factors which will almost preselect, direct or restrict the selection.

Question # 1 <u>Financing</u>

Does the client/owner have the funding? If he does, then traditional procurement or project management immediately recommend themselves. If he does not, then he must have recourse to deferred or debt financing or equity financing.

Question #2 <u>Time</u>

Is completion time critical (of the essence), requiring close monitoring and dovetailing of schedules?

Question #3 <u>Technology</u>

Is the project complicated or requiring new technology or highly specialised knowledge, experience and skill, are there a few competent firms?

Affirmative answers to questions #2 and #3 would both favour either the Design and Build/Turnkey/Package Deal or the Project Management procurement systems. The former would permit fast tracking and single point responsibility and the latter would require continuous monitoring and synchronised scheduling.

Question #4 <u>Familiaritv</u>

Is the client/owner almost totally unfamiliar with the needs of the facility, and has no in-house experience or competence?

An affirmative answer would suggest a need for greater reliance on consultants. The traditional procurement system or the Project Management Systems would offer advantages.

No Finance Available to Client/Owner	Time of the Essence Client non-familiar New Technology Finance may not be able to raise	Equity Finance (BOOT) (BOLT)
	Time of the Essence Client Familiarity Standard Taking Finance can be raised in the future	Debt Financing D.F.C.
Client/Owner Finance Available	Time is of the Essence	Project Manager as Main Contractor Design and Build
	Client non-familiarity large complicated project New Technology	Project Manager as Main Consultant
	Technology well established	Traditional specialisation

Question #5 Straightforward

Is the design process straightforward or completed? Can all the work components be accurately anticipated and measured? Is the scope of the works well defined?

Nature of items clear; Sequence clear but quantities not precise	Admeasurement contract
Design incomplete, Sequence and scope of works not clear	cost plus Reimbursement

If the Principal items and scope of works are well established but a number of smaller items cannot be accurately evaluated then a lumpsum may best cover these.

Question #6 Capacity

Does the client/owner have capacity in terms of equipment and/or materials required for the project?

An affirmative answer would suggest a direct-labour contract.

A negative answer would suggest an all-in contract

One can ask several other questions to assist in the optimum matching of contract measurement and payment system with available procurement systems.

The first task with which the client and/or his consultant is faced is to select the procurement system.

Matrix #1 Questions

Procurement System	Finance	Time	Technician	Familiarity	Straight-Forward	Client Capacity
A. Traditional Systems						
. Master Builder	-		-	-	-	-
. Traditional/Separate Function	-	-	-	-	-	-
. Package Deal/Design and Build/Turnkey	-	-	-	-	-	-
B. Project Management						
. Multiple/Separate Contracts	-	-	-	-	-	-
. Project Manager, Main Consultant	-	-	-	-	-	-
. Project Manager, Main Contractor	-	-	-	-	-	-
C. Deferred Payment/Debt Financing	-	-	-	-	-	-
Design, Finance and Construct	-	-	-	-	-	-
Consortium Financing		-	-	-	-	-
D. Equity Financing						
Joint Venturing	-			-	-	-
Build, Own, Operate, Transfer			-	-	-	-
Build, Own, Operate		-	-	-	-	-

Having set a ranking system and selected the most appropriate procurement system, the next task is to decide how the work items or the entire works are to be evaluated and measured. This will determine how progress will be monitored and schedules of completion time tracked (and updated), how quality of work will be determined. Above all, upon what basis will monies be paid.

Another matrix of contract form vs questions, would facilitate the selection.

Matrix #2

Contract Form	Complete Design	Quantities easy to Identify	Time	Technology	Straight-Forward	Client's Capacity
Admeasurement						
Bills of Quantities	-	-	-	-	-	-
Unit Rates	-	-	-	-	-	-
Lumpsum	-	-	-	-	-	-
Cost Plus/Reimbursement						
Cost plus fixed fee	-	-	-	-	-	-
Cost plus percentage	-	-	-	-	-	-
Cost plus fee plus percentage	-	-	-	-	-	-
Direct Labour (Labour Only Contract)	-	-	-	-	-	-
All-in Contract	-	-	-	-	-	-

It would follow that a number of questions asked to assist in selecting the procurement system are again relevant in respect of how the work is to be measured. The two matrices are therefore limited. One may conclude that some procurement systems are more easily matched with some forms of measurement.

Matrix #3

Procurement System	Risk
A. Traditional System	MB carries all risks to deliver
Master Builder (MB)	Risk divided between Consultant(s) and Contractor(s)
Separate Financier	
Package Deal, etc.	Contractor carries all risk to deliver
B. Project Manager	
Multiple Contract	Risk shared by each contractor and consultant
Project Manager - Main Consultant	Risk shared by Project Manager
Project Manager - Main Contractor	Risk carried by Project Manager
C. Deferred Payment/Debt Financing	
Design, Finance, Construct	Contractor carries all risks
Construction Financing	Risks shared between Financier and Contractor
D. Equity Financing	
Joint Venture	Joint Venture plus share risk
BOOT	Developer carries risk
BOLT	Developer carries risk
BOO	Developer operator carries risk
E. Admeasurement Contracts	Contractor carries risk
F. Lumpsum	Contractor carries risk
G. Cost Plus Reimbursement	Client/owner carries risk
Direct Labour	Client/owner carries risk
All-in Contract	Contractor carries risk

Summary

Selecting a contract procurement system and a measurement/payment system is a question often posed by both student/young construction professional and client. Some projects within a given construction climate seems naturally to suggest one combination. Some contractors and consultants have preferences. But the final choice must be based on a number of internal or inherent factors specific to the project type. The choice must also be made based on the prevailing external or environmental factors, including availability of finding, technology, contractor and consultant experience and skill, state of national economy, urgency of the project, to list but a few. The selection must be justified, based on objective answers to a series of relevant questions. Nevertheless, the system being advocated would generate a priority ranking of procurement types, each one offering advantages and disadvantages. In some cases the client may see an upper hand in transferring the risk to the contractor, should one procurement system be selected. The contractor may prefer yet another because his risk would be reduced. Should the final section go either way both parties must know what are the risks and how they can be reduced. In essence each procurement system has apportioned the risk differently. This is the central issue to determine.

One may ask what is the nature of the risk? Obviously there are several different types of risk. There is the risk inherent in construction difficulties (on site). There are risks associated with the market such as change in prices or even the need for the facility and hence the viability of the project once completed i.e. that the assumptions, upon which the feasibility was predicted were valid (then) and realised (later).

Now risk relates to the uncertainty. The issue is therefore who carries the responsibility for factoring in the uncertainty? Contract procurement systems are therefore different devices for realising the project (works) with differing allocation of risks.

Building Procurement and Organisational Learning - Missed Opportunities

Derek H.T. Walker[1]
Department of Building and Construction Economics, Royal Melbourne. Institute of Technology (RMIT) University, Melbourne, Australia *[walker@ rmit. edu.au]*
Beverley May Lloyd-Walker
Department of Management, Victoria University of Technology, Melbourne, Australia.*[BevLloyd-Walker@vut.edu.au]*

Abstract

A series of recent Australian studies into construction time performance revealed that neither the building construction companies nor the client undertook any meaningful organisational learning activities to ascertain what could be learned from the experience of managing building and civil engineering construction projects. Post project evaluation studies were not required for the building and civil engineering projects but this was not the case for the process engineering projects. A post project evaluation was expected by clients and provided as part of services procured for process engineering projects.

Organisational learning codifies experience gained by individuals and teams in a form that adds value to an organisation. Learning is an asset, comprising intellectual property, which can be reused to add competitive advantage. It is also an effective means by which innovation can be introduced to organisations. Innovation is often generated from team members' personal experiences brought with them from one temporary organisation to another.

It is argued that the building industry should not only initiate post project evaluation but also a process of continuing organisational learning during the entire life cycle of the project.

capitalising upon their organisational knowledge assets. Also, clients should expect advice that allows them to achieve more sustainable projects with lower life-cycle costs, improved quality of product delivered and quicker construction times. Clients should, therefore, expect improvements in the project delivery process.

Research into changes in construction time performance of Australian construction projects between 1979 to 1992 revealed that construction time performance productivity increased between 19% and 38%. This productivity gain can be explained by technical improvements in the process of managing construction and team relationships improvement those involved in the construction process (Walker 1995).

The construction industry has no formalised process, insisted upon by the client, to ensure that reflective learning takes place in the form of rigorous project reviews. In a series of studies reported upon by Walker and Sidwell(1996) only 6 projects out of 45 had undertaken formal post project evaluation and these 6 projects were process engineering projects. Thirty-three projects were building construction and the remaining six were civil engineering projects clearly indicating that the construction industry pays little attention to finding a way to codify or record lessons learned.

A contrast was found between process engineering projects and building and civil engineering projects, which may be explained by the nature of the commissioning exercise for process engineering projects. These projects entail the commissioning of plant and equipment which process hazardous materials. Clients and contractors feel a greater incentive to ensure that lessons learned result in improvements to these projects, which are constructed for maximum safety levels when operational. Clients, such as the major oil companies are sophisticated procurers of construction services. British Petroleum (BP) and Mobile regularly use partnering and/or strategic alliances with a critical emphasis on project partners meeting strict quality provisions for audits of the construction process in order to 'capture' lessons learned (Prokesch 1997). This does not appear to be the case in the construction industry, which has a client profile where repeat projects are less likely to be activated within several years. It is, however, interesting to note that the mean construction time performance of the process engineering projects performed equally with the other projects (Walker 1997a).

The issue of post project evaluations not taking place poses interesting questions. For example, is the current procurement system adopted by the construction industry:

- Leading to a lack of organisational learning ?
- Depriving clients of value from experience gained ?
- Depriving the construction development team (suppliers, contractors and consultants) of the opportunity to enhance their competitiveness?
- Inhibiting construction development teams applying innovative processes and products?
- Inhibiting sustainable development?

The Value of Learning

"Complacency bred of past success leads to unexamined assumptions, blind spots and taboos that not only block the creation of new mandates among managers but also make it very difficult to sense, communicate and use intelligence about future trends." Marchand's (1997) comment underscores the need for strategic thinking about how to improve the provision of built projects. It is one thing to undertake an informal review of lessons learned but quite another to build a system where learning is readily available and easily communicated to those faced with problems and issues where past learning would be of help. A structured and codified way of capturing learning is needed as no learning can take place in an organisation unless it possesses a proper memory system (Tsang 1997, p78).

This is a leadership issue. It is a leader's task to design a learning process whereby people throughout the organisation can deal with and master the critical issues they face (Senge 1992, p345). Senge also stresses that shared vision is the product of a process that develops from extensive and often intensive communication between team members about each person's perception of what has, and is, occurring. This is an organisational learning process. Through communication of different and parallel perceptions of 'history', teams can gain a truly shared vision that builds their own understanding of 'truth' (Senge 1992, p231). Thus shared objectives are grown and joint commitment strongly established.

Team members who take the time to share their views of events have a more valuable collective view of 'the facts' (Senge 1992, p235). This added value allows them to be more flexible and rapid in amending their response to changing circumstances. This may help explain why a recent study found that there was a 33% improved mean construction time performance for construction management teams who exhibited a very high level of flexibility in adapting plans to meet new conditions (Walker 1996). Fisher highlighted the importance and value of organisational learning in the construction industry with an interesting insight into a Construction Industry Institute (CII) research project on a process for modelling lessons learned. She makes the point that *"Owners and contractors must depend on job end reports and/or rapid communication to transfer lessons learned from project to project. In today's fast track project environment, this is virtually impossible without a formal, systematic process that is to some extent automated."* (Fisher 1997, p36).

In a paper on organisational learning from natural disaster management, Carley and Harrald (1997) report on the activities of the Red Cross and other US agencies dealing with disaster relief. They state that the Red Cross has difficulty in measuring effectiveness for post project evaluation because they use shallow performance measures such as 'X' meals served, and 'Y' persons sheltered. The learning achieved only identified was what was done and not what was needed to be done. Learning must be based upon deep reflection and critical analysis not shallow metrics. Context needs to be explored and reviewed so that past experience can be used to model new situations. This allows the additional benefit of providing a framework for simulation testing.

Constantine (1993) offers an interesting technique for use in recording organisational learning, which he refers to as 'Design by Walking Around'. In this approach a continuous record is kept of what the group does. This is similar to what is understood as a 'global method statement' in the construction industry (Walker 1997b). Records of the process, strategy, and other key management approaches together with the success or otherwise of outcomes are maintained. The recording medium is unimportant, but essentially three sources of 'bins' are created for storing ideas pertaining to problematic issues. In one 'bin' success stories are recorded noting reasons for success. In another 'bin' failures are similarly recorded; again reasons leading to this outcome are recorded. The third 'bin' contains deferred decisions, in-progress, and undecided responses to issues and problems. This 'bin' can contain gems of knowledge to be used at a later time because they were not implemented due to current circumstances and environments not being conducive to success. This approach offers a model for undertaking continuing review and learning. In this way, organisational learning can be shared and maintained for easy access.

It is clear from the general management as well as construction management literature that the value of learning from past experience plays a crucial role in building process improvement. It is equally clear that this activity needs to be encouraged and structured into the management process. If companies are not initiating this to the extent required for significant and sustained productivity improvement, then clients should consider making the process a contractually required part of services provided by construction teams.

Innovation and Organisational Learning

Nam and Tatum (1997), in a study of 10 innovative projects in the USA, stress the importance of leadership by the client (owners) of the facility in fostering innovation. Seven out of the ten projects case studies showed owner leadership and involvement as being pivotal in adopting innovative practices. They believe that technical competence is largely responsible for this propensity for innovation. Further, their study indicates that in eight out of the ten cases *"managers with the authority for approval of key ideas in the construction innovation had a high level of technical competence"* (Nam and Tatum 1997, p265). They also found that technologically competent managers devoted time to continued learning about technical matters. This can be achieved through undertaking post project evaluation. Nam and Tatum (1997, p267) also stress the need for slack resources to be made available in the form of time or funds. Again this can be effectively used to fund a post project evaluation process.

Another popularised management theory of the early 1990's was re-engineering. This concept espoused by Hammer and Champy (1994), explores the tension between what is referred to as 'inductive' and 'deductive' thinking applied to business process improvement. *Inductive* thinking is described as the ability to first recognise a powerful solution and then seek the problems it might solve (Hammer and Champy 1994, p84). Thinking *deductively* about technology not only causes people to ignore what is really important, it also gets them excited about technologies and applications that are, in fact, trivial and unimportant (Hammer and Champy 1994, p86). Their propositions were widely regarded as a radical approach because they essentially advocated a revolutionary zeal in starting again from scratch in developing process improvement. Hilmer and Donaldson (1996), however, caution against mindlessly adopting the latest American Business ‘fad’ or ‘quick fix’. They rightly make the point that shallow thinking does not lead to productive organisational learning. While it is perfectly valid to question assumptions they do need to be abandoned. In fact, being innovative requires us to deeply consider how circumstances may have changed from those underpinning existing processes, and making appropriate flexible changes to accommodate new realities. This again requires reviewing and learning from the past, suggesting that clients who encourage this kind of review can contribute to industry improvement through organisational learning.

Sustainable Construction Principles and Organisational Learning

In describing an Environmental Management System (EMS), Hill and Bowen (1997, p236) identify as a key requirement that *“an audit report provides an essential information feedback loop to management who can take corrective action to address weaknesses of the EMS”*. Several aspects of management processes are included in a four ‘pillar’ EMS system advocated by Hill *et al* (1994). Organisational learning can address sustainable construction principles through designing to meet the clients needs and objectives to minimise complexity which could demand unnecessary resources. In this way it can be seen to be in accord with constructability principles (McGeorge and Sidwell 1996). Sustainability seeks to eliminate unnecessary waste including re-work. In this way it can be seen to accord with re-engineering principles and waste minimisation philosophies. All these aspects require management procedures where plans are established, monitoring takes place which informs appropriate decision making. While this process is routinely followed during the construction phase for time, cost, quality and safety, it rarely follows that a post project evaluation is undertaken to learn from assessment of the project as a whole. Thus, a crucial opportunity for organisational learning is missed.

There is a growing awareness of the impact upon society’s long term future of the process of developing the built environment. Concepts of ‘sustainable design’ and ‘sustainable construction’, which are part of a ‘green building’ agenda, are becoming more important to customers and clients who wish to appear supportive of, if not actually practising principles of sustainability. This requires designers and all parties of the development process to learn from past lessons and best practice principle, to promote and develop a sustainable built environment. Levin (1997) lists common features of ‘green building’ as practised in the USA. These include:

- energy conservation features, both passive and active in terms of energy efficient equipment;
- water conservation features including low consumption and use of ‘grey’ or recycled water;
- low chemical emitting materials for improved air quality;
- less environmentally destructive site development to preserve natural habitats, protect excess water run-off and changes to water tables;
- on-site waste water treatment;
- reduced ozone and fossil fuel emissions;

- life-cycle assessment approaches to material use and recycling;
- regulatory environmental impact assessment of the total building;
- regulatory recycling and waste minimisation provisions for building materials and waste products.

Baldry (1997) describes the contribution that project managers can make in supporting 'green building' principles. He cites the project manager's influence *"… to plan a procurement and resource acquisition route which relies upon ethical and equitable commercial relationships and the pursuit of efficient resource conversion"*. Interestingly he cites the 1992 Maastricht Treaty provisions for a 'precautionary principle' relating to actions that should be undertaken to rectify environmental damage at source. He notes that raising enlightenment amongst designers and constructors to meet or exceed the treaty's provisions is somewhat tempered by stakeholders' needs but he indicates that there is a clear responsibility to actively monitor the development and actualisation of environmentally sustainable design and construction. Baldry identifies the project manager as one independent team member that can exert influence of the design, monitoring and control to improve sustainability. His raising of ethical issues lends weight to the argument that building owners and clients are missing an opportunity to contribute to improvements to the environment in which we all share. This supports the view that organisational learning about the impact of construction upon the natural environment is important. Perhaps enlightened clients could specify in their terms of engagement that their project manager, as an independent professional, could lead the process of undertaking a post project evaluation.

Numerous tools exist for undertaking an evaluation of various aspects of 'green building'. Graham (1997) provides a comprehensive analysis of eight tools and systems used to measure and assess various aspects of environmental impact. He concludes that these tools can be constructively used to model likely impact upon the environment for proposed design and construction strategies. Yates (1997), agrees and provides an interesting analysis of six years of use of The Building Research Environmental Assessment method (BREEAM) which was developed in the UK. The tool also links cost savings with environmental impact. He cites a study of 100 interviews undertaken by the Deloite and Touche Consulting Group, which reveals interesting user motivations. Interviewees comprised a range of BREEAM current and potential users who discussed reasons for using the system. General societal goals, such as ensuring that best 'green building' practices are being applied, and more client specific goals, such as direct cost/benefit gains made from applying 'green building' principles, were cited. While Yates has a commercial interest in promoting the use of BREEAM specifically, it is interesting that large numbers of clients and building owners are concerned about 'green building' issues and are willing and keen to apply them.

Discussion

This paper highlights the need for improved production through both incremental productivity improvement (*kaizen* and innovation) and break-through improvements (business process improvement). Improvement in terms of sustainable construction was also discussed and it was strongly argued that there is a pressing need for practical ‘green building’ principles to be applied such as waste reduction, reduced re-work and other benefits that can be derived from buildability or constructability principals being applied. Other environmental improvements can also be gained to profit not only the building owner or client but also society at large. Sustainability issues were discussed to shed light on the value of this in terms of the contribution to organisational learning and how this can be translated in improvements for users and society.

Research reported on by Walker and Sidwell(1996) and Walker (1997a) indicates that of 75 projects investigated only six had formalpost project evaluations undertaken. Of these six, all were the process engineering projects. This indicates that building and civil engineering clients are not requiring such studies to be undertaken. It was argued that this may deprive all stakeholders of valuable organisational learning which can be used to improve productivity, innovation and adherence to ‘green building’ principles.

Continuing systemic change (for the better) is dependent upon building a permanent learning capacity across as well as within organisations (Kochan and Useem 1992, p404). While project teams tend to be temporary organisations they are made up of individuals who form more permanent teams within their own companies. Clients also tend to have more stable organisations. It has been clearly argued that organisational learning has the capacity to significantly raise productivity. It has also been strongly argued that systematic, codified and structured post project review can reveal valuable lessons, which may be successfully applied or suitably modified to improve productivity in future projects.

There is a stark contrast between a shallow, unstructured and ill-conceived process for harvesting lessons learned from any project and a well-structured and rigorous examination of the ‘history’ of a project. On the one hand lessons learned may be forgotten or transformed in the minds of participants well past a point of shared understanding. On the other hand, not only lessons learned, but also the context surrounding events and the richness of input from numerous points of view can be harvested and put to productive use.

Conclusions

There are few (if any significant numbers of cases) where the client demands, funds, and ensures that harvesting of knowledge gained from one project is available for the next. Various attempts to achieve these aims through partnering or strategic alliances are not addressing the main need - organisational learning.

A number of examples of ways in which organisational learning can be achieved has been offered through post project evaluations and ‘Design by Walking Around’ techniques. Both of these require to be undertaken through deep thinking and analysis rather than shallow or superficial analysis of problems tackled, approaches taken, circumstances surrounding problems and solutions, and strategies or tactics employed.

Clients have the capacity and the means to provide leadership in organisational learning through demanding well conducted reviews of projects to record and communicate lessons learned. The cost of including this requirement is unlikely to be significant, hardly a fraction of a percentage point of project cost. Benefits to be gained from such an exercise can be lasting and significant to the client and project team members.

Identification of environmental risks and their impact on procurement of construction works

R.W. Craig
Department of Civil & Building Engineering, Loughborough University, England

Abstract
This paper considers the risks by examining the 'controls' imposed by common law on the activities of developers and contractors in their relationship with environmental concerns. The risk is that a control is exercised so as to impose liability on the developer. The term 'developer' is used to describe both entities, which of course in reality may be the same or separate legal persons. The developer inevitably has the status of 'landowner' during the development phase, whereas the contractor probably does not, being merely a 'licensee' of the site.

The paper first examines two recent judgments in the House of Lords to show how the common law has not evolved to protect the interests of neighbours and local residents from the perils and hazards of property development which result in environmental deterioration. The conclusion is drawn that common law provides little control of development activity and inadequate remedy for those injured by environmental deterioration as a result of development. The common law protects only the enjoyment of the adjoining landowner or those injured by the developer's negligence. From the developer's perspective beyond the adjacent landowner, only the criminal law poses any real sanction for environmental deterioration. These substantial risks of criminal liability, which cannot be insured against, require identification and quantification at the procurement stage in the project cycle.
Keywords: Common law, damages, development, environment, liability, negligence, nuisance, Rylands v Fletcher

1 Introduction

It seems that there is inevitably some conflict between the interests of developers and the population affected by development, who may be simply the neighbours, the local community or a much wider community. The common law has restricted the activities of developers where those activities impact on others beyond the site boundary and developed remedies where property, economic or personal rights are damaged. But does the common law generally provide sufficient protection and remedy from environmental deterioration caused by developers? What risks does the common law create that developers need consider during the procurement process?

2 The common law

The common law has created three control or regulatory processes that might provide a remedy for a plaintiff who alleges that the quality of its environment has deteriorated due to property development: negligence, nuisance and the rule of *Rylands v Fletcher.* [1]

2.1 Negligence

The modern law of negligence is largely a creation of the common law courts during the last seventy years. The original policy of the law was simple, yet so much litigation on this theory has taken place. Each person was required to consider its own actions with respect to the impact that action might have on its neighbour, and to refrain from those actions which could reasonably be foreseen as likely to injure that neighbour. Inevitably the question arises: who is to be classed as a 'neighbour' in the circumstances in question? The answer originally provided was that a neighbour was any person who the law recognised as entitled to be considered as likely to be affected by the act, or acts, or omission, which are called in question.[2] Negligence is a tort (civil wrong) designed to provide, within limits, reparation for those injured by the carelessness of others. A negligence claim arises only on actionable damage. Much judicial time has been concerned with restricting the scope of duties owed, the extent of compensation allowed, the size and composition of the class of persons entitled to claim compensation, and the permitted time lapse between careless act and consequent damage. Recent policies of the English court have tended to restrict the scope of negligence claims, but this policy has not been adopted in other Commonwealth jurisdictions.

A plaintiff may have difficulty in establishing the degree of 'fault' necessary to secure compensation. Both private nuisance and *Rylands v Fletcher* avoid this problem by imposing the so-called 'strict' liability. Negligence is not further discussed in this paper.

2.2 Private nuisance

The law of private nuisance was reviewed by the House of Lords in *Hunter and others v Canary Wharf Ltd, Hunter and others v London Docklands Development Corporation.*[3] It is necessary to state the factual background. That part of the River Thames between Limehouse Reach and Blackwall Reach and known to previous generations as the West India Docks used to be the thriving Port of London, but it fell into disuse with the growth in container traffic from the East coast ports. The riverside land became derelict and remained so until the Secretary of State approved[4] a scheme which designated the Isle of Dogs, including Canary Wharf, as an 'enterprise' zone. Under this arrangement virtually any scheme could be constructed by-passing the normal process of development control. An agreement was concluded in July 1986 between LDDC[5] and Canary Wharf Ltd which resulted in the construction of office buildings, including the César Pelli tower, 250 metres tall, on plan about 50 metres square, and clad in stainless steel, together with associated infrastructure works. A new road was constructed, the whole redevelopment process causing much excavation and movement of spoil over a construction period of four years.

The essence of the 'enterprise' zoning was that the normal statutory controls on development were eased or removed altogether thus attracting private property investment funds. Before 1980 and the introduction of enterprise zones, it seems unlikely that development on the scale of Canary Wharf would have taken place without a public enquiry[6] and the opportunity created for local residents to voice their concerns. It may generally be said, that local concerns were overridden in this case pursuing instead the Government's view of the national interest.

The quality of the local environment must have been severely diminished for local people during the main construction phase. In Lord Hoffmann's words:

> "The local residents complain that the construction of the Canary Wharf Tower and the Limehouse Link Road caused them serious disturbance and inconvenience. Firstly, the construction of the road caused a great deal of dust in the air which settled upon their homes and gardens. If they opened their windows, everything in the room was soon covered in a layer of dust. If they hung out the washing in the garden it became dirty again. Secondly, the Canary Wharf Tower interfered with television reception. The great metal-clad tower stood between the BBC transmitter at Crystal Palace in south London and a swathe of houses, mainly in Poplar to the north of Canary Wharf, which lay in the building's electromagnetic shadow. The effect was that many houses could not receive television at all. In others, the quality of the signal was impaired. This state of affairs continued until April 199 1, when the BBC brought a relay transmitter into service. Between July 199 1 and August 1992 the residents had their aerials aligned to the new transmitter and the problem was thereby solved."[7]

The local residents commenced two separate actions against the developers and LDDC. The first action (the 'television action') against the developers was founded on negligence and nuisance and sought compensation for the tall building's interference with television reception. This action failed and is not further discussed. The second action (the 'dust action') sought compensation from LDDC for damage and annoyance caused by dust from the construction operations and was founded on, inter alia, nuisance. There were 690 residents as plaintiffs in the 'television action', and 5 13 in the 'dust action'. The claims had been raised by a substantial group of local residents, including householders who had the exclusive right to possess the places where they lived, whether as freeholders or tenants, or even as licensees. The group included people with whom householders shared their homes, for example as wives or husbands or partners, or as children or other relatives. All of these people claimed damages in private nuisance, by reason of interference with their television viewing or by reason of excessive dust. The court addressed the following question as a preliminary issue of law. Does a plaintiff in an action for private nuisance need to have an interest in the property in question, and if so, what interest?

Lord Lloyd observed that private nuisances are of three kinds. They are nuisance by encroachment on a neighbour's land; nuisance by direct physical injury to a neighbour's land; and nuisance by interference with a neighbour's quiet enjoyment of his land. The basis of a cause of action in nuisance is damage to the land itself. The measure of damages is usually the diminution in the value of the land caused by the damage complained of. That loss is suffered by the owner or possessor of the land. The quantum of that loss was not affected by the number of people on the land. Each member of a family did not have a cause of action: there was only one potential cause of action per home.

It was not disputed that activities which cause dust on a person's property could amount to an actionable nuisance, but who can sue? The traditional answer, said Lord Hoffmann, is that as nuisance is a tort against land, including interests in land such as easements and profits, a plaintiff must have an interest in the land affected by the nuisance. That interest was characterised as 'possession or occupation'. A series of cases over the years have explored the quality of possession or occupation needed to found a claim in nuisance. Lack of title to the land was overcome by a lengthy period of occupation. Wrongful possession against the true owner's interest was sufficient to found an action in trespass or nuisance against a third party. Exclusive possession by the plaintiff was a feature of all the actions in nuisance.

Actions in nuisance should not be confused with actions in negligence. Lord Hoffmann said that negligence was based on *fault* but protected interests of many kinds, whereas liability in nuisance was *strict* but protected only interests in land. The effect of the liability in nuisance being strict, that is independent of any fault, is that it is no defence to a nuisance claim to say that all care was taken not to commit it. The liability arises out of the invasion of the proprietary or other interest in land. [8] The exceptions to these well established principles lay in a Canadian case[9] which had been followed by the Court of Appeal.[10] But there was no good reason of policy why the old rules should be abandoned. Lord Hoffman did not agree with academic writings that had recently suggested that the law on this point should adapt to modern social conditions. On the contrary, any "development of the common law should be rational and coherent. It should not distort its principles and create anomalies merely as an expedient to fill a gap." Without an interest in the property affected by dust, said Lord Hoffmann, the plaintiff residents had no right to sue in nuisance.

The majority of the court were of the view that there was no good reason to depart from the law of nuisance as established in the authorities. A mere licensee had insufficient status to sue in private nuisance. An action in nuisance is only possible by a person who has the right to exclusive possession of the property affected. This means that co-habitees, partners, family members and lodgers without more than a license to occupy property are deprived of any right to sue a developer who harms the environment for such class of persons.

One voice of dissent was heard, that of Lord Cooke. In His Lordship's view the choice being made here was a policy choice, whether to restrict the law of nuisance to its historical position or let it expand at least with respect to who could sue. The law of nuisance had been established before the age of television and radio, motor transport and aviation, town and country planning, a 'crowded island', and a heightened public consciousness of the need to protect the environment. All these were among the factors now falling to be taken into account in evolving the law. It seemed absurd to Lord Cooke that whilst a husband as owner had standing to sue, his wife's occupancy of the matrimonial home was insufficient to found an action in nuisance. Children too should be entitled to relief from substantial and unlawful interference with amenities of their home. He noted developments on the law of nuisance within the USA. Here it was acknowledged that occupancy was a sufficient interest in itself to permit recovery for invasions of the interest in the use and enjoyment of the land.

> "Thus members of the family of the possessor of a dwelling who occupy it along with him may properly be regarded as sharing occupancy with intent to control the land and hence as possessors, as defined in § 328E. When there is interference with their use and enjoyment of the dwelling they can therefore maintain an action for private nuisance. Although there are decisions to the contrary, the considerable majority of the cases dealing with the question have so held."[11]

More recently in *Bowers v Westvaco Corp*[12] family members, including minors living at home, were awarded damages by the Supreme Court of Virginia for dust and vibration nuisance caused by truck-staging operations on adjacent property.

Lord Cooke attempted, in vain, to show that whilst it was accepted that in order to sue in the tort of nuisance it was necessary that the plaintiff have some link with the land. But the court was yet free to define the precise nature of that link. He could see that the adoption of his view might "add marginally to building or operating costs" but that was not an obstacle in adopting "reasonable safeguards in any other field of the law."

2.3 Rylands v Fletcher liability

The liability under the principle of *Rylands v Fletcher* was examined by the House of Lords in *Cambridge Water Co Ltd v Eastern Counties Leather plc*.[13] Eastern Counties Leather (ECL) was incorporated in 1879, and since that date has continued in uninterrupted business as a manufacturer of fine leather, employing about 100 people, all or whom live locally. It has used solvents in that process since the early 1950s, including PCE (perchloroethene) which has increasingly been in common, widespread and everyday use in dry-cleaning, in general industrial use (eg as a machine cleaner or paint-thinner), domestically (eg in 'Dab-it-off') and in tanneries. PCE is highly volatile, and so evaporates rapidly in air; but it is not readily soluble in water. ECL began using PCE sometime in the 1960s, and continued to use PCE until 1991. The amount so used varied between 50,000 and 100,000 litres per year. The solvent was introduced into what were (in effect) dry-cleaning machines and must have leaked into the ground.

Meanwhile, in the later 1970s concern began to be expressed in scientific circles about the presence of organic chemicals in drinking water, and their possible effects. The Directive (80/778/EEC) relating to the Quality of Water intended for Human Consumption was issued on 15 September 1980. UK regulations were made in 1989.

The prescribed maximum concentration values for PCE has been 10μg/litre since 1 September 1989. The United Kingdom values have been brought back into harmony with the WHO Tentative Guideline Values of 1984. Before publication of these papers little was known about this subject.

Cambridge Water Company's (CWC) claim against Eastern Counties Leather (ECL) for contamination of percolating water caused by leaking solvent (PCE) was based on three alternative grounds: negligence, nuisance and the rule in *Rylands v Fletcher*. The trial judge dismissed CWC's claim on all three grounds-on the first two grounds, because ECL could not reasonably have foreseen that such damage would occur, and on the third ground because he held that the use of a solvent such as PCE in ECL's tanning business constituted, in the circumstances, a natural use of ECL's land. The Court of Appeal, however, allowed CWC's appeal from the decision of the judge, on the ground that ECL was strictly liable for the contamination of the water percolating under CWC's land, on the authority of *Ballard v Tomlinson*.[14] It was against that decision that ECL appealed to the House of Lords. The question considered by the House of Lords was whether foreseeability was an essential element of liability under the principle of *Rylands v Fletcher*.

In order to consider the question in the present case in its proper legal context, it was desirable in Lord Goff's judgment to look at the nature of liability in relation both to the law of nuisance and the rule in *Rylands v Fletcher*, and for that purpose to consider the relationship between the two heads of liability. Since there is a close relationship between nuisance and the rule in *Rylands v Fletcher*, Lord Goff first considered whether foreseeability of damage is an essential element in the law of nuisance.

The principles of the law of nuisance have been discussed above. Lord Goff noted the original view of nuisance as a tort to land and that it had been distorted by cases involving claims for personal injuries which should have been brought in negligence. Historically nuisance was a tort of strict liability. When Blackburn J had given judgment in *Rylands v Fletcher* he had not regarded it as a revolutionary decision. He was not stating new but existing law, as is apparent from his judgment He was concerned in particular with the situation where the defendant collects things upon his land which are likely to do mischief if they escape, in which event the defendant will be strictly liable for damage resulting from any such escape. It followed that the essential basis of liability was the collection by the defendant of such things upon his land; and the consequence was a strict liability in the event of damage caused by their escape, even if the escape was an isolated event.

The strictness of liability in nuisance had been reduced by the concept of 'reasonable user'-the principle of 'give and take' as between neighbouring occupiers of land. If the user is reasonable, the defendant will not be liable for consequent harm to his neighbour's enjoyment of his land; but if the user is not reasonable, the defendant will be liable, even though he may have exercised reasonable care and skill to avoid it. Strikingly, said Lord Goff, a comparable principle had developed which limited liability under the rule in *Rylands v Fletcher*. This was the principle of 'natural use' of the land. The unnatural use arose when that use involved increased danger to others. Then the defendant would be liable for the harm suffered by the plaintiff, notwithstanding that he has exercised all reasonable care and skill to prevent the escape from occurring.

The liability in nuisance is strict, but subject to the principle of 'reasonable user'. But it by no means followed, said Lord Goff, that the defendant should be held liable for damage of a type which he could not reasonably foresee; and the development of the law of negligence in the past sixty years points strongly towards a requirement that such foreseeability should be a prerequisite of liability in damages for nuisance, as it is of liability in negligence. Foreseeability was an essential element in determining liability in public nuisance for the spill of oil in Sydney Harbour.[15] In Lord Goff's judgment, the law was settled to the effect that foreseeability of harm is indeed a prerequisite of the recovery of damages in private nuisance, as in the case of public nuisance.

Lord Goff turned to consider the matter of foreseeability as an element in liability under ***Rylands*** *v Fletcher*. The general tenor of Blackburn J's statement of principle was that knowledge of the risk, or at least foreseeability of the risk, is a prerequisite of the recovery of damages under the ***Rylands*** principle. But the ***Rylands*** principle is one of strict liability in the sense that the defendant may be held liable notwithstanding that he has exercised all due care to prevent the escape from occurring. Lord Goff concluded that the historical connection of ***Rylands*** liability with the law of nuisance must now be regarded as pointing towards the conclusion that foreseeability of damage is a prerequisite of the recovery of damages under the ***Rylands v Fletcher*** rule. The recovery of damages in private nuisance depended on foreseeability by the defendant of the relevant type of damage. It was logical to extend the same requirement to liability under the rule in ***Rylands v Fletcher.***

Should ***Rylands*** be developed by the courts as a principle of strict liability for damage caused by ultra-hazardous operations, on the basis of which persons conducting such operations might properly be held strictly liable for the extraordinary risk to others involved? The cost of such damage would then be absorbed as an overhead of those engaged in the hazardous activity, rather than impose it on the injured person, its insurers or the wider community. This appeared to Lord Goff to be the trend in the USA.[16] But as a general rule, it was more appropriate in His Lordship's view for strict liability in respect of operations of high risk to be imposed by Parliament, not by the courts. If such liability is imposed by statute, the relevant activities can be identified, and those concerned can know where they stand. Furthermore, he added, statute can where appropriate lay down precise criteria establishing the incidence and scope of such liability.

Returning to the instant case, all the ingredients were present to hold ECL liable in nuisance and under the principle of ***Rylands.*** But when ECL created the conditions which have ultimately led to the present state of affairs-whether by bringing the PCE in question on to its land, or by retaining it there, or by using it in its tanning process—it could not possibly have foreseen that damage of the type now complained of might be caused thereby. Indeed, long before the relevant legislation came into force, the PCE had become irretrievably lost in the ground below. In such circumstances, Lord Goff did not consider that ECL should be under any greater liability than that imposed for negligence.

His Lordship added that the present case might be regarded as one of historic pollution, in the sense that the relevant occurrence (the seepage of PCE through the floor of ECL's premises) took place before the relevant legislation came into force; and it appeared that, under the current philosophy, it was not envisaged that statutory liability should be imposed for historic pollution. If so, said Lord Goff, it would be strange if liability for such pollution should arise under a principle of common law. Since those responsible at ECL could not at the relevant time reasonably have foreseen that the damage in question might occur, the claim of CWC for damages under the rule in *Rylands v Fletcher* failed.

3 Conclusion

The common law controls on the developer who causes deterioration in the neighbourhood's environment are found to be less than adequate to afford the degree of protection generally required. Negligence requires proof of fault which is difficult to establish. Both nuisance and *Rylands* liability are said to be 'strict' and independent of fault, but require foreseeability of damage caused as a prerequisite to liability, and that so-called 'strict' liability is subject to relaxations—that of 'reasonable user' in nuisance cases, and that of 'natural use' of land in *Rylands v Fletcher* cases. Legal standing to sue in nuisance exists only for the person with exclusive right to possession of the affected property. A mere licensee has no such right. Society beyond the adjacent landowner had better look to statutory regulation for protection from, and sanctions against environmental deterioration. Developers need fear little in the common law beyond the immediate adjacent landowner. Only sanctions in criminal law pose any substantial risks.

Construction Projects: the Culture of Joint Venturing

R F. Fellows
Department of Architecture and Civil Engineering, University of Bath, Bath, UK

Abstract
This paper considers the diversity of project procurement approaches which exist in most countries' construction industries as, essentially, a spectrum of joint venture arrangements. In striving for performance improvement, the underlying objective is considered to be participant satisfaction, subject to a power hierarchy. Participant goals are critical in determination of goals for a project; these are subject to major cultural influences in both their determination and communication. Transaction costs are employed to consider the costs of forming and pursuing relationships between project participants; such governance costs are supplemental to the neo-classical production costs. It is concluded that cultural considerations are vital to development of accepted project goals and that such goals are critical in obtaining efficient and effective performance to secure participant satisfaction.
Keywords: Culture, goals, joint ventures, participant satisfaction, procurement, transaction costs.

1. Introduction

The issue of selecting the most appropriate method of procuring a construction project remains a fundamental decision for both clients and members of the construction industry. Much effort has been and remains devoted to quantifiying differentations between procurement 'systems', often to the exclusion of examination of commonalities and the elicitation of participants' requirements - both criteria and parameters. Ireland [1] alluded to the potential fallacy of extensive procurement system differentiation.

In essence, all procurement approaches involve some form of joint venture - from the often individual (organisation) orientation of the fragmented, 'traditional' TMO (temporary multi organisation) approach [2] to the collaborative formalities of integrated procurement - notably the BOT 'family', partnering and formalised joints ventures.

In tandem with analyses of performances of, especially major, projects, there are suggestions that critical success factors (CSFs) may exist. Unfortunately, there appears to be considerable oversight of assumptions inherent in CSF analyses, most notably that success depends on circumstances, perspective and goals. What may be successful for one project participant may be a disaster for another! Further, while success concerns a (comparative) evolution of performance, it is likely that a more fundamental variable is participant satisfaction - performance as perceived by the participant under examination.

Thus, the organisational processes of project procurement (a managerial 'how'?) constitute a medium - an intervening, contextual variable - for performance achievement and goal realisation.

2. Procurement

Procurement choice requires analysis of three dimensional matrix and, although a set of decision phases which occur at discrete times of a project in practice, preferably should be evaluated holistically at project conception/inception. However, a significant inhibitor is the (lack of) development of project (performance) goals.

The main dimensions of the matrix array project participants, participant relationships and project performance variables. It is helpful to adopt a functional approach in drawing up the matrix and proceeding with its evaluation [3]. Clearly, the earlier the evaluation occurs the greater is its potential effectiveness.

Procurement may be viewed from a systems perspective as involving a chain of client, design and construction functions. Environmental controls are moving variably in UK - the well-known vagaries of politics, economics and social factors - but with 'technical' controls of 'town planning', 'building control' and 'environmental control' moving differentially (e.g. more flexible building control but increasing anti-pollution and safety regulations); reflecting almost global trends which commenced in the late 1970s.

In UK and similar societies, much analysis of procurement has focused on selection of the main contractor. Although published clients' guides to procurement - e.g. [4] incorporate selection of designers as well as constructors, their assumptions of applicable performance criteria are rather confused and so, may detract from the determination of more appropriate criteria for individual projects. Further, by concentrating on criteria, attention to parameters and to value management possibilities may diminish.

Thus, procurement brings together technical project performance possibilities, (interpreted) legislative requirements of the project environment with the human-based (for major projects) organisational requirements and the personal characteristics of the decision takers within their evolving power structure(s). Economic, political, social etc. factors become internalised in project decisions by their impacts on criteria and parameters, thereby constituting constraints on subsequent decisions and actions.

3. Joint Ventures

Joint ventures are ‘characterised by oligopolistic partners’ [5]. In construction, formal joint venturing is increasingly common on major, especially international, projects.. In developing countries, many major projects are aid funded (directly by project finance or indirectly via country finance, the latter being preferred by the world bank etc.) which may involve ‘tie-backs’ to donor countries; involvement of local organisations - many nations require local involvement via joint venturing to promote ‘technology transfer’ - extends the scope of joint venture arrangements and adds a further dimension to the joint venture decision by the overseas partner(s). In the absence of a requirement for joint venturing, joint ventures occur as amalgamations of participants due to project size or technologies, translatable into risk perceptions and resourcing requirements.

Formal joint ventures may be project-based or ‘strategic’, i.e. formed for a particular project only or established as a continuing association of the participants; project joint ventures tend to be more opportunistic and relatively casual in their establishment - whereas a strategic joint venture is likely to be a separate company under the ownership of the joint venturers. Thus, the linkages between even formal joint venture participants are of differing degrees of permanence and legal relationship constructs.

Widely, construction projects are portrayed as team efforts, implying thereby significant components of joint venturing. However, all but formal joint venture procurement arrangements involve a complexity of buyer-seller relationships concerning the provision of design and construction services and products through direct and sub contracting relationships. Thus, the purported team identity has been characterised more appropriately as a TMO or coalition [6].

In order for a teamwork situation to exist on a project, there must be a goal or set of goals which are acceptable to the project participants. Given such knowledge, risk apportionment can be developed appropriately and explicitly such that the accepted (via contracts entered) performance requirements are not used merely as a basis to secure work and from which return enhancements are sought rigorously (claims etc.). Whilst it is clear that current work allocation and contract mechanisms, via ‘tender’ and contract terms, set out performance requirements explicitly in return for the price bid (acknowledging permissible adjustments), there is no evidence, anecdotal or otherwise, that such requirements are derived from and compatible with project goals.

4. Goals (and parameters)

‘Prospective partners should have a clear understanding of one another’s goals and objectives in establishing a joint venture. While different parties will invariably have different objectives, these must not be contradictory. It is important therefore, that the priority goals of each party be specified and be understood by all partners from the outset' [7].

Many researchers view organisations as goal oriented, social conglomerates e.g. [8], [9]. The perspective is reinforced by others who regard organisations as systems which co-ordinate people and other resources to achieve performance goals [10], [11]. Porter [12] asserts that goals must be defined in order to focus 'the attention of individuals and groups (and) to provide a source of legitimacy for decisions!

Perrow [13] distinguishes official and operative organisational goals (analogous to the formal and informal project operational systems [14], [15], whilst Pervin [16] notes that goals are arranged in a (flexible) hierarchy. However, importances of goals in a hierarchy change with alterations in organisational power distributions. Managing organisational goals is a continuous process in which 'competing and conflicting priorities must be balanced' [17]. Thus, a hierarchical set of (project) goals is likely to be unstable due to the constantly varying power structure of construction TMOs.

Satisficing may be a necessary approach to achieving performance on multiple goal projects [18] (especially if some goals are mutually exclusive, if only in a maximising sense) however, overt satisficing may detract from higher levels of performance which a bounded competitive maximising approach by project participants could (otherwise) achieve. It is important to preserve the incentive facets of goals.

Organisations consist of groups which comprise individuals. The amalgamation of a number of discrete organisations into a TMO fosters exponential expansion of organisational and, hence, goal (determination and achievement) complexities. Generally, individuals relate to organisations as members of groups and, hence, are subject to particular cultural influences and influences through sentience etc. Thus, the interactions and interdependencies, between a project TMO and the individuals working in it are filtered through the discrete organisations and groups [11], [19], [20]. Such effects are reinforced by indexicality (meanings/understandings being dependent upon socialisation, education, training etc.) and rules/codes as well as norms of behaviour for the variety of professional and other groupings [21].

Goals impact on both product and process - on product in determining what is sought and, thence, demanded; on process by influencing performance in supplying the product (project outputs). Peoples' behaviours are determined by goals, self-efficacy (their perceived performance capabilities) and motivation, stimulated by the organisation's expectations and subject to situational constraints [22]. Behaviour can be examined as a vector, having magnitude and direction, which has both cognitive (thought process; 'rationality') and affective (emotion) components [23].

Four major determinants which related goals to performance outcomes:

- legitimate authority of the goal setter
- peer and group pressures towards goal commitment
- participants' expectations (that effort leads to performance)
- incentives and rewards (to enhance commitment to goals) [24].

Naturally, communication of goals is essential if the goals are to operate for performance achievement.

A particular issue for construction is not only the identification of participants' goals but their combination to yield project goals. For UK building projects, not only are most clients poor in providing briefing information (understandable, as most clients are 'naive') but architects are poor at obtaining the information necessary for a good project brief from clients [25]. Further, '..the tradition persists whereby the architect prepares a sketch plan from which the other consultants work. Frequently alone and, often, in a matter of hours, the architect arranges spaces in a structure using predominantly aesthetic criteria' [26].

Thus, the determination of, even, client goals regarding projects is questionable. Designers have a vital but difficult task of determining the clients needs (which may involve identifying the client(s)) usually expressed in terms of the client's business and translating those needs into a design, likely to meet those needs, compatible with design inputs of other designers and realisable by the constructors; all within parameters set by (or agreed with) the client and regulating authorities!

Clearly, early involvement of primary participants will reduce the need to forecast (rationally assume) those organisations' individual goals and facilitate agreement of realisable project goals with acceptable degrees of (in)compatibility. In practice, project participant involvement is staged progressively and design proceeds iteratively to yield progressive fixing of goals and setting (conversion of criteria into) parameters (e.g. specification, total project cost, duration) which are imposed on following participants' inputs or, if essential, changed with difficulty and costs.

5. Culture

Culture has been defined in a vast number of ways - from 'the way we do things' to the dimensioning of, 'The collective programming of the mind which distinguishes one group from another', using four dimensions; consideration of organisational cultures employs six dimensions [27]. Further, how culture is regarded, and, hence, may be 'employed' falls into two main arenas - as a 'tool' or as a 'method'; Smircich [28] echoes the dichotomy for organisational cultures - as something which an organisation has or something which an organisation is.

Human behaviours - individual and various levels of collective - suggest that the cultural groupings and strata (organisations, professions, etc.) are likely to be self perpetuating. The difficulties of changing beliefs, an underpinning of behaviours, indicate that changes will be peripheral and slow to occur. Cultural indicators – symbols (notably, language), icons/heroes, behaviours etc. can be observed to suggest the underpinning beliefs which are ordered into a hierarchical value structure; an obvious problem is the 'cultural colouring' imposed by the observer and the research instrument(s) employed.

Construction organisations to be flexible in order that they survive and be successful [29]. The informal system – used for project operation – is highly adaptive with participants bringing their knowledge and experience to assist the interpretation of the formal system's constituents [14],[15]. For UK, 'The culture of the industry has been evolved by members in order to deal with its economic reality. Any attempt to change culture, which does not also tackle the problems which gave rise to it, stands little chance of success' [30]. Clearly, the 'technological' sub-systems are subjugated to the economic system such that 'business imperatives' operate.

6. Transaction costs

Transaction costs comprise, 'the running costs of the economic system', [31] and, as such, constitute various elements of friction in an economy. They may be classified as *ex ante* and ex *post* agreements (via contracts) 'governing' the transaction(s) in question [32]; *ex ante* costs are those pertaining to drafting, negotiating and safeguarding relationships, whilst *ex post* costs involve costs of post contract problems (what occurs is at variance with what the drafters intended) and their rectification (however achieved – including arbitration and litigation) and the cost of bonds etc. required in attempting to make the agreement (assurance of having obligations fulfilled) more secure. Clearly, the two categories of transaction costs are interdependent - normally, an inverse relationship.

Ownership of real property involves not only rights to primary (ownership) title but, in general forms, use rights, appropriation of returns rights and alteration rights. In terms of construction supply, (normally) the suppliers are given use and adaptation rights by the primary owner in return for a pre-determined sum. However, in arranging the supply mechanism, distributions of appropriation rights in recompense for use rights and adaptation duties form the focii of transactions; in establishing distributions of such rights and duties, bargaining is widespread but within various power paradigms [33] and subject to bounded rationality [18].

Hence, agreements are reached and, logically, are intended to deal with perceptions of participant objectives and behaviours and environmental influences under conditions of uncertainty. Therefore, the objectives of *ex_ante* actions are to predict and control, within the objectives of the particular organisation (short term/ long term) the *ex* post situation – notably expected costs and returns.

Most commonly, economic analyses focus on profit maximisation or, given a price (such as consequent upon tendering), cost minimisation. Adopting an holistic view of the provision of a good or service (e.g.. a construction project), the objective involves minimisation of both production and transaction cost. Benefits (e.g. price reduction) of large number *ex ante* competition are likely to be eroded by *ex post* 'quasi monopoly'.

Standard form contracts and 'normal' procurement arrangements have evolved reactively in construction; use of off-the-shelf *ex ante* documents etc. may reduce both cost categories but increasing adaptation of standard forms, notorious *ex post* opportunisms and new procurement approaches testify to difficulties [34], [35].

Increasing attention to value chain approaches in construction, attention to clients' perceptions of value and realisation of equal technical abilities amongst pre-selected suppliers and recognising interactions of 'process efficiency' and "product effectiveness' shows the importance of transaction costs in determining appropriate organisational structuring via considerations of (inter-) organisational governance.

'. . . as transactions become more idiosyncratic.. vertical integration will . . appear ..' [32]. Although, in construction, almost all projects are bespoke and operate under joint venture characteristics, indiosyncratic projects can be seen as involving exceptional risks (size, finance, location, technology etc.; individually but usually, in combination). Often, such idiosyncratic projects are undertaken by formal joint ventures. Formal joint ventures may be required by a host country to assist its development. Normally, only size factors induce horizontally combinations, the remainder involve vertical combinations – including the informal joint venturing of most construction projects.

7. Conclusions

The widespread striving for increasing efficiency and effectiveness of construction projects, most obviously by enhancement of common measures of project performance (in terms of time, cost and quality), can be secured only by attention to transaction costs as well as production costs. In tuning governance structures to facilitate holistic economies, attention must be paid to behavioural factors – the essence of cultural analysis.

Attention should be devoted to determining and communicating appropriate and acceptable project goals which should accord with performance criteria ancl parameters of the project and evolved to be compatible with goals of project participants. Only in such circumstances can holistic costs be minimised, taking account of cultural factors involved – notably those pertaining to bargains and relationships, including individual transaction versus long term perspectives.

Particpants' views of value are critical (exchange and use values). Consideration of costs alone – even if holistic and aimed at reduction – can provide partial analysis only.

Dispute Review Boards 1998: The Need to Stay on Track

R. J. Smith
Wickwire Gavin, P.C., Madison, Wisconsin USA

Abstract
A 1992-94 Construction Industry Institute (CII) study identified the elements deemed essential for a successful dispute review board (DRB). These finding and recommendations were reaffirmed in the Construction Dispute Review Board Manual, published in 1996. In the interim period, the use of DRB's has continued to increase, both in the U.S. and other countries. This trend is expected to continue. At the same time a variety of practices inconsistent with the recognized published norms have emerged. Some Employers/Owners--and some DRB members--apparently feel compelled to "tinker" with a well established process, contrary to the maxim of "If it is not broken, don't fix it." An example with potentially widespread implications is the World Bank required modification to FIDIC Red Book Clause 67, which has unrealistic timelines and compensation provisions. Problem areas emanating from other clauses and on a variety of projects include neutrality of DRB members, proposals for reducing the frequency of site visits, attempts to limit the jurisdiction of DRB's, long and complex pre-DRB procedures, a trend towards formal adversarial hearings, and unnecessarily long DRB recommendations. It is essential that all involved in the DRB process--specifier, employer/owner, and contractor--work to help ensure that the process is not so diluted, modified, or corrupted as to adversely impact its effectiveness. Otherwise, the resolution rate (over 99%) and attractiveness will markedly decline, which would be detrimental to the construction industry. This paper will identify the problems and propose solutions.
Keywords: Dispute Resolution, Dispute Review Boards.

1 Introduction

Variations from proven Dispute Review Board (DRB) practices may degrade the process and dilute its effectiveness. This paper reviews the characteristics widely deemed to be important for successful DRB usage. It then identifies some of the anomalies and variations that have been introduced and explains why the deviations from accepted practice should be avoided. The purpose of the paper is to encourage adherence to the norm and discourage unwarranted "tinkering."

2 Background

The Dispute Review Board, sometimes termed a Dispute Resolution Board (or Panel) or Dispute Adjudication Board, is a well established method of jobsite level construction dispute resolution. It has been used on several hundred contracts. Increased use is projected.

The essential and fundamental concepts of a Dispute Review Board are:

1. A panel of three impartial mutually-selected/approved individuals with expertise appropriate to the project, established at the beginning of construction.
2. Periodic site visits by the Board, including meetings with representatives of the parties.
3. Informal on-site hearings conducted by the Board, during which it considers documentation and oral statements/arguments of the parties relative to a particular dispute.
4. A written non-binding recommendation from the Board to the parties for resolution of the dispute.

The DRB is an alternative dispute resolution process that has been shown to provide four clear benefits:

1. Early attention to and informed objective evaluation of issues arising during contract performance. This provides a "reality check" on the parties' positions.
2. Prevention of some disputes and prompt business-like resolution of other disputes on an individual basis before they grow into larger problems or accumulate.
3. Cost effectiveness.
4. Facilitation/encouragement of cooperation between on-site managers for the Employer and the Contractor.

2.1 Generally

As the process name suggests, the purpose of a DRB is to <u>review</u> disputes after bilateral negotiations have reached an impasse. Such review takes place as early as possible after impasse is reached at the jobsite level. DRB involvement often follows a formal decision by an owner/employer designee such as an architect, engineer, or construction manager. The DRB's output is a written recommendation, normally non-binding. The

Board, which usually is comprised of individuals from several disciplines relevant to the project, obtains input for its recommendations from four basic sources:

- Project knowledge gained through periodic site visits and periodic informal on-site progress discussions with the parties.
- Receipt and review of job and progress meeting minutes.
- Prehearing statements of position on specific disputes.
- Informal hearings, usually held at the jobsite, with individuals having first-hand knowledge of the facts relative to the dispute and where copies of documents are provided to the Board.

The reported resolution rate of disputes submitted to DRB's exceeds 99 percent. Any action that modifies the flow of information can be detrimental.

2.2 Applications

The first generally recognized deployment of a DRB was for the second bore of the Eisenhower Tunnel in 1975.[1] For the next 10 to 12 years, major growth took place in the heavy and underground construction industry. Subsequently, it has been endorsed for -- and found widespread acceptance in -- building and process construction as well.[2] Currently the DRB has been used on heavy, underground, other civil, process, and building construction contracts in both the private and public sectors.

A sizable fraction of total DRB usage has been on projects under US$ 10 million, and over half of the DRB projects had a cost of less than US$50 million. Because a DRB provides a tangible but somewhat nonquantifiable benefit to any project, making this decision based on cost becomes essentially a subjective cost-benefit analysis. The cost of a DRB can be on the order of US$5,000-10,000 per meeting day. Assuming quarterly meetings of one to two days in length, the annual cost becomes US$20,000-80,000. Thus, on a US$lO million contract, the costs for DRB operations, exclusive of the involvement of the participants from the owner and the contractor, is 0.2-0.8% of contract price. Many consider this a very cost-effective investment, particularly when compared to the costs of arbitration and litigation.

2. In 1990, the Construction Industry Institute Dispute Prevention and Resolution Task Force undertook a study of the DRB process, which resulted in the publication of research results in 1992. Vorster, Michael C. *Dispute Prevention and Resolution: Alternative Dispute Resolution in Construction with Emphasis on Dispute Review Boards,* Construction Industry Institute, 1992.

3 Essential elements

In an extensive, multi-year empirical study of the DRB process supported by the Construction Industry Institute[3], Professor Michael C. Vorster of the Civil Engineering Department of Virginia Polytechnic Institute and State University and the CII Dispute Prevention and Resolution Task Force studied numerous Dispute Review Boards in action and additionally reviewed a variety of DRB contract provisions. This resulted in publication of a "Classic DRB Methodology Checklist." The components of this checklist are shown in the left hand column of Table 1. Explanatory comments and opinions of the author concerning the significance or practical application of these items are in column 2.

4 Observed deviations from recommended practices

Column 3 of Table 1 notes those features which have been observed to have been modified or not used at all.

5 Comments and recommendations on deviations

Column 4 of Table 1 briefly describes the anomalies and deviations and notes the considerations involved.

6 Other detrimental practices

6.1 Rigid time line

To be sure, prompt processing of disputes is important. However, some contract provisions, e.g., the World Bank's alternate to FIDIC Red Book Clause 67 has rigid limits. The DRB must schedule, convene and hold a hearing and issue its recommendation within 56 days of a request. Sometimes this is not practical or workable.

6.2 Jurisdictional limitations

Occasionally, a DRB specification will be written to limit the Board's jurisdiction. One such specification limited the DRB to only issues arising under the technical specifications. This is not prudent, for it may lead to disputes over jurisdiction.

---

3. A consortium of U.S. contractors, owners, engineers and universities.

7 Conclusion

While the deviations from the model that have been observed may be well-intentioned, there has been no showing that they are justified. Indeed, for the reasons stated in the table, these variations can be detrimental and should be avoided.

TABLE 1
CLASSIC DRB METHODOLOGY CHECKLIST
(AS DEVELOPED BY PROFESSOR M.C. VORSTER, VIRGINIA POLYTECHNIC INSTITUTE AND STATE UNIVERSITY, WITH 1998 COMMENTARY BY ROBERT J. SMITH)

"You may use this checklist to assess the compliance of a particular DRB with the classic methodology developed by UTRC [the ASCE Model]. There should be a positive response to all 22 statements."

Vorster Checklist Item	Smith Comment/ Opinion	Deviations/ Anomalies	Comments Noted by Smith and Smith Recommendations
CONTRACT REQUIREMENTS			
1. The intention to establish a Board is noted in the instructions to bidders.	This generally indicates an enlightened owner and is thought to encourage lower bids.	No	None
2. The provisions for establishing the Board are set out in the contract.	This enables both parties to understand their rights and responsibilities with respect to setting up the DRB, and usually requires early establishment.	No	It is of course possible to amend an existing contract to add a DRB

Vorster Checklist Item	Smith Comment/ Opinion	Deviations/ Anomalies	Comments Noted by Smith and Smith Recommendations
3. The provisions for establishing the Board do not preclude either the owner or the contractor from resorting to other methods for the final settlement of disputes.	In other words, the DRB output is not final or binding; no rights are surrendered.	No	Sometimes completion of the DRB process is a prerequisite to more formal or binding resolution.
MEMBER QUALIFICATIONS			
4. Board members are neutral, able to serve owner and contractor equally and have no conflict of interest.	This is critical to success.	Yes	Owners and Contractors sometimes nominate individuals with a known general tendency to favor their position. In addition, some members seem to be nominated only by Contractors. Further, when confronted with disputes, some DRB members take a results-oriented view which can lead to 2 to 1 recommendations, which are much less influential. It is recommended that reference checks and rigorous screening of nominees be undertaken.
5. Board members have acknowledged technical expertise in the type of work being undertaken.	This promotes **(1)** confidence that the Board members understand the facts, issues, and contract requirements, and (2) efficiency.	No	An effort should be made to select individuals with appropriate discipline experience.

Vorster Checklist Item	Smith Comment/ Opinion	Deviations/ Anomalies	Comments Noted by Smith and Smith Recommendations
6. Board members are respected by the owner and contractor for their impartiality and technical expertise.	This is critical to success; the mutual evaluation, selection, and appointment process assures this.	Yes	See comments for Item 4 above.
MEMBER SELECTION			
7. Owner and contractor have each nominated one Board member. These two members have selected the third member to act as chairperson of the Board.	This permits each party to "hand-pick" one neutral, subject to conflict of interest requirements and the other party's approval.	Yes	An acceptable alternative is for the Owner and Contractor to each offer a slate of three candidates acceptable to it, from which the other party may select one.
8. All parties agree on the selection and appointment of all Board members.	"Hands on" involvement in the process promotes confidence. This requirement tends to discourage a party from nominating one who might be perceived as an advocate. Rarely if ever is a nominee rejected, and then only for verv valid reasons.	No	None

Vorster Checklist Item	Smith Comment/ Opinion	Deviations/ Anomalies	Comments Noted by Smith and Smith Recommendations
OPERATING PROCEDURES			
9. Board members receive regular, written progress reports and remain informed on the status of the work.	These need not be special reports. Typically, the periodic (weekly or monthly) progress reports and progress meeting minutes which are prepared in the regular course of contract administration are quite satisfactory. The time required for Board members to review such reports is modest and not of significance from a fee perspective.	**No**	Occasionally the reports are received long after their initial issuance.
10. Board meetings are held on the job site at regular intervals, not exceeding four months.	This is critical, and the temptation to postpone or cancel meetings because there are no pending disputes should be resisted. This would be false economy, and deprive the DRB of the opportunity to continue to build familiarity with the project and its participants.	**Yes**	In an apparent effort to economize, the contract parties sometimes increase the interval between meetings to six months or more, or put the DRB in an "on-call" status. This is inadvisable. The DRB is deprived of the opportunity to develop an understanding of the project as well as the opportunity to develop rapport and mutual respect between it and the contracting parties, and vice versa.

Vorster Checklist Item	Smith Comment/ Opinion	Deviations/ Anomalies	Comments Noted by Smith and Smith Recommendations
11. Presentations to the Board are made by field project managers who are completely involved in the process.	First hand accounts are valuable.	Yes	Claiming parties will occasionally seek to have representation or participation by lawyers or consultants. With limited exceptions this should be discouraged. It almost necessarily results in the other party wanting to have the same level of outside assistance. This adds to the time and cost and gets away from the fundamental concept of the board considering disputes as they develop in the field.
CONDUCT OF HEARINGS			
12. Either owner or contractor is able to appeal any decision, action, order, claim, or controversy to the Board at any time.	It is presumed that good faith bilateral negotiations have been conducted. However, the practice of some owners of interposing numerous procedural prerequisites or levels of review before going to the DRB diminishes many of the advantages of the DRB.	Yes	Some contracts unfortunately have a protracted process before an architect or engineer decision. This becomes a barrier and should be avoided.

Vorster Checklist Item	Smith Comment/ Opinion	Deviations/ Anomalies	Comments Noted by Smith and Smith Recommendations
13. Both owner and contractor are adequately represented at all hearings; rebuttal and requests for clarification are permitted.	Adequate representation refers to "key players," not counsel. Experience has shown that principals know when they have said enough.	No	None
14. Board recommendations are in writing and are made directly to the project participants who are responsible for accepting, appealing or rejecting recommendations.	The written recommendation with rationale demonstrates the DRB's understanding of the dispute. The rationale/explanation helps persuade the disappointed party to accept the recommendation.	No	None
TIMING AND SEQUENCE OF EVENTS			
15. Board selection and appointment is made within eight weeks of notice to proceed with contract work.	Having the DRB in place early permits it to become acquainted with the project and its participants. Having it in place before disputes are likely to arise prevents posturing or vacillation regarding the process.	Yes	The delay in getting the board organized is perhaps the most frequently observed problem. Often it seems that it is the owner that is not prepared to act expeditiously. One method for combating this is for the owner to have a pre-qualified list of candidates available before contract award.
16. Appeals are made to the Board as soon as possible and the Board handles issues current at the time of appeal.	The "real-time" component promotes prevention and item-by-item resolution.	Yes	See comments for number 12 above.

Vorster Checklist Item	Smith Comment/ Opinion	Deviations/ Anomalies	Comments Noted by Smith and Smith Recommendations
17. Written recommendations of the Board and the reasoning supporting the recommendations are made available to the project participants within two weeks of an appeal.	Two weeks is desirable, but occasionally difficult to achieve. On the other hand, some recommendations can be issued in a matter of hours or days.	Yes	Two weeks is sometimes but not always possible. The parties should perhaps continue to use it is a guideline but recognize that exceptions will need to be made. Applying it rigidly could deprive the board of necessary analysis time.
LIMITATIONS OF AUTHORITY			
18. Board members do not act as consultants and do not give advice on the conduct of the work.	To do so would obviously compromise neutrality.	No	None
19. The Board does not usurp either the owner's or the contractor's authority to direct the work as provided in the contract.	The DRB's role is to (1) review and (2) make recommendations for resolution of disputes presented to it.	No	None
SUBSEQUENT PROCEEDINGS			
20. The recommendations of the Board are not binding and may be rejected by either owner or contractor.	This promotes focus on the most relevant evidence and facilitates informal procedures.	Yes	Occasionally DRB specifications are written so that the recommendation will be binding. This tends to increase the formality, length, and cost of hearings. Careful consideration should be given before this adopted.

Vorster Checklist Item	Smith Comment/ Opinion	Deviations/ Anomalies	Comments Noted by Smith and Smith Recommendations
2 1. The written recommendations of the Board and the reasoning supporting the recommendations are admissible as evidence in any subsequent dispute resolution procedure.	This is a very controversial issue with meritorious arguments on both sides.	Yes	This is perhaps the most frequently discussed and modified term in DRB specification. On the one hand, it is acknowledged the recommendation should be persuasive to a an adjudicatory body, such as a court or arbitration panel. On the other hand, there is a legitimate concern that DRB findings, typically based on unsworn testimony and hearsay that would not be admissible in a formal legal proceeding can be brought in through the "back door." The specification recommended in the Construction Dispute Review Board Manual permits admissibility of (1) the fact that there was a DRB; (2) the identities of the DRB members; and (3) the ultimate recommendation be admitted. In a sense this is akin to an expert witness opinion. Other DRB specifications say that the DRB output is admissible within the discretion of the adjudicatory body.

Vorster Checklist Item	Smith Comment/ Opinion	Deviations/ Anomalies	Comments Noted by Smith and Smith Recommendations
COSTS			
22. The cost of the Board is borne equally by the owner and the contractor.	This is consistent with the notion of the DRB being a neutral panel.	No	None

February 1998

Introduction

The Rio conference in 1992 and Rio II in 1997 clearly established a **new international** agenda and priorities in the area of environmental policy and strategy. Environment4 policies can no longer be regarded as optional, marginal or secondary to some other set of objectives. The 21st century will be marked by the implementation of a new paradigm that puts environmental issues at the heart of strategic, corporate and management planning (Whitelegg, 1997). There are several reasons why this major transformation has taken place:

- The immediacy and, urgency of global transport problems including climate change (global warming), ozone layer depletion, acidification, smog and loss of biodiversity
- The realisation that these problems have catastrophic impacts on natural ecosystems and on the life support systems of the planet
- The realisation that these problems have significant economic consequences through insurance losses, larger insurance premiums, “green taxation”, punitive fines and loss of customers as a result of rising "green" awareness
- The realisation that long term economic growth in the traditional year-on-year growth of GDP actually damages the economy through its negative consequence (air pollution, defensive expenditures)
- The realisation that the sum total of these negatives actually reduces quality of life especially through damage to health. The UK government Department of Health published a report in January 1998 showing that 20000 people die each year in the UK from the effects of traffic-related air pollution. Quality of life in cities has declined considerably in the last 30 years measured in opinion surveys covering safety, security, stress and conditions for children and the elderly.

There is perhaps one reason which transcends and embraces all the other reasons quoted above. We have now reached a point in societal development where it is impossible to hide from these problems. In the 19th century wealthy people could escape disease and pollution by separating work and residential locations, living upwind of our cities and retreating to country estates. The late 20th century has removed all these escape/avoidance strategies. Ozone pollution is higher in rural areas than in urban, diseases such as leukaemia have a preference for richer people, pollution in cars is higher than pollution on the side of the street (regardless of model, technology or price), congestion affects everyone and general health problems such as allergies, asthma, skin diseases and psychological problems do not spare the wealthy. We live in an age of the “boomerang“ effect where our profligate use of energy, wasteful use of resources and unintelligent approach to waste and pollution has an unerring tendency to return and exact its damaging toll on life, nature and health

Joined-up thinking

The UK government has predicted that there is a "need" for 4.4 million new homes by the year 2016. The prediction is based on past trends in the growth of new households and the fact that more and more of us will divorce and/or live alone. This has led to a frantic bout of activity by construction companies and by local planning authorities to identify sites and plan for the delivery of new homes. The discussion has polarised around the battle to protect green belts, green land and to preserve the countryside but has not yet focused on the wider implications of simply adding more and more to the housing total without first considering all the alternatives. Building a proportion (yet to be determined) of the 4.4 million new homes on green land is an environmental disaster and will add to all the negatives listed in the introduction to this paper. The bigger failure, however, is the failure to grasp the opportunities to plan in a flexible, intelligent manner to meet this demand by a variety of strategies that conserve resources, reduce energy and transport use and protect the countryside and green areas as an inevitable consequence of intelligent joined-up thinking.

- There are a number of stages in this process and these can be generalised to other debates in construction (e.g. roads and dams) and beyond construction to other sectors of the economy:

- Is the forecast accurate? How sensitive is it to variation in those factors that bring about this kind of demand? Would more support for families with-children reduce divorce? Would social policies that rescue people from poverty reduce the fragmentation of groups?

- If the numbers are accurate what kind of housing can be designed to cope with the demands of those who will be living alone. House builders want to build traditional 3-4 bedroom, semi-detached houses with garages on greenfield sites. Is this the kind of housing that will meet the forecast demand?

- How much spare capacity is there in the existing housing stock? How many empty units? how long have they been empty? Why? What can be done to bring them back into use?

- How-much commercial/industrial/office space is empty? How much of this space. can be recycled for residential purposes? Specifically how much empty space is available in every UK town centre above shops, banks, building societies, fast food outlets etc.? What can be done to bring these back into use?

- What kind of financial framework (taxes on greenfield sites, tax rebates on using former industrial sites, increased taxes on new raw materials and tax breaks on re-used materials) would produce a more intelligent use of resources?

- How much waste land, derelict land, former industrial land is available in the UK and how many units could be built on that land with what kind of provision for green space, woodland and recreational facilities as part of a housing programme on recycled land?

- How much land is occupied by car parks? How much of this could be released for housing development with more effort in the area of sustainable transport (walking.

cycling, buses, trains and trams). An element of joined-up thinking here has the potential to solve both housing and urban transport problems, particularly congestion and the health of urban dwellers

- How many more residential units can be built in a car-free residential area than in a car-rich residential area (with due attention to generous provision of green space in both).

It should be clear from these (far from exhaustive) steps in a logical process of policy making that there are a large number of alternative futures. The one we are likely to be stuck with is quite simply the one that is least imaginative and most severely constrained by entirely artificial, compartmentalised thinking. Even worse the most likely outcome, the "predict and provide" solution is most costly to society as a whole. New roads, new schools, new infrastructure generally will have to be built to serve these new areas whilst existing infrastructure elsewhere will be underutilised or abandoned at a loss to the taxpayer. The transformation of urban and regional space into a low density car dependent state will add to traffic congestion and pollution and illness thus emphasising once more the negatives that are so characteristic of our late 20th century resource profligacy. The relatively affluent occupants of these new houses in former greenfield situations will be remote from the facilities they wish to access, will spend large amounts of time inside their cars "enjoying" a personal chemical cocktail with lung damaging and carcinogenic properties and will be suck in traffic jams. Such is progress.

A way forward

The construction industry is a very important industry. It manufactures the built environment and it puts in place a physical stock of facilities and infrastructure that determines our degree of freedom and flexibility for anything up to 100 years after construction. This puts it in a very different league to the producer of photocopying paper, washing machines or cars. This importance is matched with responsibilities which are shared by all sections of society but have a special relevance to construction: These responsibilities can be summarised under a number of headings:

- The need to engage in and with the wider implications of commercial activity (joined-up thinking) e.g. Natural Step

- The need to adopt strong ethical and human rights policies (e.g. Reebok)

- The need to adopt high environmental standards throughout the business (e.g. ASG, Sweden)

- The need to adopt strong environmental management systems (EMS) through an appropriate standard (e.g. ISO 14001 or EMAS, the European Eco-Management and Audit Scheme)

- The need to be fully part of the region/city/locality in terms of devising and implementing Local Agenda 21 strategies and solutions

- The need to put into practice ees-design principles (e.g. Eco-Logica's study of environmentally responsible design for Scottish Homes, Eco-Logica, 1995)

- The need to plan for the maximum possible waste, energy and transport minimisation. Is enough being done to re-use demolition materials and reduce the use of sand, gravel, aggregates, cement, concrete and steel? Is enough being done to get freight out of lorries and onto trains, waterways?

Conclusion

No one expects the construction industry to abandon a profits driven, commercial perspective. The intelligent enterprise will be aware of the need to seek out new market opportunities, reduce costs, innovate and improve its competitive position. **This is exactly what an environmental perspective in business will deliver.** Environment.4 standards drive a continuous process of improvement in quality and identify opportunities and alternatives for doing things in different ways and in ways that will increase market share and increase profitability. An environmental concern leads to higher standards with associated higher value (price) products and more opportunities to build in (literally) added value. Added value means more services or products added to the basic product in a way that makes more use of the standard inputs of time, energy and overheads into construction projects. A house built to a high environmental standard can be sold at a higher prices and offers more opportunities for the construction company to add products and services that can be charged for.

These ideas have been developed in the context of freight transport (European Commission, 1998). The Commission has shown that there are many more opportunities in freight transport than are traditionally exploited by manufacturing or distribution companies. Many of these opportunities e.g. multi-modal transport and railways have been promoted by environmental arguments with relatively little success but are now being employed by commercial enterprises because they reduce journey times, they are cheaper or they allow expensive resources (e.g. lorries) to be better utilised. The conjunction of commercial imperatives and environmental imperatives provides a powerful metaphor for a completely new approach in the construction industry.

Collaborative performance-based purchasing for sustainable innovation

EL Westling
Promandat AB, Stockholm, Sweden.

Abstract
After an overview of current problems, an orientation is given about different mechanisms for innovation - R&D supply-oriented and demand market-pull efforts. Co-operative and technology procurement may contribute to substantial improvements with higher efficiency/productivity and cost/price reductions.

Experiences from finalised and ongoing collaborative purchasing projects in the construction and energy fields are analysed. In many energy projects the energy use has been reduced by 30-50% through the collaborative efforts by a group of future-oriented housing owners/buyers in Sweden. Similar increases in performance are also shown in the USA and France, using the combined purchasing power of buyers.

This stresses the importance of increasing the role of the owners as buyers in the construction sector. For more promotion of sustainable and environmentally-adapted solutions performance orientation will be very important. As established at the CERF 1996 Symposium, more international collaboration is crucial for formulation of requirements, testing procedures and contract rules, especially concerning long-term responsibility and warranties. The public procurement rules should promote both competition and innovation. The operating costs for facilities should play a larger role through LCC-evaluation of tenders.

As a prestudy, this paper could form a background for further international activities within CIB-CERF programmes and in Swedish programmes for a more efficient construction process.

1 Introduction

1.1 Possibilities

New challenges will meet all actors in the construction sector in the new millenium. Less pollution and resource consuming solutions will be asked for. Developers and suppliers will have to meet the increased awareness with more efficient solutions, which are also less energy-consuming and detrimental to the environment.

The possibilities of accelerating the introduction of more efficient solutions have been experienced in some fields. Reduction of energy use by half, reduction of total costs almost by half and/or speeding-up both the development process and the realisation of individual projects are results achieved by using *co-operative or technology procurement*. With this market-demand process major buyers and users articulate their needs in functional terms, aggregate their purchasing power, and accelerate the innovation and diffusion process. Through parallel work and early involvement of leading buyers and users, the risks are reduced for manufacturers

1.2 General problems in the construction sector

Many low-efficient, existing technical solutions, consuming large resources of energy, cost and time, are the results of a rather fragmented process, split up in phases and branches. It is also dispersed in geographical space. Manufacturers or contractors seldom know the total cost or energy use, and they very seldom meet the end users - being facility managers, maintenance personnel or consumers. Real needs are not articulated in performance terms.

The problematic general situation in the construction sector and future changes in the construction process required for accelerated, yet reliable innovation, have been treated in the Atkins reports on Europe [l].

1.3 Project Earth and operating costs

The impact of energy production and CO, emission on the possibilities of a sustainable situation in the world and the risks of a climate change has come into focus more during recent years. The part of the total operating costs which relate to energy, heating, ventilation and cooling has increased.

The right choice of more energy-efficient components with consideration of life-time costs will be crucial for the total project economy and also for the environment.

The International Energy Agency, IEA, with twenty-five important industrial countries as members has set up a special programme in order to facilitate the development and diffusion of more energy-efficient solutions [2]. The energy sector will be an important area for different policy actions. The recent trends of individualism and privatization in the energy sector will *reduce Government interventions with traditional measures.* Reduction of the use of pure grants and subsidies for energy-efficiency enhancing actions places serious constraints on the application to meet the goals of the Climate Convention and other energy and environment objectives [3]. Procurement methods that stress the long-term impact with the operating costs and open up for efficient new solutions would give all involved organisations competitive advantages.

2 Theories and definitions

2.1 Innovation instruments

Over the years, researchers have consistently debated which *instruments* are most effective in producing *innovations.* (In this context, it is important to note the difference between *inventions* and *innovations,* meaning new products, systems and processes which have left the laboratory and been introduced onto the market.) Some researchers have emphasised the supply side (technology push), others the demand side (market pull). The conclusion drawn in recent times is that initiatives are important on *both* sides, but that most innovations - some researchers say 75 per cent or more - have probably materialised as the result of steps taken on the demand side. Several researchers are agreed that apart from demand-side initiatives, efficient organisation and communication are also important [4 and 5]. Technology procurement is a method of working on the demand side [6].

The importance of involving the *customers* or users at an early stage, had previously emerged in studies from SAPPHO [7] and Rothwell [8], as well as by von Hippel at **MIT,** who has also emphasised the importance of lead users [9].

In many areas, the market is out of balance. There are many buyers, but they are not united, They may have valuable ideas but have difficulties imagining new products. Sellers and manufacturers are not well-informed about what their customers really want.

Interaction between users and producers and organisation of the market have been stressed by Lundvall [5 and 10] and the importance of a "central coordinating agency" by Teubal [11].

2.2 Definitions

Technology procurement may be characterised as an entire acquisition process aimed at directly stimulating innovation. It is not exclusively associated with any particular form of contract though it is closest to design/build contracting with performance requirements [12].

Collaborative purchasing (or co-operative procurement) may include both

- technology procurement (of something not yet existing on the market), and
- acquisition of existing products/systems (for instance among the 25 per cent most energy-efficient ones)

The most influential buyer or a number of *buyers* in combined efforts formulate the requirements and evaluate the products. The market transformation is further influenced by support activities (rebates, information, labelling, awards, etc.).

In some cases, the buyers represent only public organisations. In others, they may include private companies, individuals, or combinations of public and private organisations [13].

Lundvall [14] has also pointed out the importance of the *government in two different roles:* one as the traditional, large, *long-term buyer,* (for the defence establishment, infrastructure, etc.), and the other as an *intermediator, facilitating the building-up of networks and the creation of nodes, or joint organisations, for procurement* (similar to the Consortium for Energy Efficiency and the State Collaboratives in the United States, or the organisations HLM in France and HBV in Sweden, see further below).

3 Experiences - early and lately

3.1 Historical examples

Competitions have often inspired significant innovations. There are some well-known historical competitions and challenges, in which performance criteria were established, such as the solution of the Longitude Problem and the chronometer in the 18th century, and the technology procurement of railway locomotives in England in 1829.

Thus it was shown early on that a competitive element and performance criteria inspired progress by opening the way for innovative ideas.

3.2 Early projects in Sweden

Technology procurement has been used by the Swedish State Railways, SJ, from developing one of the most extensive railway electrification scheme of its time in the early 1900s, to the development of Asea Brown Boveri's X 2000 high-speed train in the 1980s. Performance requirements and strong buyers have also inspired development in energy-supply and telephone projects.

3.3 Construction and energy end-use projects

In some construction and energy areas, it has lately been possible to reduce the use of resources or increase the efficiency by 30-50 per cent in a relatively short time by using performance criteria, formulated by an influential group of buyers. In all the cases, the formation of buyer groups, consisting of leading housing companies with different owners, has been one important element. Special efforts are needed in the fragmented construction sector to get buyers to collaborate.

In some cases (e.g. lifts and bathrooms for existing buildings and energy projects) it has proved important to build up new networks across trade boundaries and establish cooperation between several large buyers. Table 1 illustrates the results from some technology procurement projects

Project area	Result	Energy reduction
Refrigerator/Freezer	From 1.2 kWh/litre comparable volume per year to 0.8	by 33%
Clothes washers & dryers for laundry rooms	From 2.6 kWh/kg of laundry to 1.2	by 50%
Ventilation. Replacement of fans in residential area	From 750 kWh/apartment and year to 380	by 50%
Heat pumps	Two different suppliers chosen for further development & deliveries	by 30 %

Table 1. Results obtained from some technology procurement projects in the energy field in Sweden. [2]

3.4 International examples

Similar methods have been used internationally, e.g. by the French organisation HLM, the Association of Municipal Housing Companies, in developing control systems for apartment houses, "Domotique", a form of intelligent buildings [15], and in the United States, a "Golden Carrot" programme was first used for energy efficient refrigerators (SERP) with 30-35 per cent energy reduction. It is now being followed by the Consortium for Energy Efficiency, CEE (with more than 25 utilities and other organisations all over the USA as members), in a number of fields, such as ventilating and cooling systems.

4 Specific environmental performance criteria

In many of the projects mentioned above - where a more efficient use of energy has been the main goal - there has been a combination with environmental requirements, see Table 2.

Project area	**Performance criteria examples**	**Relative weight in evaluation of tenders**
Refrigerators/freezers, NUTEK, Sweden, 1990	- Energy kWh/litre volume and year. Mandatory/ Desired: 1.0 and 0.8, resp - Removal of CFC - Environment description - Labelling	Quantitative in each part, energy most important. Qualitative between parts (+, 0, -)
Super Efficient Refrigera-tors, "The Golden Carrot", USA 1992	- Energy - CFC replaced by HCFC - Dissemin. of new model	Most important 3 points of 120
Clothes washers, NUTEK, Sweden, 1992-1995	- Energy kWh/kg clothes in standardised washes, different loads and temps. - Use of water - Noise Mandatory/Desired levels	Quantitative in each part, energy most important Qualitative between parts (+, 0, -) Pilot environment assessment
Ventilation, refurbishing in existing multi-family houses, NUTEK, Sweden 1997-1998	Mandatory/Desired levels - Minimum air flow - Noise - Maximum energy use etc	Qualitative and full-size prototype installation in steps, testing
Low-cost housing for the Governm. Delegation for Construction Costs, Sweden 1997	Energy use & environment in appr 20 different criteria Mandatory/Desired	20% weight factor totally for resources (energy) and environmental impact. 4 pilots for testing.

Table 2 Energy and Environment Requirements

Apart from the formulation of energy criteria (maximum kWh per year and comparable volume), the *refrigerators/freezers* project in Sweden also had the outspoken goal to reduce the use of CFCs. Other requirements specified included an environmental impact description and the readiness to show a label to facilitate the dissemination. Similar combinations of requirements for energy and environment have been used in some other projects as shown in Table 2 above.

5 Formation of buyer groups in areas with large fragmentation

As already mentioned, it is very important, especially in the construction field, to try to create a group of property owners who can act as buyers. They should be *future-oriented and be regarded as leading in their field,* (some of them may be so-called *anchor buyers).* It is essential to clearly show that they will be good channels to further markets - besides the first prototype projects. Through the buyer groups and the attention received for a project with large society support sufficient interest will be created among suppliers and contractors.

Many times, the creation of buyer groups can take a very long time. If there is not already a well-established network of people, working together in a trustful collaboration, such a network has to be built up. The buyers have to take part in a common engagement, consisting of clarification of problems, formulation of goals and specification of challenging performance criteria.

Buyers can be identified at several levels and in many areas of the construction process - from property owners, through design/build, general or main contractors, to subcontractors and suppliers of systems, components and building material.

The Swedish organisation HBV with publicly-owned housing companies as members, HSB, which is one of Sweden's major national organisations for housing cooperatives, and purchasing organisations for private property owners, e.g. in Stockholm, are examples of organisations involved in Swedish buyer groups. They are already important for the stimulation of innovative energy solutions.

In the programme set up by the *International Energy Agency, IEA,* mentioned above, a special Market Acceptance Process has been developed, see Figure 1, and buyer groups are being established for different projects.

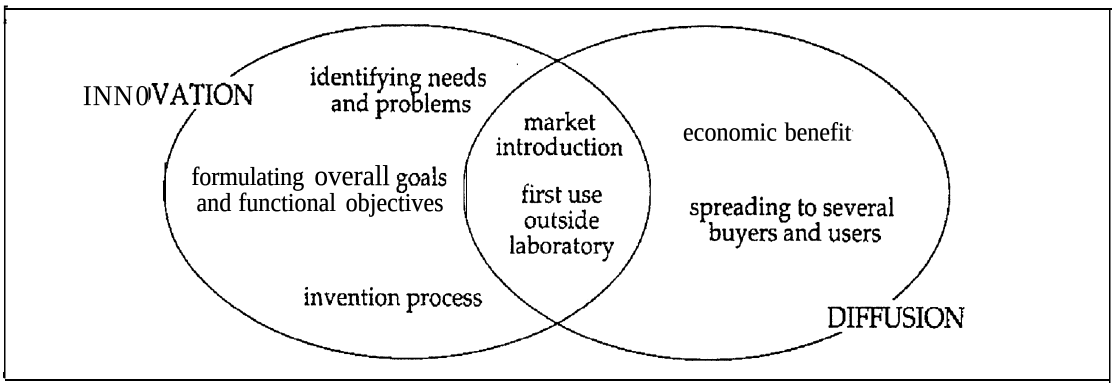

Figure 1 The Market Acceptance Process involves both innovation and diffusion of new technologies and applications.

One of the IEA projects is in the *"wet appliances"* area with a considerably more efficient, Class A type, *heat-pump dryer*. The Netherlands has the project management role. The first appliances will be delivered in the Spring of 1998 in Germany and The Netherlands. Preparatory work is also going on for a *more efficient incandescent lamp* with the United Kingdom as project-managing country, *copiers* (United States) and *energy-efficient motors* (Finland). Other planned areas include Active Solar Procurement.

Different State collaboratives, mainly for more energy-efficient solutions, have been established in the North East and North West of the United States. A number of States are working together, showing joint efforts, and thus creating a larger impact on the market.

We can see other examples now coming up, like "Green" Groups or "ECO" groups, which will work jointly, for instance in the United Kingdom, Germany and the Netherlands.

6 Lessons learned and problems for the future

We know that this working method is rather new with a lot of problems.

1. In many areas, there are no generally accepted *principles for formulating the requirements or for testing.* In some areas it has been essential to develop rules or to accelerate work, for example for refrigerators/freezers, clothes washers and ovens.
2. It will be even more difficult when you want to combine and weigh the different requirements for capital costs, yearly costs, use of limited resources and emissions.
3. The importance of internationally *recognisedperfirmance criteria* has been pointed out at the CERF Symposium in February 1996 in Washington D.C. Such criteria are essential in order to accelarate the development and diffusion of more environmentally-adapted solutions. This work will take a long time.
4. It is essential to build up buyer groups. It takes time to build up trust between organisations that have earlier seen themselves as competitors. It may sometimes be better to *build on already existing networks,* or groups of people, and add additional organisations, buyers and specialists to these groups.
5. It is true that the rules for public procurement, e.g. the European Union Public Procurement Directives and the Government Procurement Agreement of the World Trade Organisation, WTO, are positive to the technology procurement concentration on performance criteria. However, the rules have to be further looked into, so that they can stimulate further innovation and more efficient solutions.

   The Directives stress quite clearly that the request for proposals must include all criteria - preferably also in order of priority - which will be used in the evaluation of the tenders received to establish the most advantageous. It is however not required to state the exact weighting or priority.
6. A combination of different mechanisms for supporting innovation is very important, not only the purchasing or procurement, but also using information activities like labelling, minimum or maximum standards, etc.

Understandings of Environmentally Conscious Procurement Arrangements in Culturally Diverse Circumstances

M. A. Hall and D. M. Jaggar
Construction Procurement Research Unit, School of the Built Environment, Liverpool John Moores University, UK

Abstract
The construction industry, in common with most others, is becoming increasingly globalised. This has led to the emergence of Architectural, Engineering and Construction (AEC) Enterprises for whom international activities are no longer peripheral, but central to their operations.

In many developed regions of the world, environmental considerations are being seen as increasingly important. This is leading to the application of advanced materials and construction techniques for the construction of the built environment in those regions. Consequently, AEC enterprises have been required to incorporate environmental features into their procurement arrangements to account for increased legislation and to satisfy clients for whom the environment has taken a greater priority.

Where these companies are active globally, they have an ethical, and often a legal, imperative to transfer management and technical expertise to the host country, where that is appropriate. Increasingly, this will include their knowledge and understanding of environmentally sound procurement practices.

However, an obstacle to achieving this is the differences in culture they will encounter when working internationally. Cultural differences can lead to especially pronounced differences in the appreciation of man and his relationship to his environment. This, coupled with different understandings of the nature of procurement, together with differing aspirations and priorities, will present international AEC enterprises from the developed world with major challenges in transferring an environmentally sound approaches to the design and construction of the built environment to host nations.

This challenge can be eased if those enterprises improve their understanding of cultural differences and employ cultural management techniques where they encounter multicultural conditions.
Keywords: Cultural Diversity, Environmental Considerations, International Procurement Arrangements

1 Introduction

As we approach the end of the millennium, two key trends within the construction industry are taking on more importance than ever before. Firstly, the industry is becoming increasingly globalised. While there has been an international construction industry for more than a century [1], an ongoing, political and information led, globalisation process, coupled with changes in patterns of demand for construction activity around the world [2] & [3], is creating an international construction system unlike anything seen before [4].

The second trend is an increasing awareness of the environmental impact of construction activities. It has been estimated that, in the UK, construction, from inception through to end use ("cradle-to-grave") accounts for approximately 50% of national energy use [5]. The Rio Summit in 1992, together with the recent Kyoto Summit, have focused on the need to reduce the impact of man's activities on the environment. As the built environment accounts for such a large proportion of energy consumption, a host of measures are being developed, particularly in developed regions of the world, in order to reduce the environmental impact of construction.

Architectural, engineering and construction (AEC) enterprises operating internationally have an ethical duty to transfer their knowledge and technologies to host countries. As they incorporate more environmental considerations within their procurement procedures, these too must be transferred to countries with procurement practices that are less advanced from an environmental perspective.

One of the main barriers to the successful transfer of technology, is cultural distance. This paper seeks to explore the impact cultural differences may have on relative interpretation of environmentally sound procurement arrangements and the consequences this could have for those companies seeking to transfer knowledge, practices and technologies of this nature.

The paper is not intended to present empirical data. Rather, the aim is to investigate the issues of concern from a theoretical perspective. Thus, the paper draws on existing theory and data in order to advance propositions which can be developed through future research.

2 An increasingly global construction industry

Many anecdotal sources point to the increasingly global nature of the construction industry. However, perhaps the most compelling evidence for this is the increasingly complex weave of cross border holdings within the European construction industry [6]; a phenomenon that is increasingly extending beyond Europe's borders [7]. Bon's [S] ongoing research reinforces this view.

A further demonstration of the process of globalisation within the construction industry is provided by research conducted by the Construction Industry Institute (CII) and American Society of Civil Engineers (ASCE) in the US [9], which notes that chief executives of North American architectural, engineering and construction (AEC) firms identify further exploitation of the global market as a major area of future growth and expansion in what is seen as an increasingly stagnant and saturated domestic market.

3 The environment and the construction industry

The Rio Summit in 1992 and, recently, the Kyoto Summit, have highlighted worldwide concern for environmental issues. The very nature of construction activities mean they have an implicit and significant impact on the regional and global environment [10].

Concern among both clients and governments has resulted in increased demand for procurement measures which act to reduce the impact construction activity has on the environment. Consequently, construction professionals need to be a position to make procurement decisions based on environmental, as well as technical and financial criteria [11]. Ofori [12] suggests that there is a strong case for considering the environment to be an additional project constraint.

The effects of construction on the environment can be considered in three broad areas: global issues; local issues; and internal issues [13]. As they are discussed below, it should be borne in mind that the issues are considered from a specific cultural paradigm. In other cultures and societies, differnet environmental issues may be considered more important or relevant. Furthermore, this is not intended to be either a prescriptive or definitive catalogue of environmental issues relating to construction.

The construction industry is a major contributor to global environmental damage for, a number of reasons. The industry is a high user of fossil fuels. It has been estimated that, in the UK, the construction industry accounts for up to 50% of the nations energy use both in the production, transportation and fabrication of construction materials as well as in the construction and life time use of the building itself [14]. Furthermore, large quantities of CFCs, and other harmful materials, are used in refrigerants, insulation and air conditioning plant and equipment. Additionally, the construction industry uses great quantities of raw materials, obtained by extraction, mining and deforestation. Materials obtained by these means exert pressure on regional environments due to the possibility of flooding, droughts and soil erosion.

Construction professionals need to consider the use of alternative fuels, such as natural gas, and specification of CFC free insulating materials. They should also develop alternative design solutions that do not automatically call for full air conditioning installation. They should consider implementing energy efficiency measures, including optimising daylighting, making use of natural ventilation and passive heating and cooling. Finally, greater use should be made of recycled and renewable materials, while construction waste should be more carefully managed.

Naturally, construction activities also effect the local environment. Air and water pollution are caused by dependence on factors such as road transport, inefficiently designed buildings, high fuel consumption, pollutants from materials manufacture, wood preservatives and dewatering of sites.

Consequently, construction professionals must be more aware of the possible impact of their activities on the local or external environment. In particular, contaminated land should be carefully investigated, with a sound proposal for the disposal, encapsulation or treatment of any contaminants found.

Internal building environments have a significant impact on the quality of our lives [15]. Hazardous and toxic materials in the structure and fabric of the building can effect the well-being of both construction workers and building occupants and can lead to conditions such as sick building syndrome.

Sensitive procurement procedures, such as the use of atria, provision of indoor plants, use of daylight and task lighting and specification of materials that emit lower levels of chemicals, can all help to create acceptable and healthy indoor environments.

4 Technology transfer and environmental procurement considerations

Where AEC organisations choose to operate internationally, they have an ethical, and often legal, imperative to transfer technical know-how to the host country. They also use technology transfer for competitive advantage [16]

The transfer of technology, in all its manifestations, has been well researched in many industries. Technology can be transferred both between industries (the car industry to the construction industry being a common example) and within an industry but between countries (international technology transfer). It is with the latter process that this paper concerns itself. There are also instances of technology being transferred both between industries and internationally, such as the British construction industry adopting production techniques developed in the Japanese car industry.

Barrett [17] describes technology within the construction industry as a continuum, ranging from conceptual 'technologies' such as "open systems" concepts of construction, through managerial 'technologies' such as the "design-build" procurement route, to physical technologies such as a specific concrete mix. This model has been used in. figure 1, with some factors associated with environmental procurement procedures ranged beneath.

CONCEPTUAL	MANAGERIAL	PHYSICAL
Producing a constructed environment that has a lower environmental impact	'Improved design approaches and techniques	
Environmental legislation which effects regulates the activities of the construction industry		Alternatives to/reduced provision of air conditioning
	Waste management procedures	Super insulating materials
'Cradle-to-Grave' analysis of building energy requirements		Improved specification .
		Use of recycled materials
	Use of 'lower energy-embodied' construction methods and materials	High efficiency heating, lighting and ventilation equipment

Figure 1: adapted [18]

Barrett concedes that the model is an over-simplification and the terms ranged below the model, together with their positioning, are open to debate. However, figure 1 is useful in that it serves as a framework for discussing the transfer of environmental procurement issues in relation to cultural differences.

5 The potential impact of cultural differences on technology transfer

Andrews [19] suggests that effective transfer occurs when technology is requested, transmitted, received, understood, applied, diffused widely and improved. A potential barrier to this is the effect of cultural differences. This view is supported by Hemais [20], who developed a model identifying the main dimensions for consideration of international technology transfer. One of the key aspects incorporated within that model is 'cultural distance'. The impact of culture on the transfer of technology within the construction industry, was explored in broad terms at a recent CIB Workshop [21].

In that workshop, Barrett [22] proposes a curvilinear relationship between the effect of cultural differences and the continuum of technologies model, used in figure 1. This proposal is illustrated in figure 2A below.

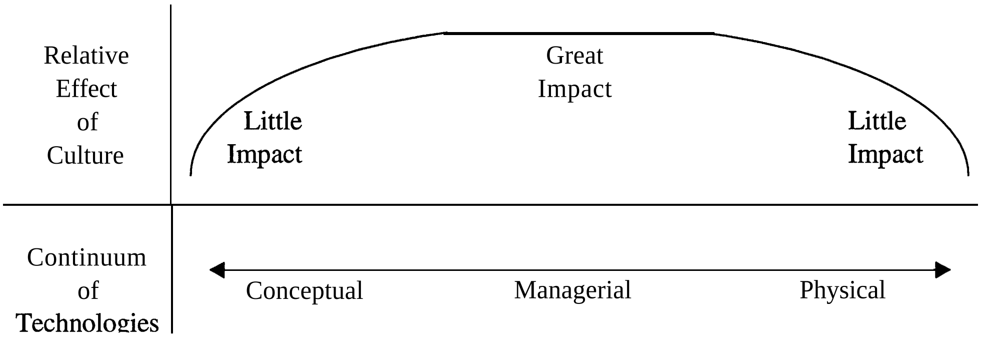

Figure 2A: Varying Impact of Cultural Differences [24]

This is considered to be a critical point, as it implies that culture has little influence on the ability of different societies to assimilate new concepts; that they are easily adopted by the recipients. If it is assumed that, for the managerial and physical stages of technology transfer to be successful, first the conceptual stage must be understood and be 'bought into' by the receiving party, then the conceptual stage is the most crucial. Seymour [23] makes this point when he says:

> " Developing and implementing new technolog[ies] require[s] that the familiar and everyday be looked at afresh and alternatives be imagined and turned into practice." (p. 3)

From a cultural viewpoint, if the managerial and physical features of a given technological concept are seen as 'practices' and 'explicit products or artefacts', then the conceptual aspect of that technology lies within the domain of the 'norms and values' that underlie those practices, products and artefacts [25] & [26].

Practices (the managerial and physical features of technology) are, in this sense, "observable reality" [27], while the underlying values:

> ". ..remain unconscious to those who hold them. Therefore, they cannot be discussed, nor directly observed by outsiders. They can only be inferred by the way people act under various circumstances." [28]

Thus, the value-system of a given society, wherein the concept of the technology will be understood and endorsed, and which is essential if the technology is to be implemented through managerial practices and physical products, is the point where cultures vary in their most fundamental ways. Therefore, at the conceptual stage of the model, the impact of cultural differences is really at its most pronounced and as the technology moves through managerial to physical manifestations of that technology, the impact of culture diminishes. Consequently, the following modification to the model is proposed.

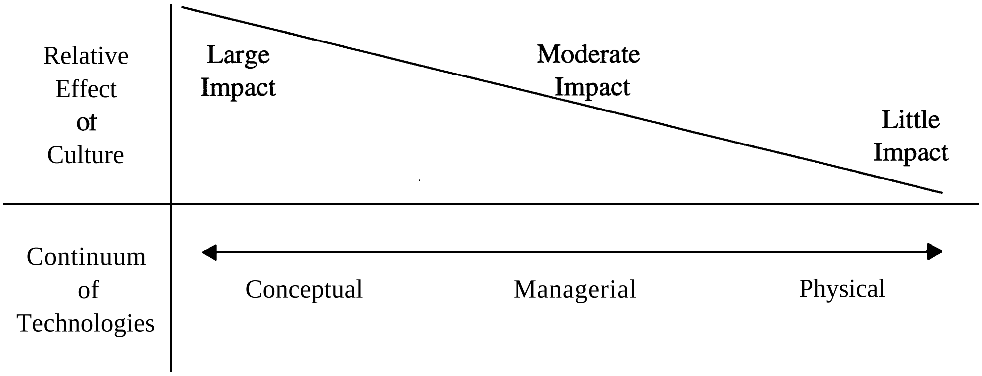

Figure 2B: An alternative view of the varying impact of cultural differences

6 The effect of cultural values have on environmental concern

If the principal cultural barrier to transferring environmental procurement technology lies at the conceptual level, and within the value-systems of differing cultures, then the chief difficulties in transferring that technology will be value based.

As part of his attempt to understand culture, Hofstede and Bond [29] established a series of five cultural dimensions. Two of these dimensions; 'collectivism/individualism' and 'long-termismkhort-termism' are of interest in this respect. This is because environmental issues, especially at the global level, are non-immediate phenomena effecting large populations. As the time difference between cause and effect leading to environmental impact is relatively long (e.g. not immediate), those cultures with a short temporal focus will be less inclined to implement measures reducing that impact than those cultures with a longer temporal focus. Similarly, as environmental impact effects many people, those with a more collectivist orientation will be more concerned in mitigating environmental impacts than those with a more individualist orientation.

Thus, the construction industry of a given society with high scores on both the collectivist and long-termism dimensions would have a higher propensity to incorporate environmental measures within their procurement arrangements than those with lower scores.

The picture is rounded out by another cultural dimension identified by Trompenaars [30] - the role cultures' assign to their natural environment. Trompenaars postulates two extremes (p. 125). On the one hand, there are those who "believe they can and should control nature by imposing their will upon it". Such people are "inner-directed". On the other hand, there are those who "believe that man is part of nature and must go along with its laws, directions and forces". These people are "outer-directed". In broad terms, the latter attempt to live in harmony with their environment while the former live in spite of their environment. Thus, it could be said that construction professionals that come from a culture that is more inner-directed would be less concerned about incorporating environmental measures within their procurement arrangements than those that come from a more outer-directed culture.

7 Conclusions

Undoubtedly, environmental issues will be firmly on the world agenda for the foreseeable future. But it is only now that nations have attained the political maturity to commit themselves to targets for improvement in their environmental impact. The construction industry will have a major role to play in achieving these targets and, with increasing globalisation of the industry, there is an excellent opportunity to share knowledge, expertise and skills for developing the built environment in a way that is less harmful to the natural environment. This knowledge, expertise and skill has, for the purposes of this paper, been considered as a specific group of technologies.

It is argued that, for technology to be successfully shared (or transferred), the recipient must, crucially, endorse the conceptual element of that technology. Culture is one (of many) potential barriers or hindrances to successful technology transfer and, it is contended, has greatest impact at the conceptual stage. Furthermore, the conceptual element of a technology is rooted in the value-system of a given culture.

Drawing on existing theory, it is proposed that, in broad terms, it is possible to determine the propensity for a given culture to incorporate environmental considerations within their procurement arrangements. This knowledge could help AEC companies (or other organisations) in deciding the best way to encourage the construction professionals of various cultures to adopt environmental criteria in construction procurement.

Barrett [31] notes that cross-cultural technology transfer may be more influenced by the difference in professional sub-cultures between, for example, architects and engineers, than by cultural differences at the 'national' level. A pilot study [32] lends some support for this view. However, where there is a wide cultural difference at the 'national' level, (between high-context and low-context cultures [33], for example), cultural differences at a 'national' level must be a (possibly additional) factor.

Finally, Lansley [34] warns that culture generally may be attributed too much importance in effecting technology transfer. While it is agreed that culture is only one of many factors effecting the success of technology transfer, Gyekye [35] notes that:

> "Like science, technology - which is the application of knowledge or discovery to practical use - is also a feature or product of culture. It develops in the cultural milieu of a people and its career or future is also determined by the characteristics of the culture."

Contract Provisions for Effective Dispute Resolution

R. Mark Entwistle B.Tech., LLB(Hons),FRICS, FCIOB, FCIArb., FFB.
Barrister (not practicing)

Director of the Academy of Construction Adjudicators
Executive Director of James R Knowles, Construction Contracts Consultants
Council Member of the Chartered Institute of Arbitrators

Abstract: The U.K. construction industry has extensive experience in the resolution of commercial disputes utilising a variety of processes, which range from the formality of litigation to the relative informality of mediation and negotiation. The procedures available have recently been extended by the introduction if legislation compelling construction contracts to make provision for adjudication to be available to the parties.

This development follows other recent initiatives which are designed to remove confrontation from the construction process and to encourage a more co-operative working environment. The U.K. experience, reflecting both advantages and pitfalls is instructive to other countries where construction disputes are commonplace.

Introduction

The very nature of the construction industry renders it susceptible, more than most industrial activities, to a high incidence of disputes being likely to arise. This scenario is seen throughout the developed World and has given rise to numerous, varied, approaches to dispute resolution.

Underpinning all attempts to systematise the resolution of disputes, in whatever constructional or legal culture the subject has been addressed, has been the recognition that two specific, and often themselves conflicting, demands need to be satisfied.

The first is the fact that the parties involved are commercial **-** probably in their nature and certainly in their outlook. This inevitably, to a greater or lesser extent, places a premium upon the parties preserving (or at least suffering containable damage to) their ongoing relationship.

The second demand is for the process to achieve a result which the parties either accept brings an end to their dispute or, alternatively, which is legally binding upon them. The root of this particular demand is the need, both commercially and legally, for some measure of finality to be achieved.

The steadily increasing burden of work put upon the Courts in many legal systems has made it imperative that effective measures be put in place to spread that workload onto lay practitioners. There is also a discernable movement in the United Kingdom towards decreasing the cost to the taxpayer of running the legal system, both in civil and criminal matters, and requiring parties to commercial contracts to pay for the majority of their dispute resolution, as is the case with “lay determinations”, will contribute substantially to that goal.

Further, where the parties themselves are required to bear, between them in some proportion, the costs of the tribunal, they are likely to have a greater interest in the efficiency of proceedings.

In recent years various developments have occurred in the U.K. with the objectives of expediting and simplifying the dispute resolution processes available to the construction industry, so that the position has been reached where a number of such processes may be selected by contracting parties.

The choices open to a disputant which may be available to achieve a settlement, are:

- negotiation or abandonment
- litigation
- arbitration
- ADR (Alternative Dispute Resolution)

1998 will see added to this list **adjudication** which has hitherto been utilised only in very restricted circumstances, but which is now to be made mandatory for inclusion in construction contracts.

Dispute Resolution in the U.K.

Assuming the dispute is not capable of resolution by consent and the claimant is not persuaded by commercial constraints to abandon the matter, then it has the right open to all citizens to litigate in the courts. Construction cases are generally heard by Official Referees, who have come to specialise in the area and, as a result of the high esteem in which they are held, many parties (or more particularly their lawyers) prefer to litigate their disputes.

Commercial people, however, have for centuries recognised the advantages of an alternative which is private and more flexible, and this has given rise to the widespread use of arbitration. However, the popularity of arbitration in construction appears to be waning and, although international disputes are still commonly referred to arbitration in London, the number of domestic referrals (judged by the number of nominations of arbitrators by professional Institutions) has dramatically diminished in recent years.

More recently, prompted by initiatives in the USA, Alternative means of Dispute Resolution have become more popular, including conciliation and mediation. No form of ADR leads to a binding resolution of a dispute unless both parties agree to any compromise suggested. Where there is such agreement, then action can be taken for any breach of the terms of the compromise reached.

The difficulties experienced by the industry in this regard formed a significant part of the considerations by Sir Michael Latham which led to his report “Constructing The Team” in 1994.

The report includes amongst its recommendations that *"a system of adjudication should be introduced within all the Standard Forms of Contract"* with the express exception of contracts which already contain *"comparable arrangements for mediation or conciliation".* It was also recommended that the proposal for adjudication should be underpinned by legislation.

Latham made three principal stipulations, viz:-

(i) there should be no restrictions on the issues capable of being referred to adjudication;

(ii) the adjudicator's award should be implemented immediately;

(iii) appeals were to be permitted but generally only after implementation of the decision and only after practical completion. Latham did recognise there might be exceptional issues for the courts to decide which could delay implementation.

Adjudication

The use of adjudication in construction contracts in the U.K. has been severely restricted and did not exist at all in standard form contracts prior to 1976. Indeed, the present position is that adjudication is only available if agreed to by both contracting parties (normally by means of a set of adjudication clauses in the construction contract).Nowadays, resolution procedures by a third party appointed under the contract as an adjudicator with powers in respect of defined disputes exist in a number of standard forms of contract and subcontract.

There is no legal definition of the term adjudication although adjudicators appointed by the Lord Chancellor sit in various capacities, for example as Immigration Adjudicator to hear appeals from inferior tribunals.

The Shorter Oxford English Dictionary defines adjudication as "*To try and determine judicially ".* The term *"Judicially"* connotes acting fairly in arriving at a decision. However, it is important to keep in mind that adjudication is not arbitration, and is therefore not subject to the Arbitration Acts unless any of its provisions are incorporated in the adjudication procedures. Some might therefore use the hybrid expression 'quasi-judicial', suggesting that the adjudicator whilst exercising a judicial function has not been appointed an arbitrator under the Arbitration Acts.

The very nature of adjudication is different from the more formal processes of litigation or arbitration, in that the expectation is that a result will be declared by the adjudicator in a relatively short timescale. This should encourage parties in its use, even for relatively minor disputes, since costs incurred are not likely to be great. Given the probable timescales involved - days or weeks rather than months - the adjudicator is expected to give a Decision without the benefit of the sort of comprehensive evidence and legal submissions which an arbitrator or judge could expect. There is, as a result, understandable concern over the abilities of prospective adjudicators and a number of reputable professional Institutions have established rigourous training courses to meet those concerns.

The House Grants, Construction and Regeneration Act 1996

The Act received the Royal Assent on 15th July 1996. Part II of the Act, that is Sections 104 to 117, deal with construction and can be referred to as **"The Construction Act".** That Part deals only with two matters, both of which address issues raised by the Latham Report. These issues are:

- payment provisions, and
- dispute resolution by adjudication.

The "Construction Act" will not come into force until the Secretary of State for the Environment, Transport and the Regions, issues the necessary Statutory Instrument, which is expected to bring the Act into force around April 1998. Sections 104 to 108 deal with the subject of adjudication and give every party to a construction contract the right to refer any dispute arising under the contract for adjudication complying with the statutory code.

The application of the Act is subjected to several restrictions, a number of which may operate to the disadvantage of the industry generally; although it should be kept in mind that parties to construction contracts may chose to allow for adjudication in their contracts, even though not strictly compelled to.

- The Act is not retrospective. It applies only to contracts entered into after the commencement of the Act (section 104(6)(a)), whenever that is decided by the Secretary of State.

- The Act applies to England, Scotland and Wales but not Northern Ireland (section 104 (6)(b)).

- The limited definitions of *"a construction contract"* and *"construction operations"* (sections 104 and 105) means that the Act applies only in respect of work of a type defined within it. Whilst the definitions include all work which would generally be expected to fall within the ambit of contractors and subcontractors, there are several surprising exclusions. The Act also extends beyond the tasks of constructing to include application to the appointments of designers and advisors.

- The Act does not apply to contracts with residential occupiers (section 106), although subcontracts placed in connection with work which is ultimately for a residential occupier must comply with the Act.

- The Act only applies where the construction contract is in writing (section 107) but the definition given to a "contract in writing" is extremely broad and is likely, in practice, to exclude only the contract in which nothing at all is ever written.

- The adjudication procedure is a right operative at the behest of either party and is otherwise not mandatory.

Adjudication provisions (section 108)

- This section starts off with what is, at first sight, a very simple and straightforward statement:

> *"Subject to the aforementioned restrictions any party to a construction contract has the right to refer a dispute under the contract for adjudication under a procedure complying with this section."*

This simple procedure is likely to have a number of teething problems and the following points should be noted:-

* adjudication is not obligatory but is available only if a party exercises the right to call for it;

- adjudication is limited to disputes *"arising under the contract"*

  what is a *"dispute"*? - an assertion by one party denied or rebutted by the other

  "under the contract" connotes a narrow meaning (compare, for example, *"arising out* of' which carries a wider implication), but the wording is wide enough to cover all disputes emanating directly from the contract though it does not cover misrepresentations inducing the contract and any action in tort;

If the procedures set out in the contract do not comply with section 108 then the government "Scheme for Construction Contracts" will apply. By this means parties whose contract does not provide for adjudication as demanded by the Act will have terms implied into that contract, effectively bringing about compliance.

On the assumption that the construction contract complies with section 108, the procedure when compared with other dispute resolution processes, reveals that:-

- the parties can consent, by way of particular construction contract provisions, that the adjudicator's Decision is final and binding;

- save where the parties do agree as above, the Decision of an adjudicator binds the parties unless and until that Decision is overturned by litigation, arbitration (if the parties have an arbitration agreement) or by subsequent agreement of the parties;

- the adjudicator is not acting as an arbitrator but making an expert determination;

- the adjudicator is to be given immunity from being sued save where having acted in *"bad faith"*;

- the adjudicator is obliged to follow the procedures set out in the contract and/or his/her terms of appointment;

- the adjudicator is not bound to give reasons unless obliged to by the particular procedures in the contract;

- the adjudicator can act inquisitorially, is seemingly not expected to carry out a judicial hearing and will normally never need to hear oral evidence.

Benefits and drawbacks of adjudication under the Act

Some of the perceived benefits are:

- a universal right for any party to a construction contract to have a dispute *“decided”* by an independent third party, promptly;

- once adjudicated it is thought the majority of decisions will be accepted leaving the parties free to proceed with their normal contractual obligations;

- the adjudicator’s Decision has to be implemented before a challenge by litigation/arbitration can be made;

- it should be a very quick and cheap process;

- it should promote a better atmosphere on contracts by minimising major confrontational situations;

- it can enable the adjudication to be accomplished with a relative minimum of expert and lawyer involvement.

The features which distinguish adjudication from other dispute resolution processes are the combination of speed of application with the binding effect of the adjudicator’s Decision. The particular benefits arising from the effective use of the process are that the parties should achieve an independent decision in a relatively short timescale (within 35 days of the Notice of Dispute under the Act), and this should enable the parties to preserve a co-operative working relationship.

The process of adjudication, as now to be statutarily imposed in the U.K., is not without potential drawbacks, however. Those suggested by certain commentators include

adjudication may not result in a fair Decision and could resemble “palm tree justice”;

- as ever, the large and wealthy parties can prepare more sophisticated submissions and/or are better able to challenge an adverse Decision in subsequent arbitration/litigation;

- it will lead to a proliferation of formalised disputes;

- there is a relative absence of persons presently able to properly fulfil the role of adjudicator. One of the objects of the Academy of Construction Adjudicators is to address the present shortage of trained adjudicators. By the end of 1997 almost 200 construction practitioners had successfully completed the Academy's training scheme.

- some disputes are not capable of proper adjudication;

- to implement a Decision which is subsequently overturned by arbitration/litigation could lead to bizarre results, for example where alleged non-conforming work had been taken down and that decision was subsequently overturned.

The appointment of adjudicators is also a cause for concern, particularly since the Act expects the appointee to be in place within 7 days of the Notice of Dispute being served by the referring party. The parties could name an adjudicator in their contract from the start, but a dispute might arise which was outside that individuals sphere of technical expertise. The alternative, which is expected to be most widely used in practise, is for the parties to select their adjudicator (or have one chosen for them by a nominating independent body) after the dispute has arisen. Either method of appointment is permissible under the Act.

None of these matters are considered likely to prove insurmountable, however, and can be overcome by considered drafting of other terms of the contract and by the parties themselves ensuring that the process works.

Summary

Although adjudication is not new to the U.K. construction industry, its use hitherto has been limited to restricted application in a number of specific standard form contracts. Even there the number of references of disputes to the selected adjudicator were few. Many approved adjudicators, even when named in contracts, have achieved much more than 1 reference per year.

The implementation of the "Construction Act", however, can be expected to cause a significant increase in the number of disputes referred to an adjudicator. That is not to say that the number of disputes is likely to rise; rather that adjudication will come to be seen by the parties to construction contracts as an extremely useful and practical mechanism for assisting them to achieve their objectives for the project - for uniting the parties rather than dividing them.

Critics of the Act and of the process of adjudication generally, who are largely drawn from the ranks of the legal profession and thus have a vested interest in defending the more formal methods of dispute resolution, claim that the process, for a variety of legal and practical reasons, will prove unworkable. That is not the view of the construction industry at large, who see adjudication as a means of retaining control of their disputes and the cost of their resolution.

Environmental Assessment of Buildings, Building Operations and Urban Areas

Alan Yates and Roger Baldwin
Centre for Sustainable Construction, BRE, Garston, Hertfordshire, UK

Abstract

Sustainable Development is one of todays key issues generating a wide range of concerns ad initiatives world-wide. If the maintenance of economic activity, growth and, therefore, quality of life for mankind are to be successfully balanced with a sustainable environment, measurement will be crucial.

Buildings account, directly or indirectly , for a large share of societies environmental impacts. Since 1990 BRE has been developing and operating environmental assessment methods and guidance aimed at minimising the impacts of buildings BREEAM is a consensus based environmental assessment method for buildings, embodied in an accreditation scheme. BRE's environmental management 'Toolkits', launched in 1995, provide a means of reviewing the impacts of an organisation and prioritising actions by measuring both financial and environmental burdens. Both have gained wide spread support and use in the UK and substantial interest internationally. A range of building types is being covered by BREEAM and this is increasing most recently through guidance for the Retail sector and a 'Toolkit' for schools.

Due to limitations of knowledge, consensus or practicable solutions there are significant areas that these tools have not been able to cover. This paper explores three of these issues and the work that BRE has carried out on them. It sets out the potential for developing practicable industry measures and guidance capable of being included in these tools.

Key words: Sustainability; Environment; Buildings; Assessment; Guidance; Management; BREEAM; Embodied CO_2; Visual impact; Weighting .

Environmental Assessment of Buildings, Building Operations and Urban Areas

Alan Yates and Roger Baldwin
Centre for Sustainable Construction, BRE

1. Introduction

The concept of sustainable development is gaining high profile political and media interest since it is increasingly being seen as one of the key issues for the global society. The protection of the environment, a central plank of sustainability, is generating a wide range of initiatives world-wide. At the Rio conference a process of international collaboration was initiated and despite many reservations the 1997 conference on greenhouse gas emissions at Kyoto moved this process forward.

Buildings are linked to a large number of environmental impacts. In the UK and other Western European countries, buildings account for about 50% of primary energy use (and hence CO_2 output), far outweighing the contribution of either transport or industry. Buildings are, however, vital to the continuing economic health of our societies. This link between environmental concerns and continued economic and social activities - exemplified in buildings issues - central to achieving sustainability. The balance between protection and development is not easy to and will be debated well into the future. But any solutions proposed will have little basis if impacts are not measured and analysed.

Since 1990, BRE has been operating and developing environmental assessment methods and guidance for a range of building types. The Building Research Establishment Environmental Assessment Method (BREEAM) is a consensus-based environmental assessment method, embodied in an accreditation scheme. This method has provided, for the first time, a simple and practicable assessment of the environmental impact of a building across a wide range of issues relating to the global, local and internal environments. It builds on marketplace incentives to achieve real and meaningful reductions in the environmental impacts resulting from buildings and their operation by providing and demonstrating direct benefits. It has gained widespread support and use in the UK and substantial interest internationally. BREEAM was initially developed for new office buildings [1] by BRE in collaboration with ECD Energy and Environmental Consultants and industry. There is now a portfolio of assessment methods covering existing Offices, industrial units, superstores and supermarkets and new homes [2][3][4][5]. Guidance for the retail sector is currently under preparation [6]. Previous papers presented by the authors and others set out the background and development of the scheme. In parallel, BRE has developed the Office and School Toolkits [7][8] which take the concept behind BREEAM into new management areas related to building and office. These provide simple environmental toolkits for building occupiers to allow them to assess both the environmental and cost impacts of their activities and so help managers to prioritise their future action plans to maximise improvements in both fields. Linking the environment with costs in this way gives a very powerful message to business that it is in their own interests to address environmental issues.

BREEAM has become widely accepted in the UK construction and property sectors as a representation of current best practice in environmental design and management. For some time, though, BRE has been aware of substantial gaps in the coverage of issues owing to a lack of knowledge, consensus or practicable solutions for building owners and designers. There is also the need to expand the scope of BREEAM into the wider realms of sustainable construction. It is probably not sensible or practicable to include major economic and social issues within a simple tool and at the same time preserve its user friendliness. However, there is a need both to continue to assess environmental issues and to extend the same basic approach to other sustainability criteria. This paper explores three issues that might be included and the potential for developing practicable, consensus-based measures capable of being included within tools such as BREEAM and the Toolkits.

2. Embodied energy and CO_2

The issue of the embodied energy in a building has become an issue both in research and practice. In reality the CO_2, SO,, NO_x etc. embodied in materials and components are more of a concern as energy content is a cost issue that the market place will tend to regulate through competition.

The *Green Guide to Specification* [9] is one source of guidance available to designers. It is a system of environmental profiling for building specifications in the UK commissioned one of the UK Government's largest property portfolios, Post Office Property Holdings. The publication is designed to be an easy-to-use reference document for busy professionals actively engaged in design and construction and is based upon an extensive collection of existing , mainly public domain, data. It provides A, B or C environmental ratings for 120 building products, components and materials in terms of embodied energy, emissions, consumption of resources, recycling issues and toxicity. Details of the Green Guide and its development were presented in a keynote paper at the CIB-TG8 conference on Buildings and the Environment in Paris in June 1997 [10]. Whilst its authors, Shiers and Howard, recognise the limitations of the data on which it is based, they are also clear about the advantages of a book with a simple rating system.

This publication was devised to provide a useful tool for designers working for the Post Office. There are, however, a number of limitations to its wider use. The specifications covered are limited to those most used by the Post Office and some significant elements are not included. Despite this, the Green Guide has been rapidly accepted by designers, especially for use at the early design stage, even though it was not marketed vigorously.

BRE is now collaborating with the Post Office in further developing the Guide. The new version will have a wider range of specifications and more refmed categories included in the assessment. These will ensure that sufficient options are included for a credible assessment to be made for many types of building. The revised guide may be incorporated into future revisions and versions of BREEAM although the basis on which credits would be assigned has yet to be determined. It is expected that the Guide will be updated every 3-5 years in concert with BREEAM revisions seeking always to use the best available data.

Simple guidance of this form is needed for use by designers at the early stages of a design process when key decisions are being made. It is complementary to the more complex Life Cycle Analysis (LCA) methodologies now being developed and to the use of the UK National Database of Construction Materials, Components and Buildings due to be published by BRE in December 1998.

Although the market has eagerly accepted the simple guidance offered in the Post Office publication, its authors have been keen to test it against other established methods. The only comparable method is that offered by the *Handbook of Sustainable Building* [1 1], which is based upon a methodology devised for the Dutch Government. The two books use similar design specifications and environmental parameters, and share a common purpose. In a comparative study by Thomas in 1997 [12] which compared ratings given for 2 1 building specifications and materials it was demonstrated that despite having been derived from different methodological backgrounds and data sets, the two methods provided similar rankings for similar materials and design specifications. Most significantly, the "Preference levels" in the Handbook show a strong correlation with the Green Guide overall A, B, C ratings in the advice offered, as shown in Table 1 below. This finding gives to designers.

The Green Guide Ratings:	Environmental Preference Ratings:			
Total Number of:	1	2	3	Not Recommended
A's	5	6	0	0
B's	0	2	1	1
C's	0	0	2	4

Table 1 Comparison of the *Green Guide to Specification* A, B, C ratings with the *Handbook of Sustainable Building* Environmental Preferences

3. Visual Impact of Buildings

A major impact of buildings and development on communities is the visual impact that they have. This has both a profound environmental and social impact. Much has been written on this subject but little attempt made to develop assessment methods despite its being one of the more contentious issues related to development. In 1995, BRE commissioned the University of Surrey, Department of Psychology, to carry out a survey of views and to test some of the current theories. The survey although small, included a representative sample of individuals from the major interest groups as follows:

- developers
- architects
- other design consultants
- planners
- the public

Each group was asked to comment on a set of visual criteria developed from published material on the subject and to express their willingness to address these issues.

As expected, there was substantial disagreement on the issues that should be included in any assessment and in the methods suggested for assessment. The most supportive groups were planners and the public followed by architects. Developers were the least keen to see visual impact addressed as an issue. They feared over-prescriptive recommendations from the process and tended to concentrate on issues relating to the context such as landscaping and signage rather than building details. However, all groups were generally positive to the concept of assessment provided that this non-prescriptive approach were followed.

A range of issues were generally agreed as being relevant. These can be categorised as:

- form and massing
- external materials
- context - urban / rural / townscape
- landscaping
- security
- internal / external visual links

Less consistent was the means of assessing these. Few can be easily quantified so much of the assessment that currently takes place is qualitative. This may not be a problem provided that a consistent approach is adopted. The fmdings suggested that BRE should not attempt to pass any judgement on this issue at this stage but that there was great value in developing a consistent process of appraisal by establishing a protocol capable of aiding the presentation of information whether in planning negotiations, public consultations, technical reviews or assessment.

It was felt that implementing an assessment only on those issues where consensus can be reached would lead to a piecemeal methodology that failed to assess the overall impact of a building. This would lead to substantial and justifiable criticism. This emphasis on the process rather than the product, which formed a key recommendation of the consultants, avoids the need for subjective judgements to be made. When the findings where discussed by an expert panel of planners, designers and conservationists there was unanimous support for this recommendation.

This solution seeks to elicit a set of simple statements on a number of issues relating to the design process. Examples might be:

1. **How have you considered the context of your development in the design process?** This could include reference to local and vernacular styles; regional characteristics; surrounding uses/forms of buildings; creation of urban / public space.

2. **What is the zone of visual impact?** This could indicate range of distances and directions form which the development will be seen and the duration of view under normal circumstances; relative heights to neighbours and local topography; the need for visual statements; appropriateness of design details.

3. **How have you considered the relationship of the function of the development to its form?** This could cover relationships of the function to design and surroundings; relationships of internal / external environments; legibility of design and form; safety and access issues.

By asking for simple statements such as these and guiding the content required, much can be determined about the degree of thought that has been given to these issues during the design process. It also makes it easier for others to understand the reasoning behind design solutions by defining a common language.

In addition, the study produced a range of consensual criteria and identified many of the gaps in these. This highlights the need for ongoing research in this area including discussion with the numerous groups of interested parties. It could also lead to better quality planning guidance. BRE is exploring these requirements further.

4. Weighting of environmental issues

BREEAM currently assesses issues within three categories - Global, Local and Indoor. A rating is awarded based on the number of credits achieved in all three categories to encourage a balanced approach. In addition there is a degree of weighting given to issues by the number of credits awarded for each. The scale as it stands, however, can not be seen as a scientifically rigorous one and for this reason BRE has, for some time, carried out research which is ongoing into assessing the environmental weighting of the issues assessed.

Research was carried out for BRE by KPMG Management Consulting in 1992 to explore the potential for carrying out some form of weighting in the updated BREEAM being prepared at that time. Although this did not to lead to the inclusion of a rigorous weighting in the new version, it did flag the potential routes that could be explored. The study found three basic approaches which could be adopted for assessing the relative importance of impacts relating to building performance:

- Qualitative assessments are generally based on subjective judgements to determine performance. In each case guidance or expert judgement is used but a high degree of subjectivity remains. The potential for bias is an appreciable problem in such assessments.

- Quantitative assessment techniques have been developed in response to the demand for a more scientifically rigorous assessment. Such methods exist for many environmental impacts although not all, but give little help in deriving a rating methodology. They are useful in judging single issues but do not help in comparing relative importance of issues.

- Monetary valuation of environmental impacts faces the basic problem that many environmental ‘goods and services’ are free. There is no market operating to determine a price. A number of techniques exist to aid valuation of such impacts.

  - Market Value approaches are based either on the decreased value of output and increased cost to repair environmental damage or replacement costs.
  - Household Production Function methods use expenditure on complementary or substitute goods as a means of valuing a non-marketed environmental good. The primary method for doing this in buildings is preventative expenditure i.e. the cost of taking steps to avoid the damage.
  - Hedonic Pricing methods rely on the increase in property value as the basis for evaluating environmental benefits and so provide a measure of the willingness to pay for minimisation of environmental damage.
  - Contingent Valuation methods consist of asking people in a structured way how much they would be prepared to pay or receive in compensation for a specific change in environmental quality.

The study concluded that experience in the practical application of weighting in environmental assessment was limited, making it impossible to include a rigorous assessment in the update at that time.

In 1993 Davis Langdon and Everest carried out further research for BRE on the weighting of environmental issues. This was aimed at moving towards a robust and validated scale of the impacts covered by BREEAM. The study used the monetary approaches to attempt to provide a figure for each issue that could simply be added to give an overall monetary rating for the building. The study used a cause/effect matrix to enable multiple causes such as fuel consumption, recycling and site ecology to be broken down into single quantifiable effects such as CO2 emissions, resource depletion and an ecological index value. Such single effects can then be given a quantifiable value which can be summed to give an overall score for a building in respect to that effect. An effect fingerprint can be produced from this data to give a visual indication of the buildings impacts. By giving each effect a monetary value an overall environmental cost can be achieved for the building. Global and resource issues were relatively easy to both measure and value in monetary terms as the research data available is extensive. However, there is a marked lack of data on local and indoor effects. This flagged the need for research to be concentrated in these areas if BREEAM is to make use of such a method.

In the absence of such a scientifically robust methodology BRE used the Ecopoints system ,developed and subsequently refined by PRe Consultants, in the Office and School Toolkits. This provides a mixed quantitative and qualitative approach. The results are open to criticism but BRE believes that they provide a sensible indication of the areas which require most attention. They are used in the Toolkit to highlight priorities and are not an attempt to provide a rigorous quantification of the environmental effects. As such, they are not appropriate in their current form to a formal assessment method such as BREEAM. Within the Toolkits economic impacts of issues are also considered in terms of direct costs. All issues assessed are presented in the form of cost and environmental fingerprints which allow priorities to be made quickly and easily, possible actions to be explored and action plan developed and monitored. Figure 1 shows the structure of the School Toolkit which is a software tool. This has received strong interest and support in business circles and demonstrates a way of increasing the relevance and take-up of industry tools such as these.

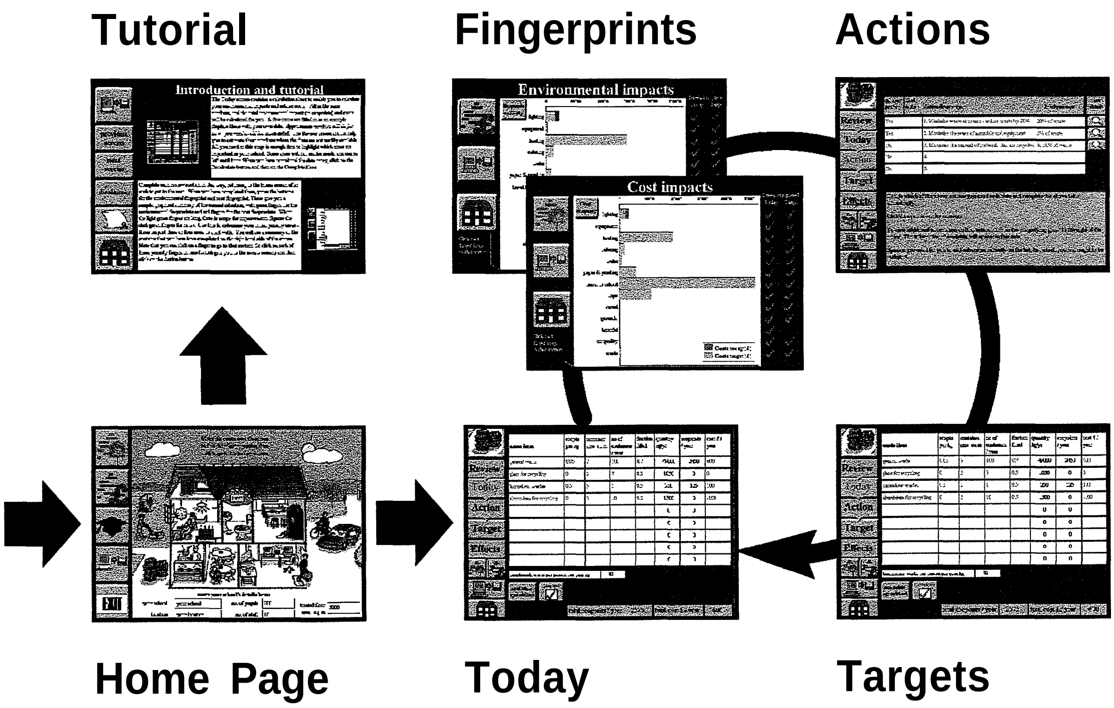

Figure 1 - Structure of the BRE School Toolkit

BEES, recently launched in the USA [13], provides a further example of a method that allows measurements of both cost and environmental impact. The benefit of this approach is that it allows individual designers and their clients to weight the importance to them of these issues by setting their own priorities with quality information.

BRE is currently carrying out a study aimed at establishing the degree of consensus that exists on the broader range of issues relating to Sustainability. Interest groups have been brought together to discuss and weight a range of issues derived from an Internet search. The issues covered are, therefore, representative of those relevant to policy and practice in society, government and business. The project has not reached the stage where any analysis can be presented as the discussion groups are still proceeding. Preliminary findings have shown a surprisingly strong consensus on many issues throughout the range covered. The work is unlikely to lead to a set of firm consensus weightings at this stage although there are promising indicators for a future stage. It should pave the way to more in-depth studies and will help to guide BRE on weightings for new versions of BREEAM.

5. Conclusion

BREEAM has worked well in influencing the design of new buildings and especially offices. Experience gathered from the development and operation of the methodologies over the last six years, together with the research carried out on areas not yet covered, have highlighted the strengths and weaknesses in current BREEAM versions in achieving their aim of stimulating environmental improvements in the UK building stock. BRE's ability to include new issues within such tools in a meaningful and practicable way is being expanded.

The current work being undertaken at BRE to revise the methodology for offices will address many weaknesses through a substantial expansion and restructuring of the method. It will also widen the range of issues beyond the buildings envelope and begin to make links to other areas of concern in terms of sustainable development. The revised method is due to be launched later this year. It will provide the basis for future revisions and additions to the BREEAM portfolio. It will also guide future development of related industry tools by BRE to enable construction to make a full contribution to the achievement of sustainable development.

Sustainable maintenance in transition economies

M.Katavić, I. Završki, A. Cerić
Department of Construction Managment, Faculty of Civil Engineering, Zagreb, Croatia

Abstract
The problem of maintenance has been considered in European and world scientific circles for a long time. This is because structural changes in investment go in hand to hand with economic development and business advances. The level of investment in the construction of new structural projects is constantly decreasing and the level of assets invested in the maintenance of existing buildings rising. Experience shows that usage, maintenance and reconstruction costs far outweigh the cost of initial construction.

Much research has been done in this field, but maintenance problems differ from country to country. Differences are particularly noticeable in the average age of the building, its original quality, technological approach and materials used in its construction, climatic characteristics, type of ownership, economy of the country in question etc. Seven years ago, Croatia changed its economic and political system from socialism and a state-run economy to a market economy, thus bringing the problem of sustainable maintenance into the focus of scientific and professional research.

The paper reviews the full scope of issues related to the maintenance of buildings in the Republic of Croatia in general, and in its capital, Zagreb, in particular. The districts of Centar, Novi Zagreb, and Tresnjevka have been taken as samples, being historically and architecturally very different. Each district, however, proved to be a very homogeneous sample regarding the main characteristics of buildings, and can therefore represent a model for setting priorities for sustainable maintenance. Analysis of the economic and technical indicators within the life cycle analysis may indicate the unjustifiability of further maintenance or full reconstruction of a building. However, the historical, cultural and architectural values of the architectural heritage of any city must be preserved, and Zagreb all efforts in this respect are being exerted.

A new model for maintenance sustainbility is being developed at the Faculty of Civil Engineering which is especially adjusted to the specifics of transition countries, one of which is Croatia.
Keywords: sustainable maintenance, buildings, transition economies, heritage

1 Introduction

The problem of maintenance has had high priority in European and world scientific circles, as the economic development and progress of a country changes the structure of investments. The proportion of investment in the construction of new buildings continuously decreases as investment in the maintenance of existing structures increases [1].

This is especially the case in old city centres. Analysis of economic and technical indicators within the life cycle cost analysis may indicate to the unjustifiability of further maintenance or full reconstruction of a building [2, 3]. However, the historical, cultural and architectural values of the architectural heritage of any city must be preserved, and in Zagreb all efforts in this respect are being exerted.

The problem is how to preserve the original appearance of the building and, at the same time, ensure the safety and quality of usage. Sustainable maintenance implies that buildings are to be renewed in a way to enable people and communities to provide for their social, economic and cultural well being without compromising the ability of future generations to fulfill their needs and preserve their heritage.

The sustainable maintenance problem is very complex, and becomes a serious challenge to researchers in transition countries. These processes have fully emerged in Croatia which has embarked on the road to market economy and private ownership.

2 The Problem of Maintenance of Buildings in Croatian Cities

To make possible an understanding of the problem confronting municipal authorities and the population in Croatian cities in their efforts to ensure sustainable maintenance we first need to explain the specifics of the condition inherited from the past system.

The major part of the housing space in Croatia was privately owned until 1945. After World War II, the communists come to power in former Yugoslavia and nationalised all private property. People owning several flats or houses were left with a single large (5- or 6-room) flat or two smaller (1- to 2-room) flats, with the remaining space being given to new right-to-use tenants. Other real estate, like land, factories, retail outlets etc. became the property of the Yugoslav state which took over their maintenance and management.

The maintenance of buildings in the past has been nonsystematic and without planning, with a significant difference in treatment of housing buildings and public buildings (theaters, schools, hospitals, courts, administration buildings etc.).
Public buildings were under the direct jurisdiction of respective ministries (culture, education, health, administration etc.). There was always a shortage of funds for their regular maintenance, and repairs were undertaken only when it became critical. Partial or integral reconstruction of a building would then be undertaken. According the data from 1995, 5% of the total funds earmarked the maintenance of public buildings were spent on regular maintenance, and 14% on repairs. Investments in reconstruction represented 8 1% of the maintenance funds which amounted to US$53.5 million [4].

The housing space was shared between the real owners of flats and the right-to-use tenants, with identical rights as the real owners although the flat was either state- or company-owned. The right-to-use institution was specific for the socialist system in

Yugoslavia and has a strong impact on the maintenance of housing buildings. The users on housing blocks were not bound to maintain the common parts of a building (roof, staircases, facades etc.) since it was so-called social ownership.

The state, via its funds, contributed to the maintenance of housing buildings in the form of regular maintenance (16%), reconstruction (39%) and repairs which included emergency interventions (44%). The amount thus spent in 1995 was US$44 mil. [4].
After 1991 and the break of Yugoslavia, new socio-economic relationships were established in Croatia. The law on the purchase of flats has enabled the former right-to-use tenants to acquire ownership of real estate under very favourable conditions. The maintenance of all buildings in the Republic of Croatia with two or more co-owners is regulated by the Law on Ownership Relations which imposes on the new owners the financing of the maintenance of buildings. For instance, the costs of renewal of the facade on a 3-storey high building in Zagreb, built in the 1930-s average approximately US$150 000. The Law was enacted in 1996 and started being applied some months ago.

However, the middle class population has been hit by the war and war damage, as well as the economic transition, and can hardly provide for the renewal of dilapidated buildings in which they now own flats. Such financial burdain will force numerous owners to sell their flats and move into smaller ones. Owners of flats in centres of cities, where the buildings are predominantly old and require more maintenance, will probably try to move to newer parts of the city. In all, after fifty years, housing has again become an economic category.

3 Review of the Housing Space in Croatia

The age of the housing space in Croatia is relatively high, with over 36% of the total space being built before 1960. Of this, 23% were built before 1945, and the rest during the 15 post-war years. The quality of these latter ones was significantly inferior, creating additional maintenance problems.

Table 1. Age structure of housing space in Croatia

CONSTRUCTION YEAR	NUMBER OF FLATS	[%]
do 1918	223,004	14.2
1919-1945	147,769	9.5
1946-1960	199,697	12.7
1961-1970	329,937	20.9
1971-1980	379,876	24.3
1981-1985	156,630	9.9
after 1985	132,812	8.5
Total	1,575,644	100

Source: The 1996 Statistical Yearbook of the Republic of Croatia

As the table shows, over 63% of the total housing space in Croatia has been built during the last 35 years [5]. It was normal in the socialist system for the state to build new housing blocks in new city districts, while systematically neglecting the existing housing space composed of old, pre-war patrician buildings for which maintenance there was no funds. They were occupied by either the owners of flats or the right-to-use tenants and such flats were maintained depending on individual needs, ambitions or financial strength, but without any obligation from the tenants.

Although neglected and in poor condition, these buildings have to be preserved for their historical, cultural and architectural value, while ensuring the basic requirements for safe and quality usage.

Zagreb became a free royal city in XIII century and has as rich history. Its old core has numerous baroque buildings from XVI and XVII century, making the situation in Zagreb more complex. This is the reason that motivated the authors to look for conditions for the application of sustainable maintenance on the Zagreb example.

3.1 The Zagreb Case

We shall start the analysis of the building maintenance problem in Croatia using the example of Zagreb, its capital. In total in 1994. there were 294,184 flats in Zagreb.Their age is relatively high with over 71,201 (24.2 %) of the total being built before 1945 (22,534 flats (8.8 %) being built before 1918). In last 25 years in Zagreb only 24.7 % of total housing space was built, mostly in new Districts like Novi Zagreb. The table below shows the different structure of expenses for maintenance of buildings according to age.

Table 2: The structure of maintenance costs of building according to their age

Housing buildings	Large and high housing buildings	Housing buildings with up to 4 storeys with over 20 flats	Small buildings (cultural heritage)
Age, years	20-30	5-15	70-l 50
Quality of housing	poor	good to very good	average
Intensity of maintenance	low	medium	relatively high
Maintenance expenses	relatively low	medium	high
Maintenance			
Emergency repairs, %	30	30	5
Services & inspections	10	4	1
Small repairs, %	25	40	15
Large repairs, %	25	20	75
Removal of damage, %	10	6	4

For our research the sample consisted buildings in three districts – Centar, Novi Zagreb, and Tresnjevka – which are historically and architecturally very different. All three districts represent a very homogeneous sample, and cover three important groups of housing buildings in Croatia, and can serve as a model for setting priorities in sustainable maintenance.

Table 3. General analysis of maintenance of housing buildings

DISTRICT	CENTAR	NOVI ZAGREB	TRESNJEVKA
Population	51.810	127.645	125,910
Number of buildings	2.026	1.691	1,310
Number of flats	12,000	3 1,000	35,000
Living area, m^2	972,480	2,0 15,000	2,275,000
Annual maintenance costs, US$	4,563,000	2,526,700	2,099,200
Age	70 - 150	5 - 40	20 - 30
Average costs, US$/$m^2$	4.7	1.3	0.9
Average costs US$/head	88.1	19.8	16.7

Source: Archives of the Municipal Housing Authorities for 1994

The whole of the Centar District is a protected city centre, with the majority of buildings from the second half of XIX century or early XX century. The buildings normally have four storeys, with retail outlets or office space in the groundfloor. Structurally, the buildings consist of walls in masonry, and floors of timber beams. The roofs are pitched with timber structure and tiles. Due to the unresolved maintenance system in the former system their state is relatively poor.

The Trešnjevka District is divided into two parts. The older part, with buildings 25 to 30 years old, consists of buildings with 10 to 20 flats each. Structurally, the buildings have a reinforced concrete (RC) framework with flat roofs unfit for walking. Most of the maintenance costs is spent on the roofs. The newer part emerged some ten years ago, with four-storey buildings with RC walls and floor slabs and pitched roofs.

There was no significant investment on maintenance in this newer western part of the district. Novi Zagreb is entirely made of large housing blocks and skyscrapers erected during the period of expansion of housing construction from 1960 to 1980. Buildings have an RC framework and flat roofs.

Table 4. Review of expenses for maintenance in three Zagreb districts

TYPE OF WORK	CENTAR [%]	TRESNJEVKA [%]	NOVI ZAGREB [%]
Emergency repairs	6.6	39.0	32.0
Services and inspections	0.8	4.0	8.3
Small repairs	13.7	26.4	22.5
Large repairs	78.0	30.5	26.4
Damage repairs	0.3	0.1	10.6
War damage	0.6	0	0.2
TOTAL [%] us $	100 4,563,000	100 2,526,700	100 2,099,200

Source: Archives of the Municipal Housing Authorities for 1994

It is clear from the structure of expenses that the Novi Zagreb and Tresnjevka districts have high expenditures for emergency interventions, while the expenses for large repairs and reconstructions make a minor part of the total expenses for maintenance. Such a structure of expenses is very unfavourable and in the long term drastically increases maintenance costs.

The structure of expenses in the Centar District shows that most of the expenses go for large repairs, which in 1994 amounted US$3.5 mil. Such a structure reflects an increased care for the old city centre, but is still insufficient. For instance, it was planned to spend US$1.8 mil. on the renewal of facades, but due to lack of resources only US$540,000 was spent.

Typical large repairs include facades, replacement of old water supply and sewerage installations, roof repairs, internal renewal of staircases, introduction of central heating, repair of structural elements etc.

According to data from 1994, US$2.3 mil. was spent on the maintenance of housing buildings in the Tresnjevka District. The highest percentage of this was spent on emergency interventions for the repair of water supply and sewerage, central heating, elevators, roof repair, and structural repair, particularly bearing walls.

Data given in Table 3 on the maintenance of housing space in the Novi Zagreb District show that most of the funds were spent on emergency interventions and large repairs. This points to the fact that insufficient attention is paid to regular maintenance, which results in frequent occurrence of large damage.

In general, of the planned funds most expenses went for emergency interventions on water supply, sewerage and central heating installations, then for the repair of roofs and elevators.

The given data confirms the fact that the cause of the poor condition the buildings in Novi Zagreb are in is not only the lack of regular maintenance but also due to the inferior design, constrution and maintenance of installations, poorly designed and constructed flat roofs, as well as poor quality and age of elevators.

The main requirement of rational maintenance implies comprehensive reconstruction after which only regular maintenance would be required. Investments in such reconstructions, particularly in parts of installations and flat roofs, would pay back through savings in regular and emergency maintenance.

4 Model for Setting Priorities for Sustainable Maintenance

To set priorities in the maintenance of buildings, with the principle of sustainable maintenance in mind, one should define criteria for the valuation of individual works needed and decision making. Each criterion weighs each element of maintenance, and a total figure defines priorities. These criteria vary from country to country and are subject to continuous scientific research and upgrading.

Historical, aesthetic, cultural, material, and functional values of a building, its age and other elements are all criteria which should be included in any decision-making model for priorities in maintenance. All models are based on a consistent and objective valuation of set criteria and on the formation of an index defining priorities in maintenance. The more criteria taken into consideration, the more substance the decision made has.

Research to date has resulted in the formulation of several models for setting priorities in maintenance of buildings.

One of the most widely known models is the attributive approach to setting priorities in maintenance. This model was developed in 1993 at the University of West England, UK. The authors were Prof. Alan Spedding, prof. Roy Holmes and Dr. Geoffrey Shen. Their starting point was a comprehensive study of the existing state in defining maintenance priorities by local British authorities and an analysis of the priorities setting models published to date. From the practical aspect, the model is simple, and from the manager's standpoint flexible enough. The very process of making decisions is transparent enough to enable the participation of the users of buildings in defining priorities.

When defining priorities in planned maintenance, the decision makers should analyse the condition of the building from various aspects, such as technical, political, financial, social, economic, and legal. After taking into consideration the above aspects, the criteria are defined and weighing factors applied. Besides standard criteria, special criteria also occur, such as legal aspects, maintenance policy, diverse informal pressures and others. Sometimes these special criteria have more influence than the standard ones and are decisive in decision making.

Always the first step in planned maintenance of buildings is defining structural and nonstructural elements which require replacement or repair works [6]. The task on the model for defining priorities is to sequence consistently the defined maintenance works according to their overall significance. All models are based on an as consistent and objective weighing valuation of planned works as possible, and on the formation of a cumulative index which defines maintenance priorities.

Let us define *n* criteria – $C_1, C_2, \ldots, C_i, \ldots, C_n$ – and let their relative significance or relative weight be defined with $W_1, W_2, \ldots, W_i, \ldots, W_n$. If we label with j the work on the replacement or repair of a considered element, then for each criterion we can valuate this work, or the significance of this work relative to the set criterion. We shall label these values with $S_{j1}, S_{j2}, \ldots, S_{ji}, \ldots, S_{jn}$. The cumulative index, called the index of priority for work *j*, is derived applying the following simple expression:

$$I_{pj} = S_{j1} \times W_1 + S_{j2} \times W_2 + \ldots + S_{ji} \times W_i + \ldots + S_{jn} \times W_n$$

This way, each work on the maintenance of a building is valued by a single parameter, and prioritisation is carried out by simply arranging the indexes in a descending order.

A new model for sustainability of maintenance is being developed at the Faculty of Civil Engineering in Zagreb within a scientific project which is based on the above described attributive approach and is adjusted to the specifics of transition countries one of which is Croatia. When defining criteria, the specifics of Croatia as a transition country, but also a country with rich cultural and architectural heritage, were taken into consideration. Besides this, the model will attempt to consistently weigh the proposed criteria.

5 Conclusion

This paper presents three types of urban districts in Zagreb, with buildings of diverse historical, cultural and architectural value. While some buildings are in poor condition and economic parameters indicate that these could be demolished without additional consideration, other which form the old urban centre and represent the wealth of all the citizens and even country should by all means be preserved.

The problem is how to preserve the original appearance of a building, and also ensure the safety and quality of usage. Sustainable maintenance implies that the buildings are to be maintained so as to provide the people and communities with social, economic and cultural well-being without compromising the ability of future generations to meet their needs and to preserve their heritage.

No scientific research has been undertaken in Croatia to date which covers the management and maintenance of buildings. International experience in this field cannot be directly applied since each country has its own specifics in problems to be overcome by maintenance, such as the age of buildings, their initial quality, applied technology and materials and economic transition, like in Croatia, which reflects on the financial potential of the population and municipal authorities.

The problem of sustainable maintenance is itself very complex, and becomes a real challenge to scientists in transition countries that have changed the political system.

This is why it is not possible to apply directly the available knowledge on maintenance management to the Croatian case, but the existing knowledge and possibilities should be adjusted to our requirements and specific conditions.

Eindhoven University of Technology, The Netherlands

Abstract

Sustainable Development and Sustainable Building is mainly a question of (human) environmentally-conscious Organisation and Management.
Criteria are needed in order to capture the best practices in the field. Therefore we developed modells and methods, which help to choose the most adequate practices.
Invention of key research activities can be brought up by screening the current problems in the light of the Meta-Modell Integral Bio-logical Architecture which at the same time will help to identify the gaps in the field of research.
By the use of the Method Holistic Participation - MHP it is possible and stimulating to work multi-and interdisciplinary.
With the help of MHP consensus can be supported systematically and even reached in order to find a research agenda with those priorities, which have a high probability to be able to contribute essentially to Sustainable Development and Sustainable Building.
Managing this task in the frame of one of the most urgent world problems - Building in its nowadays way as a danger for Environment and - perhaps paradoxical - even for Humankind as well, it is at least strongly connected to the Legal and Procurement Practises, which similarly - as described above - can be approached, especially by the MHP concerning the Aspects of Conflict and Dispute Resolutions.
Since a certain Indoor Climate is one of main reasons to build it, will be most conditional to link Management with the demands of and for a healthy Indoor Environment, which finally needs also a healthy Outdoor Environment. For the balance between them the Strategy for Optimising can be applied. But Materials and Technologies have to be choosen properly. For this a special Matrix can be offered which at least as a rule of thumb can function as a further organisation aid.
Together with a view on the flanking subjects Management and Organisation can effectfully be runned by globally thinking while locally acting and planning on short as well as longterm, as the most important demands for reaching the aim of Sustainability.

Sustainable Building Organisation

Sustainable Development and Sustainable Building is mainly a question of (human) environmentally-conscious Organisation and Management.

Criteria are needed in order to capture the best practices in the field. Therefore we developed modells and methods, which help to choose the most adequate practices. Invention of key research activities can be brought up by screening the current problems in the light of the Meta-Modell Integral Bio-logical Architecture which at the same time will help to identify the gaps in the field of research.

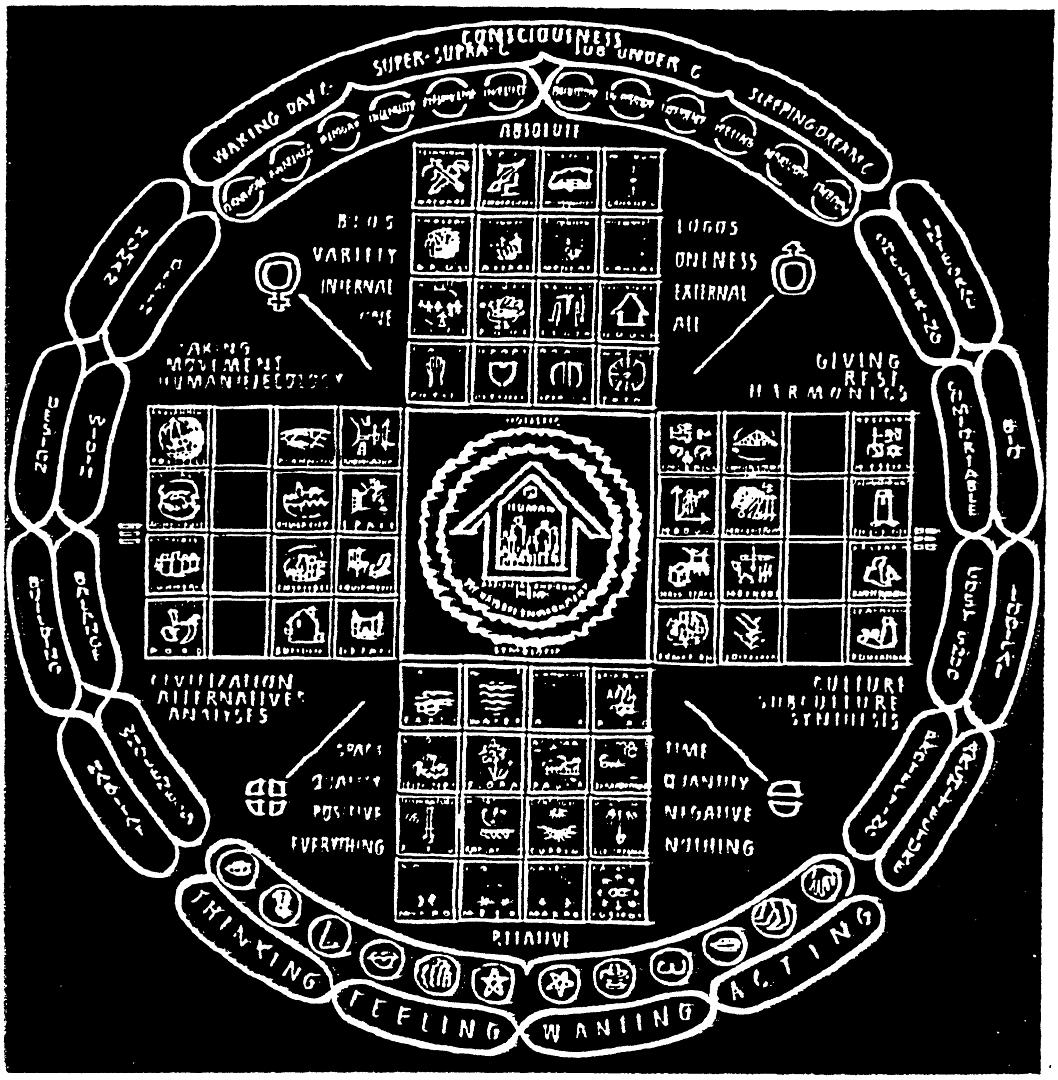

Figure 1
The Meta Model Integral Bio-Logical Architecture shows the factors and their interrelationship concerning Building between Humankind and Nature.

By the use of the Method Holistic Participation - MHP it is possible and stimulating to work multi-and interdisciplinary.
With the help of MHP consensus can be supported systematically and even reached in order to find a research agenda with those priorities, which have a high probability to be able to contribute essentially to Sustainable Development and Sustainable Building.

HOLISTIC

PARTICIPATION

Figure 2
The Logo of the Method Holistic Participation symbolizing the rol play's of co-operating (expert) persons or teams, who in a weaving rotation - even starting with opposing opinions - can come to consensus.

Managing this task in the frame of one of the most urgent world problems - Building in its nowadays way as a danger for Environment and - perhaps paradoxical - even for Humankind as well, it is at least strongly connected to the Legal and Procurement Practises, which similarly - as described above - can be approached, especially by the MHP concerning the Aspects of Conflict and Dispute Resolutions.*

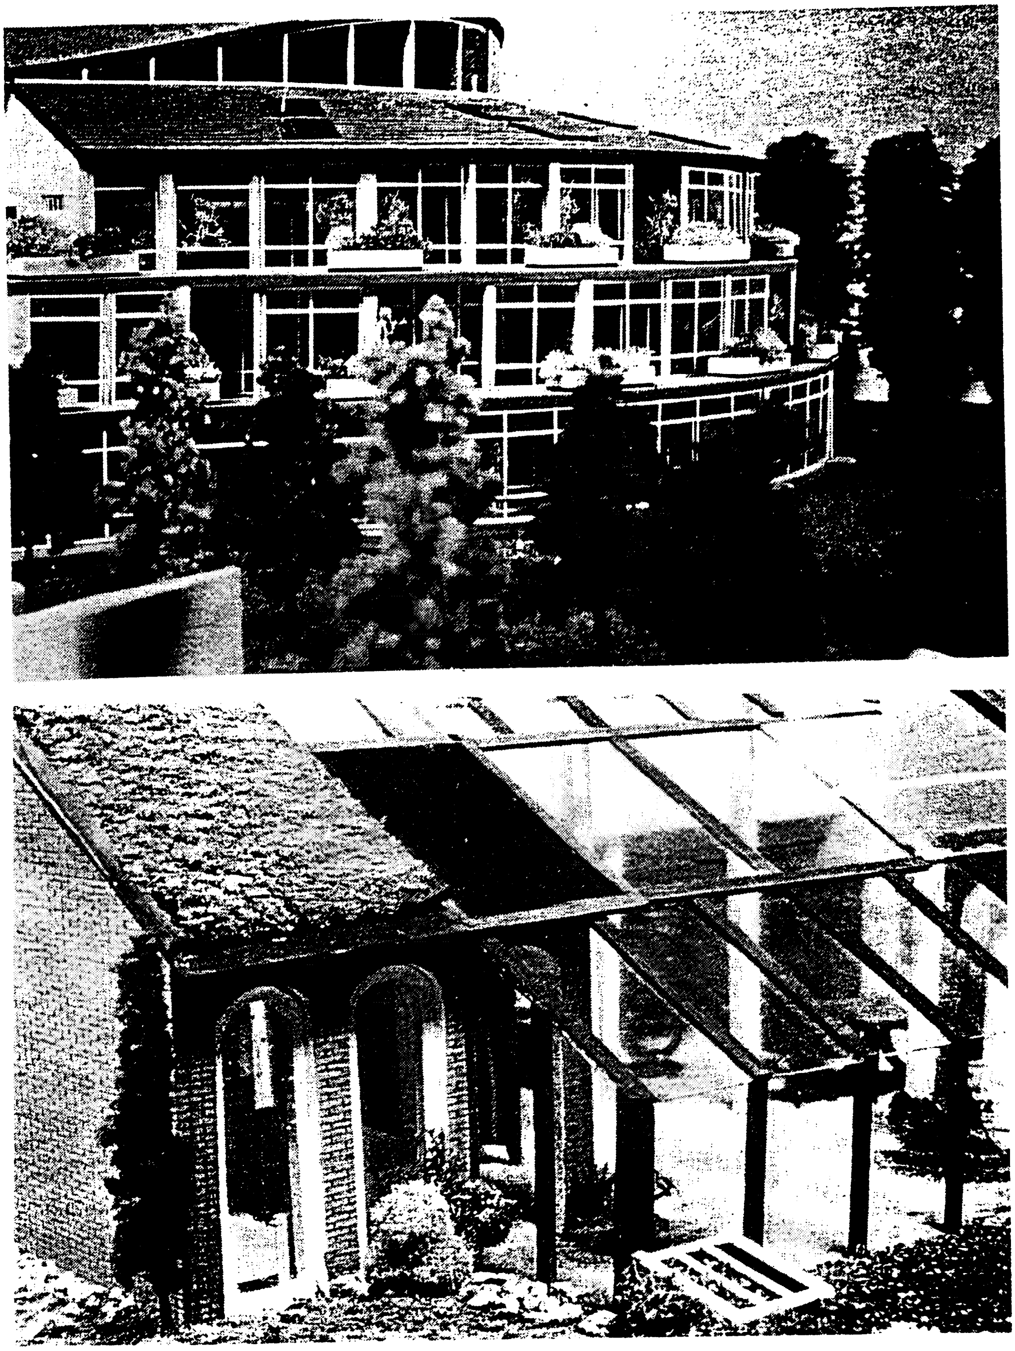

Figure 3
Attempts towards Sustainable Building: Various examples of human-ecologically, healthy and environmentally-conscious holistic concepts, realised in projects.

Since a certain Indoor Climate is one of main reasons to build it, will be most conditional to link Management with the demands of and for a healthy Indoor Environment, which finally needs also a healthy Outdoor Environment. For the balance between them the Strategy for Optimising can be applied. But Materials and Technologies have to be choosen properly. For this a special Matrix can be offered which at least as a rule of thumb can function as a further organisation aid.
Together with a view on the flanking subjects Management and Organisation can effectfully be runned by globally thinking while locally acting and planning on short as well as longterm, as the most important demands for reaching the aim of Sustainability.

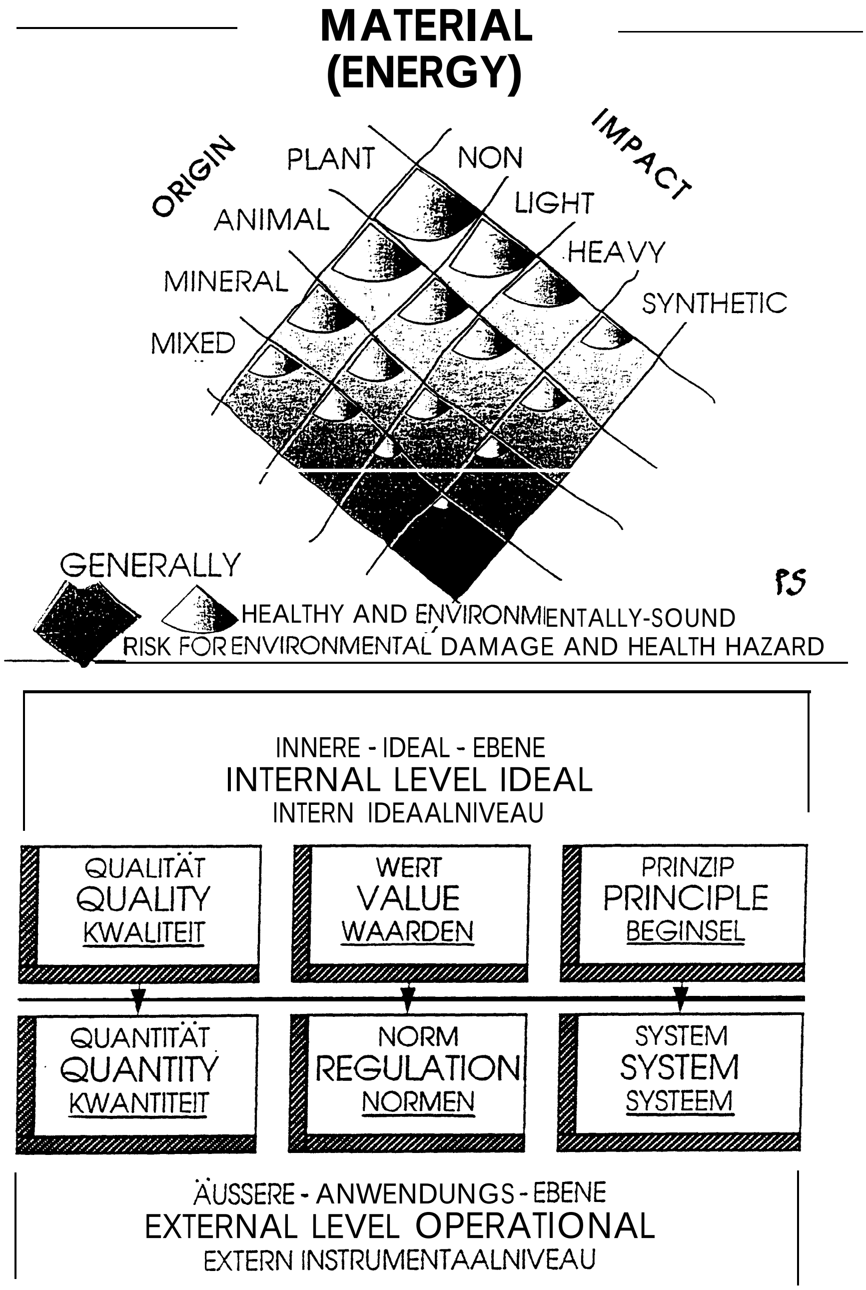

Figure 4
The evaluation of the impact of the use of materials (and energies) on health and environment is already roughly possible by the means of the Instrument Material and Energy Choice Matrix. The scientific approach towards the discussed problems should be supported by Principles, Values and Qualities.

Tentative application of the ECE Compendium of Modet Provisions for Building Regulations

G. Blachère, AUXIRBat, France

Abstract :

The ONU ECE Compendium of Model Provisons for Building Regulations issued in 1996 proposes for the first time in the history of regulations a chapter 4b dealing with “requirements for a building compatible with sustainable development”.

It proposes to characterize materials used in building by indexes of :

Renewability of the resources
Difficulty in disposing of the wastes
Recyclability

In a French study about building briefs, written in terms of requirements, a tentative application of this characterization has been made.

The characterization of various materials using these indexes gives rise to difficulties among the producers.

Are we prepared to face these ?

A. Presentation of the problem

1. Consumption of building materials create a large part of the problem of sustainable development because the mass of these consumed materials is enormous.

In what follows, we will put aside the public works, specially important in agregates consumption. We will also not take into account the warmhouse effect of heating or air conditionning devices.

For example, the figures of the yearly consumptions of some main building materials are :

Ciment : 1.2 billion tons
Timber : 3 billion cubic meters

These are today’s figures, corresponding to a human population of less than 6 billion people, among them less than 1 billion are members of the affluent society.

When the world population will reach the 10 billions, and if the standard of life of the poor significantly increases, these figures should be increased about four times.

The impact of building product consumption when building, and of building refuses when demolishing is thus really considerable. What creates a great concern.

2. To be efficient when dealing with such a problem it is necessary to avoid, as far as possible, gossips, but :

a) to use figured characteristics resulting of measures or classifications of the parameters contributing to the risks of endangering the sustainable development.

b) to deal with the various aspects of the problem as a whole, non foncussing on such or such aspect as demolition refuses disposal, or contribution to the warmhouse effect - because when using a material affects may be caused at all the facets of the sustainable development at the same time.

c) to try to propose solutions for improving the situation, which is very difficult, but unavoidable if efficiency is seeked. Putting in practice these soltutions may be the fact of "virtuous" clients and building people, conscious of the importance of the problem or of reglementary authorities, today at the national or regional level.

B.1.. .In the spirit of what preceeds, the author, at the demand of the Human Settlement Committee of the UN Economic Commission for Europe proposed a supplementary chapter to the ECE Compendium of Model Provions for Buiding Regulations 1991 edition :

Chapter 4.2 - Requirements for a building compatible with sustainable development,

which has been accepted by the Committee and published by the UN Press in 1996.

This chapter dealt with the characterization of the materials in consideration of :

their renewability

their recyclability

the biodegradability and non noxiousness of demolition waste.

In the year 1996, I had the opportunity to try to make application of these dispositions for ADEME, the French Agency for the environment and energy saving.

It was the opportunity of adding two other characteristics to those considered :

- The consumption of energy at the production
- The amount of energy recuperable at the combustion after demolition.

We also proposed classes for every character. Thus we came to the charectarisation guide below.

Two things at least are clear :

First, the limit between classes comprises a large part of arbitrary : in fact, as we will see below, it is at the application of the grid to a set of materials that the frontiers between classes will be set down.

Second, the classification of a material is not absolute, but depends upon national or local parameters :

e.g. Timber is renewable if measures are taken for reforesting,
Glass is recyclable if collect systems of waste of glass are organized,
etc.

Thus the grid of classification is variable in space and time.
But at a given time and place it is usable

B.2 The RCD PE grid of characterization

a) R - the renewability

3 classes are proposed :

R1 : Material complety renewable
It means : whose original resources is renewable
e.g. - Timber and wood when reforesting

R2 : Material partially renewable, e.g. gypsum plaster pannels with a wicker reinforcement

R3 Non renewable : practically any material except vegetable.

b) C for Recyclability

Cl Recyclable to the same product - e.g. - steel, aluminium

C2 Recyclable to another product, e;g. glass (from glass panels to bottles), concrete from structural concrete to road agregates

C3 Non recyclable - e.g. Polyester, reinforced concrete.

c) D for bio-Degradability of the products after demolition. For this character, what appears possible is simply to create a class D1: biodegrable and another but cut in two :

D2 Non biodegradable, non noxious

D3 Non biodegradable , noxious.

Examples of D1 , could be timber, textiles, some plastics.
Examples of D2 - stony or ceramic materials
Examples of D3 - Asbest cement, quick silver which shoud be excluded from the use and free waste disposal.

d) E - What is in cause here is the energy of production

The concern is not the warmhouse effect, but the consumption of limited natural resources.

Some production processes may be accomplished only with mineral or vegetable fuels. Others like steel fusion may be done using electricity which as in France, may be largely nuclear. This distinction should be done, but has not been undertaken here.

Three E classes are proposed :

El - Energy less than 2000kW per ton, e.g. timber, natural textiles

E.2- Energy between 2000kW and 5000kW per ton. Example given : concrete and reinforced concrete, gypsum plaster, ceramics.

E.3- More than 5000kW. e.g. ashphalts, some plastics.

It is clear that the classification is too rough and that class E2 should be split up.

e) E for energy produced by the combustion of wastes.

In this field 3 classes are proposed :

El Combustible without noxious effects of the combustion products, e.g. timber, textiles, some plastics.

E2 Not combustible, e.g. Stoneous, ceramics.

E3 Combustible with production of noxious gasses e.g. PVC, PU.

It is clear that this classification is in relation more with pollution than energy. The point should probably be reconsidered.

B3 At the end using the RCD PE grid, or better, with an improved grid of the same spirit, we have the means to produce a profile for any material.

Without being from far exhaustive, we will give here some examples of RCD PE profiles :

Steel : R3, Cl, D2, P2, E2

Comment : The fact that steel is D2 - practically non degradable, is compensated by the fact that it is from a long time recyclable. This proves that a character should not be appreciated on its own.

Glass presents the same profile as steel.

Timber's profile is : Rl, C2, D1 ,El ,P1

Comment - The fact for timber to be D1: biodegradable, is not important since it is C2 if the necessary dispositions for recycling are taken.

As for plain concrete the profile is :R3,C2,D2,E2,P2.

To get an end to these profile characteristics, we should note that, as generally in matters of profiles, it is not possible to condensate the profilen a global note, as a consequence of the diversity of the relative importance that may be given to the various characters at different places and times.

C. What to do for the sake of sustainable development ?

cl. "Virtuous" clients may use the profile to determine in their briefs which materials they oppose, they recommend, or compell.

And in the same way the building authorities may impose or refuse materials by the way of regulations.

But our experience is that when a lobby of producers of one material becomes conscious that its profile is apparently less favorable from those of competiting other materials, say plastics and wood in floor coverings, it shows a strong reaction that will probably impeed any public action, if not the diffusion of the profiles.

So the way of coercition seems to be unfavorable.

c2 Things being as they are, the best attitude may be to incite the improvement of the profile of a material, seemingly defavorized :

It is possible to act in many ways :

R. To reduce the consumption of non renewable materials using better building systems, better calculation methods, better combined use of various materials e.g. steel and concrete in structures.

To take measures to make renewability a reality : e.g. replanting forests.

C. To develop recyclability schemes, e.g. In Switzerland concrete is recyclable at the rate of 2/3.

E. Modernization of production may lead to drastic cuts in energy consumption at production. e.g. bricks and roof tiles.

To push for these measures, the menace of coercition could be maintained at the horizon.

But something should remain clear :

Today, building is fundamentally too expensive.

Measures in favor of sustainable development will not be accepted if they bring about cost rises. e.g. to use recyclable materials should lead to cost savings and not to the contrary.

Towards a more sustainable development : a model for the building sector production

J.Baillon, , C.Lipari,
Auxirbat, Paris, France.

Abstract
Nexus is an intelligent environmental model, developped by AUXIRBAT, whose research team is linked to several others belonging to the CNRS in France.
It has been used to build various scenarios whose purpose is to identify the degree of sustainability of different paths of building sector development.
In first place, it was noticed that the concept of sustainability could not refer directly to the building sector, for the reason that specific and scarcity problems generated by buildings are not very large, and also because the main problems for the future generation are the land-use aspect and the energy consumption, which are two items involving many other sectors.
Nevertheless, a methodological approach has been developped that shows on a long-term range a great difference in the impact of a « let things go their own way » scenario, and an interventionist scenario through the authorities action, either in regulations forms or by tax and incitative mortgages.
For the previous aspects described, Nexus Model provides data that are able to assess the cost-benefit of each considered path of the development of the building sector.
Keywords : Building sector, modelling, Sustainable development.

Main text

Introduction : Building crisis and sustainable development

Building sector and particularly housing sector in France have been passing through a crisis which origins go back to the end of 70's.
Until1 this date, stimulated by an important demand and helped by negative interest rates, building sector had reached unequalled levels in France (around 500 000 buildings a year started to be built). The delay -accrued between the two wars and strongly increased by the destructions of 2nd world war and demography evolution (((baby boom), rural exodus, immigration...) - had indeed to be cleared up.

Most of the needs were satisfied so that it seems normal that building rythms had come back to lower figures.
That impulse seems besides to be increased by another structural factor that contribute to the same phenomenon : the increase of bying cost for final buyer which brought a break in solvent demand.
The result of this situation is a stagnation and even a recession in current francs in all the building activity (-1,7 % in 1996) and the maintenance at a very low level of new buildings : less than 300 000 buildings and 15 millions m^2 started to be built for tertiary sector).

Even if the maintenance and the renovation activity have taken over the new building construction to maintain the activity of the sector (it represents now more than half of its activity), the drop in new buildings construction leads to an insufficient renewal of the total number of buildings. This brings local shortage situations and generates a wrong adjustment to the demand. The actual level of new construction, more particularly in social renting building sector, will not be able to provide durably acceptable life conditions for all the population, with the following consequences :

- more and more people will be excluded from decent housing owing to the lack of resources.
- as a consequence of the insufficient renewal of the number of buildings, technically and socially obsolete housing areas will remain, interfering with the modernisation of urban infrastructures.
- the lack of fluidity of the total number of buildings will not enable a sufficient mobility.

In front of this relatively pessimistic established fact, we wonder what could be the opportunity of the application of the concept of ((sustainable development)) to building sector.
Concerning this debate, the ((prospective approach>>, -as it enables the analysis of the margins of manoeuvre and the consequences of a «let things go their own way» policy on the future of the sector and its impact on the environment-, represents an assistance tool for decision-taking, very important help for the implementation of a ((sustainable development)) policy applied to building sector and more specifically to housing.
The NEXUS Habitat model, developped by Auxirbat within the Research Group OÏKIA of the CNRS[1], enables to detail by a quantitative way this prospective thought.

1 Scenario of possible evolution of building sector :

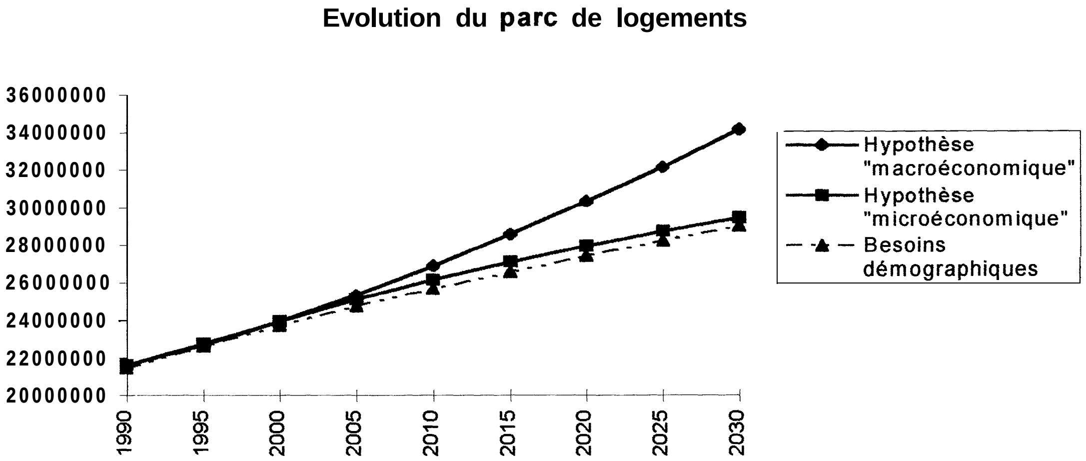
The building sector is very sensitive to greet macroeconomical parameters variations :

- the demand is a function of the income evolution of households, which also depends on the evolution of national wealth.
- real interest rates determine for a large part the loaning capacity of households and prime contractors.

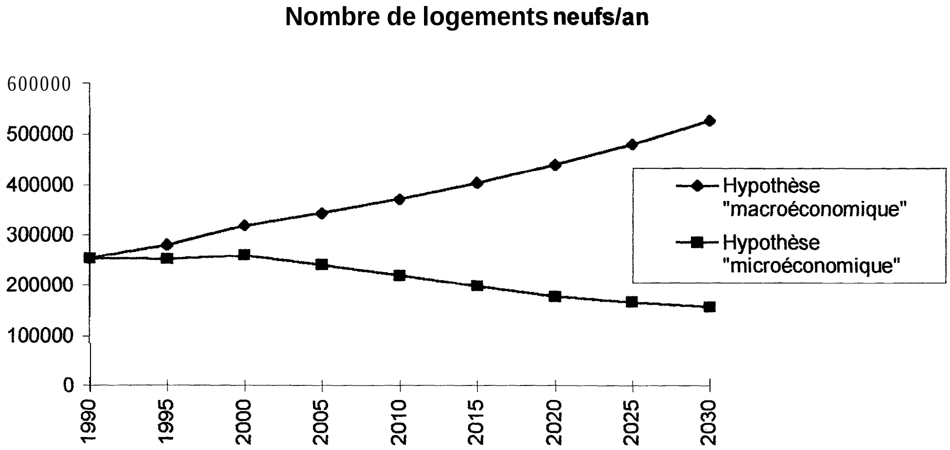
- the size and the orientation of public aid, which depends for the most on public finance, conditions the access to housing for the poorest populations.
- the evolution of relative productivity, which is a function of the technological and organisational innovative capacity of the sector, and which determines the evolution of construction costs.

The use of «Nexus Habitat)) model had enabled to outline the tendencies of the sector according to the values assigned to every proceeding variables within the scope of three contrasted scenarios.
The central question in a «let things go their own way» scenario in the environmental sphere is to determine the level that could durably reach the construction of new buildings within a middling growth economy, where most of primary needs in housing are satisfied.
To answer this question is difficult, because the results obtained by the modelisation are different according to the major macro-economical equilibriums and -on the opposite- to the behaviour of micro-economical actors and particularly households.

Graph 1



Graph 2



On the whole, the «let things go their own way» scenario shows us two images of the future in which the productivity profits and the qualification of labor would take a great place.

The first image is the one of a sector that finds its dynamism again, keeps on mobilizing a relevant part of investment, and increases built areas offered to the population, carrying along a more and more important occupation of the space, together with an increase of the agressions on environment, that are limitated but true.

The second image, more malthusian, is the one of a sector to maturity which continues to keep focus on the maintenance of a huge existing estate.

The improvement of life conditions here doesn't follow the increase of areas : it follows the improvement of the existing number of buildings.

Besides that, all the available area by inhabitant does not decrease comparing to 1990.

Nevertheless, this second image, almost more respectable for the environment as less «productivistic», should not bring a more important recession (in terms of turnover and employment) than the present one[2]. On the other hand, it presents the disadvantage to offer little margin of liberty to solve crucial problems such as poorest people housing, the elimination of ghettos, necessary evolution of urban transport...

From the energy consumption point of view, the two approachs are equal and show that in absence of measures, it will materially increase, mostly because of the increase of electricity consumption.

(3) datas producted by NEXUS - micro-economical approach

2 The normative scenario :

About the new construction rythm, it seems' difficult to go beyond the preceding micro-economical hypothesis.
In fact, this hypothesis leads only to maintain the lodging conditions of the 90's, with a renewal rate of the number of building of 3 %, that is to say a building duration of life of more than 3 centuries[3].
Most of the political measures that characterize this scenario would rather aim at improving the working of existing number of building.
These measures would mostly deal with the comfort and the health of the occupants, the renovation of frontages which interface part with city is very important, the inexpensive equipments in water (which cost should increase by 10 to 50 % to 2005), the domestic energy consumption and the associated carbon emissions.
The expected results are significative compared to the «let things go their own way» scenario since in the aggregate the energy savings in the residential sector could raise above 15 MTOE/year, while carbon emissions should be stopped at 70 % of the level of 1995.

3 The flexible scenario :

The previous scenario has the advantage of limiting to maximum the pression on environment, but represents the disadvantage of increasing the inflexibilities of the construction sector and of encouraging the stagnation of economy.
Compatible with a financial disengagement of the Nation -almost complete in the sector-, it doesn’t use the margins of manoeuvre thus enabled.
The major and structurant idea of the flexible scenario is to use this financial capacity to give a more dynamic and flexible content to the previous scenario.
All aids together, the intervention of the State on the sector is around 120-billions in the «let things go their own way» scenario, amount that should be reduced to around 30-billions in the normative scenario[4] .
The reorientation of the SO-billions difference between the two scenarios could be useful to finance 4 great projects :

- a substantial support to innovation, with the implementation of Research and Development programs within the framework of a public/private partnership. These programs could fit into technological field -with the objective of a drastic decrease in costs without deterioration in quality- and into socio-economy field, with the improvement of demand knowledge and of its potential evolution.
- a renewal policy of the existing buildings, specially by the destruction of poor-quality housing with serious social problems (particularly acurate in the new residential areas consisting of large blocks of flats, built less than 40 years ago).
- the reorientation of social housing to the less financially solvent categories.
- the renovation of infrastructures and of the urban organization that can be done thanks to the faster renewal of the existing buildings.

The main advantage of this scenario from a ((sustainable development)) point of view, is to increase liberty margins for the future by the mere fact of a more important dynamism of the buildings population, with almost the same level of negative impacts on environment as in the previous scenario.

Conclusions :

At present time in France, the <(sustainable building)) approach is very « environmentalistic » and brings the sustainable development to technical and quantitative norms (acoustics and heat comfort, recycling of construction materials, recovery of river water...), that have been made compatible with the rentability objectives.
An incitative policy is preferred to implement this practice : setting of a taxation incitation system and of subventions in order to give favour to the construction of <thigh-environmental quality » buildings ; commitment for environmental plan for firms ; sensitive actions to building contractors about the ((global cost» notion.

Besides that, the margins of manoeuvre are limited, in connection with the economical restrictions applied to environmental and social action (trade conditions, improvement of national firms competitiveness, building sector support...) ; in addition, available budget resources to stimulate environmental action seems to be less and less important when public aid is requested by priority sectors (Health, Education...).
Even if we can think about a « green revival » with an important agreement for users to pay for environmental quality so as to incitate the sector to innovate in this field, this scenario still produces social and territorial segregations.
In fact, it may contribute to the development of an expensive housing, that cannot afford a lot of people, and to restrict the possibilities of State social intervention.
This trend is consequently insufficient to move the building sector towards a sustainable development.
On the other hand, the innovation directed to costs decrease becomes -owing to the margins of manoeuvre it should bring- a motor for sustainable development in building sector. Joined to public aids reorientation to make solvent a part of the demand, it could give a new stimulation to the sector, that is necessary to avoid perpetuating urban ghettos, to reorganize the structure of large blocks of flats areas without any character in the suburbs , to improve the poorest people -lodging within this framework, the revival of new buildings construction if done with a real architectural research, concerning the building as well as surroundings, that will be able to contribute to the modification of urban landscapes. This new dynamism would be also a key factor in changing space distribution of activities, reducing the «zoning» popularized by «Athens Charter)) and in establishing again the complementarity of transport means.
One could object that the search for productivity in the past was rarely undertaken with an improvement in architectural quality. That is true if the search for productivity is only made in order to reduce the costs, all process being constant : it is not the same at all if productivity profits are brought by innovation in products, process and production organization.

* * * * * * *

---

[1] Nexus Habitat is a sectorial model which gives a long-term projection of the evolution of building sector and its consequences on the energy consumption. It will be integrated to a general equilibrium calculated model IMACLIM. Presently, a macroeconomical equilibrium equation guarantees the coherence of the model.

[2] Provided that the whole Economy can find new tanks of growth.

[3] However, the margin is larger in non-residential buildings, as the duration of life is around 60 years.

[4] a 20-billions aid to poorest housing and a 10-billions aid to encourage energy savings in the existing buildings.

Scenarios and visions as tools for endurable changes in sustainability in society, organisations and the built environment

G. Molin
Molin Framtidsstudier, Gothenburg, Sweden

Abstract
The goal is sustainability and the means the changes that will enable it. For people to act consistently in favour of sustainability in society, organisations or in the built environment, three things are required: a technology that provides the opportunity for such action; structures/institutions in society, in organisations or in the built environment that support such action and finally a vision that supports such action by individuals willing to grab the opportunities created by different technologies. The vision guiding change activity should be rooted in the present world and in people's present set of values, as well be valid for several different futures. With the focus on sustainability in the built environment, I will show how communities and organisations can build their own scenarios and visions.
Keywords: scenario, vision, future, sustainability, built environment, organisation, change, method.

1 Introduction

For us to make changes in our behaviour, we often need a goal to guide our actions. Even when we have made changes and achieved our goal, we often fall back on our previous behaviour. In the pursuit of living in harmony with nature, we often fail to do so. Lifestyles intended to be in harmony with nature are often called the alternative lifestyles, as opposed to the more 'normal lifestyle which does not focus on it's relationship to nature. To be able to create lasting changes in sustainability in society, in organisations and in the built environment, living in harmony with nature needs to become the normal lifestyle, not the alternative one. The key to endurable change is having a clear picture where you want to go, leading you to look for signs and confirmations until you reach that point. The creation of that clear picture, also called a vision, will not only give you a direction, but also help make all the small decisions along the way easier. We can also simplify the decisions if we adopt a principle, but such a principle is not a vision. As for the early setters in North America "go west" was the principle in seeking the "Promised Land." They had a vision of this 'Promised Land', part of which was that if they went west, they would find it.

I see sustainability as a principle, not a vision. The questions are why should people follow such a principle and which vision can support it?

The reason for adopting the principle of sustainabilty today is that you will gain something tomorrow if you do. If you would gain something almost at once, the argument would be even more convincing. In the metaphor of *The Journey to the Future*, you are coming from somewhere with a certain speed and direction. Perhaps you even have a goal for your journey. The early settlers were coming from the east at the speed of a horse-drawn wagon with the "Promised Land" as their goal. They had a vision for their journey which helped them to overcome difficulties and to keep on going.

Strong motivation often comes from a vision of what we want to happen or not to happen. Today's struggle for the environmental have created a new word – sustainability. The message is that "the world will survive only if we apply sustainability to our every every action." That may be true, but is it a vision which can motivate the majority of the people in societies and organisations? I strongly believe not and the reason is that sustainability provides a negative focus on the future.

It is common knowledge in the world of sports that a team will not win if it only focusses on not losing. Winners gain strength from having a positive picture of themselves as winners. The vision which could motivate us to apply the principle of sustainability in every action must contain positive pictures of living a sustainable life and the fruits of such a life. The vision must tell us why it is better to adopt the principle of sustainability than continuing to live as we have. It must tell us what we will gain if we change our ways of doing things and look at the world with a new perspective? The majority of the people in the Scandinavian countries today would not see any immediate gain from such thinking. They probably only observe the difficulties in trying not to use the petrol consuming car or that ecological groceries cost more than the normal ones.

2 The three pillars for change

Three things are necessary to persuade people to act consistently for sustainability in society, organisations or in the built environment: a technology that provides the opportunity for such action; structures/institutions in society, in organisations or in the built environment that support such action and finally a vision that supports such action by individuals willing to grab the opportunities created by different technologies. The vision guiding the activity of changes should be rooted in the present world and in people's current set of values, as well as having validity for several different futures.

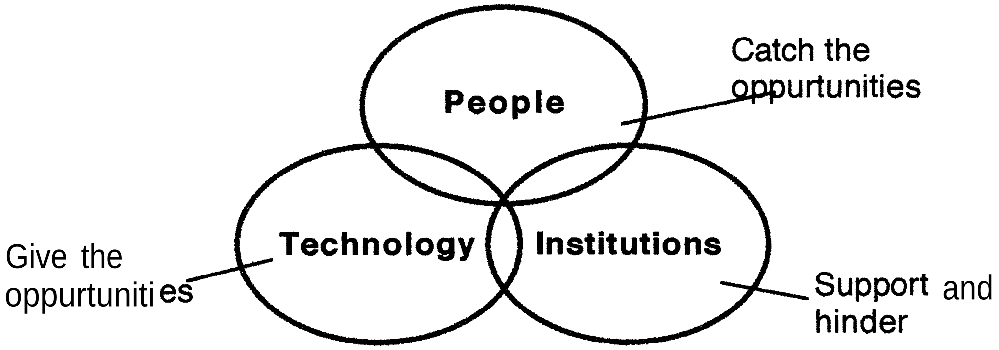

Figure 1. Co-operation between technology, people and institutions. [1]

What possibilities do we have for fulfilling the three pillars of change in the matter of sustainability? Do we have sustainable technology? Yes, *of* course! Are there people out there grabbing the opportunities which technology give us? *Some are and some are not!* Do the institutions support sustainability with regard to people's behaviour and technology? *Not enough!*

What conclusions can we draw from these answers? Firstly, that we don't need better sustainable technology. While the need for such technology remains large, what it needs is people who want to buy and use it. Secondly, some people are taking the opportunities and some are not. The immediate reason would seem to be that they don't believe in a society built on sustainability. That suggests a lack of vision or that they think it as too expensive without enough commensurate personal or economic gain.

2.1 People's values

People have different sets of values and therefore different ways of adopt new **technology and** of **making sacrifices for the benefit** of the natural environment. The **Kairo's Value Map,** KVM, **is a** multivariate analysis of **people's** values. It will cluster different values depending on their strength and on their relation to people's set of values.

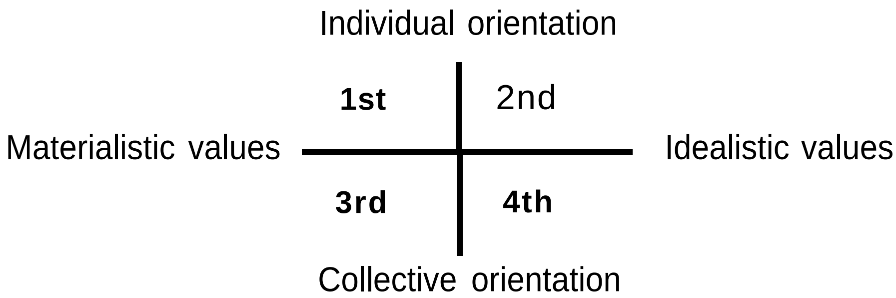

Figure 2
Kairo's Value Map, KVM [2]

If you apply the map to the population of Sweden (ages 16-65), most people willing to sacrifice for the benefit of natural environment will be found in the 4th quadrant and those most reluctant in the 3rd. You will find most people willing to try new technology in the 1st. In quadrants 1 and 2, you will find the most educated and affluent individuals. Of course these different value clusters need to be considered in designing new technology and in any vision for organisations seeking to attract customers and employees.

2.2 Institutions

Institutions and different structures in society, communities, organisations and the built environment either support or hinder deviating behaviour. The normality/abnormality of deviating behaviour depends on the values in the organisation. So called normal behaviour is both the outcome of people's values and of how different policies in company work as a system supporting and/or hindering certain behaviour. The built environment with it's infrastructure also influences people's actions by telling us what is regarded as normal.

I am convinced that your inner picture of the life in any city is supported by and reflective of the organisation and expressions that make up the built environment – that is your picture reflects your impressions of the city. The society, the community, the organisations and the built environment can be seen as systems supporting and/or hindering different behaviour. Sustainability may be fully supported by these system if such action is regarded as normal.

3 The art of making scenarios

Any vision must be valid for several different futures. One tool for exploring the future is making scenarios. These include three stages - collecting information, analysing the information and finally creating pictures of the future.

3.1 Collecting information

There are several ways of collecting information and it can be done at different levels. Depending on the time and effort spent on collecting information, a broad range of methods are available, including continuously reading and browsing media and having networks of scouts, experts, customers and other groups for future related discussions. You can also use one of several methods for interviews and public opinion surveys. Buying information and statistics from national or international data collections [3] is also a good alternative, especially if in doing so, you can track data, opinions and lifestyle changes over several decades.

In the main, information is found at three levels: 1. in the world around us, 2. in the industry and 3. in your own world. When collecting information from the surrounding world and in the industry, you should have a global perspective. When seeking changes, new inventions, shifts in opinions and the like over the last decades, you will end up with lots of information. One way to systemize this information is to divide it into different areas, like Technology, People and Institutions, to use a checklist like EPISTEL or perhaps choose some important areas from your own field. The letters in the acronym EPISTEL stand for the following subject areas: Ecological, Psychological, Institutional/Political, Social, Technological, Economical and Legal. EPISTEL is often used in analyse of effects of a larger project, such as for the bridge between Malmö and Copenhagen, but also to deal with all aspects of future study like the one on the future of Swedish newspapers - Morgondagens Dagstidning (The Tomorrow's Daily)[4].

3.2 Analysing the information

After collecting the information, the work of evaluating the information begins. By assimilating a lot of information, you often get a feel for where the future lies. That feel is always only one of several possibilities and often wrong. It is important to look at the different levels as separate systems, to do the analysis within the system and to generalise the information into events and trends of low and high effect for the system level in question. When making a scenario, you should exclude areas where your own action can alter the future, that is the your own world. While this level is clearly important, you can't do scenarios while including this level, as different scenarios would lead to different actions. You focus on trends and events of high effect for the surrounding world and your industry. On the global level, you can ask such questions as: What are the trends in IT, bio-engineering and new materials?

For a quick evaluation of the trends you will analyse two: 1. the probability of an event occurring and 2. the consequences if it occurs. Then you locate the trends in Figure 3 below.

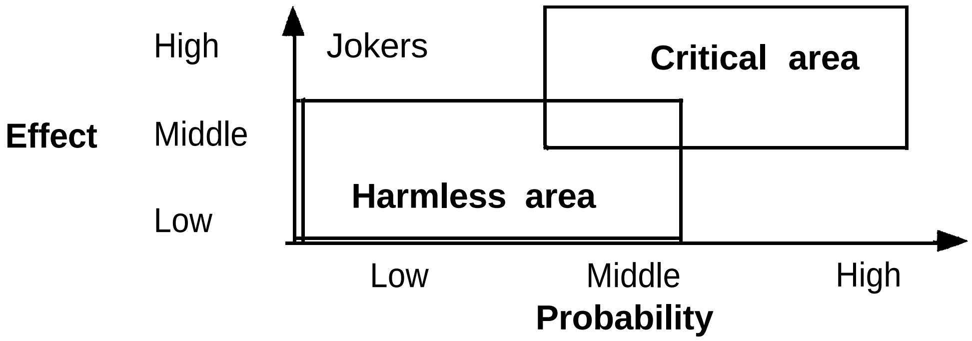

Figure 3. Effect and probability of trends. [5]

You should focus on events in the Critical area positioned in the upper right corner. Events in the upper left corner are jokers, ones with low probability but extensive consequences. These jokers should not be forgotten, even if they have low probability since their extensive consequences can make it necessary to include them in a scenario.

Next step is to evaluate each trend, asking such questions as: Where does the trend lie in a long or short term perspective? What is probability and effect of the trend? What is your knowledge about the trend, its size and reliability?

Once the evaluation is done, it is necessary to find relations between different trends and events. Some trends are only a consequences of other trends, Some trends are a driving force for other trends and some are driven by yet other trends. Some trends are neither drivers nor driven. Traditional cause and effect analysis building a tree of consequences would not be enough to describe systems of high complexity, like a society, company, organisation nor larger systems like nature and the built environment. To understand the connection between different subsystems and variables, you need other analysis methods. You can use a computer to do a multivariate analysis or use simpler methods like a cross impact-analysis, CIM [6]. With a cross impact-analysis, you can describe trends and variables in the figure below.

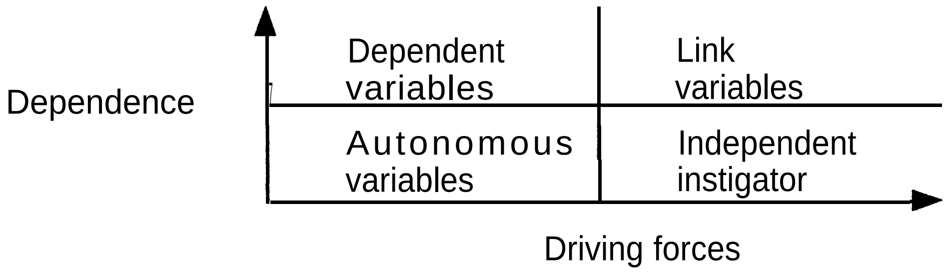

Figure 4. System of variables and trends [7]

Another, simple method is a four field-analysis [8]. You have to identify two of the most critical issues with extensive consequences. When working with scenarios for the built environment as whole, two issues which might show up at this point are: What are the trends for social and income related segregation? and What are the trends for the means of transportation? If we want to analyse these questions we can dichotomise them, describing the end points in clear contrast to each other. When we dichotomise these two questions we get four alternative scenarios:

A society with low segregation and small public transportation.
A society with high segregation and small public transportation
A society with low segregation and large public transportation
A society with high segregation and large public transportation

What can we learn more from this four field-analysis of each scenario? How probable are these scenarios? Which other trends can support such developments? What happens to other trends in the scenarios?

3.3 Creating a picture of the future
The two questions above are used to demonstrate how four field-analysis can teach us more about how different scenarios affect the built environment and sustainability. A number of other trends and issues are likely to lie on the same interest level. I have chosen 22 trends from the book Morgondagens Hem [9] (Tomorrow's Home) as examples of important trends, to whit:

New household structures: increasing number of separations, singles and smaller families.
The molecular family structure grows.
Increasing numbers of elderly.
Curing fur relatives is increasing.
Institutional child-cure a family affair?
Increased awareness of health.
Chasing new adventures.
A time fur small pleasures.
In harmony with nature.
The Real-time society.
Consumers are harder to please.
Rapid increase in the amount of information.
The pursuit of comprehensible environments.
Life-long learning.
A wurking life beyond time and space.
From steady to loose wurking cunditiuns.
Time versus money, a paradox.
The post-industrial dilemma,
New technologies enter the home.
Internet. Edutuinment - from watch to try.
On our way to equality between the sexes.

Trends supporting and driving other trends join to create a system, whose operation must be understood to be used to describe the most important scenarios vividly. What is the worst scenario and which is best scenario? What is the most probable scenario? What kind of pattern/metaphor shows the trends and scenarios? Is it ***Win or Loose,Challenge and response or Evolution versus organic growth.*** It is important to understand which pattern you are describing. For a long time, the connection between economy and environment was seen as a struggle, like in the metaphor ***Win or Loose.*** Thoughts like sustainability didn't fit the pattern, being a principle for both economic and environmental development.

4 The vision

4.1 Congruent values

4.11 Sustainability as a principle

For people to adopt a vision it needs to be congruent with their set of values. The vision must be described in the context of what is happening today. The raw material for building a vision about a future built environment is the current built environment and its inhabitants. If the built environment and people's values, or in other words their neighbourhood and their daily life, are very different as compared to other areas, share the vision with the other areas becomes problematical. You will have the same problem in sharing a vision not congruent to people's value sets in a company, organisation and society as a whole. If you regard sustainabilty as a principle, that is an accepted or professed rule of action or conduct, the key purpose of the vision is to motivate such action or conduct inherent in that principle.

The principle of sustainability is more important than sharing the same personal vision. We could share the same picture about what we don't want to happen, a global environmental collapse for instance, but my picture of my future is different from your picture of your future. What we can do is to establish areas of congruent visions in areas of congruent values.

4.12 Sustainability as a trend

A group of environmental activists have no problem understanding why they should set up a vision to support sustainability, but can companies making cars and houses have that same clear grasp of why they should share a vision supporting sustainability? Probably not for the same reasons as the environmental activists. While they would be more interested in a vision making better cars/houses and more profit, a sustainability vision is not incompatible. If you look at sustainability as a trend, that is on the trend's effects, probability and connections to other trends, you will find that it is a prime driving force with high effect on several system levels and with high occurrence probability. Ignoring such a trend will be critical at any system level when planning for the future.

4.2 The compelling vision

A vision's most important task is to be compelling, to describe a positive future. The motivation ta start the process of searching for and describing a vision can be a threat. A threat which also making you hold onto the old and secure and avoiding the forward-looking vision. The vision must be at least as attractive as the old and secure. Politicians who cannot describe their vision in terms more compelling than the old and secure must depend on old politics to be elected. Companies with the same problem are stuck with old customers.

Organisations with weakly attractive visions often have great problems. The members and employees remain tied to values, frames of reference and lifestyles which often are nut the same as those of their leaders. If you want to share the vision within the organisation, everybody must be involved in the process of creating that picture of the future. If you want to share the vision with the inhabitants, they too must be involved in the creative process.

4.3 The frames of the vision

In the process of making your picture of the future, your vision, you must remember that the vision is your tool for owning the future. Your vision is either impossible or within the framework of a possible future. Be careful not to describe a vision which requires too many changes in values in too short a period of time. Two other historic mistakes are: 1. to underestimate the changes caused by new inventions and 2. to underestimate the time these inventions need to get established on the market. When you enter today's reality you have certain momentum and direction. See Figure 5 below.

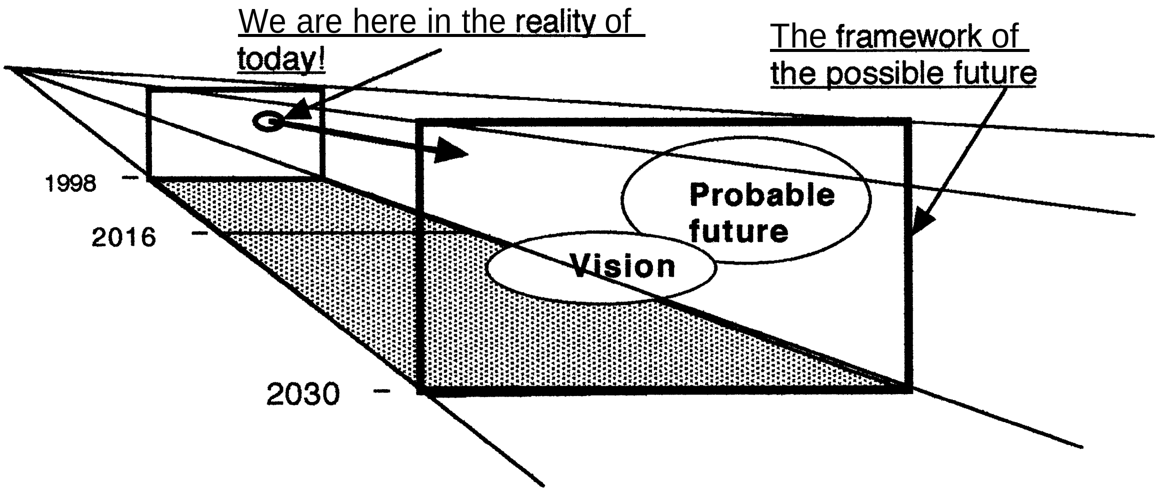

Figure 5. The connection between vision, probable future and the framework of the possible future.

The built environment will under all circumstances be here in 2030 and it will have a certain momentum and direction derived from today's reality. This momentum is the pace of change in the built environment and the direction is towards the probable future, If you want to have high probability of attaining your vision, it should be close to the probable future. If you want depart from the probable future, placing your vision as far away from it as possible, your probability of attaining your vision is much lower. Possible utopias lie close to the framework of the possible future and all mainstream planning lies within the probable future. Visions for supporting sustainability ought to lie somewhere in between mainstream and utopia. The vision should be valid for several different futures. Analyse the vision from the perspective of what the future world around us is like – 1. The Probable future scenario, 2. The best scenario, 3. The worst scenario, 4. Two unexpected scenarios. Evaluate and change your vision as needed in the light of the scenarios.

The vision should guide you into the future and inspire you to create your own future!

Designing for Sustainability:
Ideal and Practical Increments of Change

Raymond J Cole
School of Architecture; University of British Columbia, Vancouver, Canada

Abstract

The increase in discussion of life-cycle analysis and assessments has stimulated and reinforced the importance of being conscious of the future implications of design decisions. The majority of this discussion relates to the technical performance of buildings with little reference given to changing occupant needs and expectations. If technical advances in environmental performance are too extreme, or are in conflict with or compromise occupant expectations, they will ultimately prove ineffective.

This paper argues that if a primary value and role of innovative buildings is to inform and guide mainstream practice which follow in their wake, then the increment of the advances incorporated beyond mainstream practice, and their performance and acceptance through time, become critical design considerations. Case-study buildings are used to explore the way in which the performance of innovative environmental building can change through time through both deficiencies in technical performance and the actions of the building occupants as they attempt to adapt the building to suit changing needs or realign it with other time-honored expectations. To focus the discussion, environmental strategies which directly require the involvement of building occupants and which impact on their expectations are examined: moveable night-time insulation in passive solar buildings and the elimination of interior finishes.

The paper exposes practical realities which, if ignored, may ultimately temper the extent of significant environmental advancements in building design. Unless buildings can satisfy a range of use patterns, occupant expectations, provide comfort and ease of operation together with ongoing user education, and product replacement, it is unlikely that their intended performance will be sustained. This study is further evidence that innovative buildings require their designers to anticipate and account for a wider range of interpretations and performances - now and through time.

Keywords .
Innovative housing, Passive solar, Performance, User acceptance, Renovation

1. Introduction

The increase in discussion of life-cycle analysis and assessments has reinforced the importance of being conscious of the future implications of design decisions. However, Life-cycle analysis is primarily a quantitative analysis — dealing with the physical characteristics of building performance. Little, if any, reference is made to the changes in human expectations and occupant use patterns over the life of a building. Addressing the environmental agenda clearly requires significant improvements in building performance beyond current practice. But because we have yet to seriously challenge patterns of living, the primary architectural response to environmental issues has been one of providing increasingly better building envelopes and systems around fundamentally unchanged. occupant attitudes, expectations and actions. Therefore, if technical advances in environmental performance conflict with or compromise occupants expectations, they will invariably prove ineffective.

Case-studies on environmentally progressive buildings offer demonstration that environmental progress is possible, provide a measure of that progress and represent common ground for research and practice, designers and users. In fact they represent the *only* means by which we can fully understand the validity or acceptance of a particular environmental strategy. However, case studies are typically newly completed projects -the true merits or problems of which have yet to appear. Moreover, only the successes of case-study buildings are typically reported. Deficiencies, if any, are not publicly discussed, making it difficult to gain clear and complete understanding of progress.

This paper uses two case-study buildings to explore the way in which the relative performance of innovative environmental building can change through time -the *Kitsun* townhouse project, (1979) which has been monitored over a twenty year period, and a more recent project - the *Strawberry Vale Elementary School* (1996). In both cases alterations have been made to the original design, in part through deficiencies in technical performance, but more significantly through the actions of the building occupants as they attempt to adjust and adapt the building to both *time-honoured* and *changing* expectations regarding building performance and use. To further focus the discussion, the paper eaxmines two environmental strategies used in these projects which directly require the involvement of building occupants and which impact on their expectations: moveable night-time insulation and the elimination of interior finishes respectively. The paper argues that if a primary value and role of innovative building projects is to inform and guide mainstream practice which follow in their wake, then the *increment* of the advances incorporated beyond mainstream practice, and their performance and acceptance through time, become critical design considerations.

2. Moveable night-time insulation

A prominent strategy within solar housing during the 1970/80's was the use of moveable night-time insulation. As a strategy it represents the interface between user-involvement, comfort and energy performance. Experience with moveable night-time insulation at that time was showing'that moveable insulation, although an integral part of passive solar design, must be designed for fail-safe operation with careful. consideration to whether occupants are likely to use it correctly every day.

The *Kitsun* townhouse project in Vancouver, British Columbia is an eight-unit residential project. It was completed in 1978 and at the time represented the most advanced residential passive solar design in Canada. The key feature of the complex is the extensive array of south facing Trombe walls. This solar strategy was chosen primarily to provide visual and acoustic privacy given the minimal setback of the project from a major thoroughfare. The project also incorporated many state-of-the-art passive solar strategies when it was designed including Skylids on a 60° inclined 2.4 m wide by 1.2 m high skylight and insulating curtains on the 2.4 m wide by 4.8 m high poured concrete Trombe walls.

Initial monitoring of this highly publicized project concentrated primarily on its energy performance. Auxiliary energy use for space heat varied, due to differences in occupant lifestyle, from 1.5 GJ/year to 30 GJ/year for identical units [1]. However, for the design community, the remarkably low auxiliary energy use (averaging 8- 10 GJ/year) remained almost incidental to the building's aesthetic qualities. This. response resulted primarily from the stark visual contrast between the dark surfaces of the Trombe wall and the highly reflective quality of the insulating curtains, the visible deterioration and failure of the insulating curtains and the limited openings in the south wall being contrary to the large expanses of glazing typical of Vancouver housing

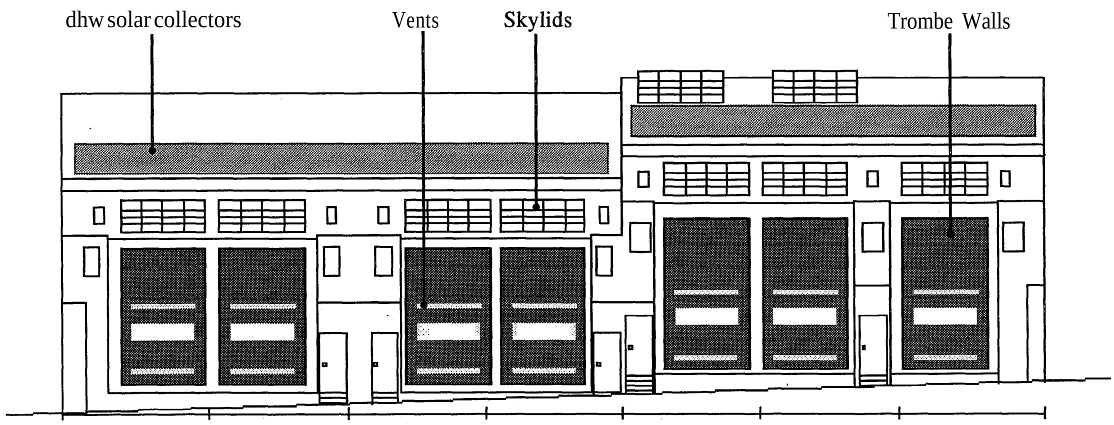

Figure *1:* South elevation of *Kitsun* townhouse project

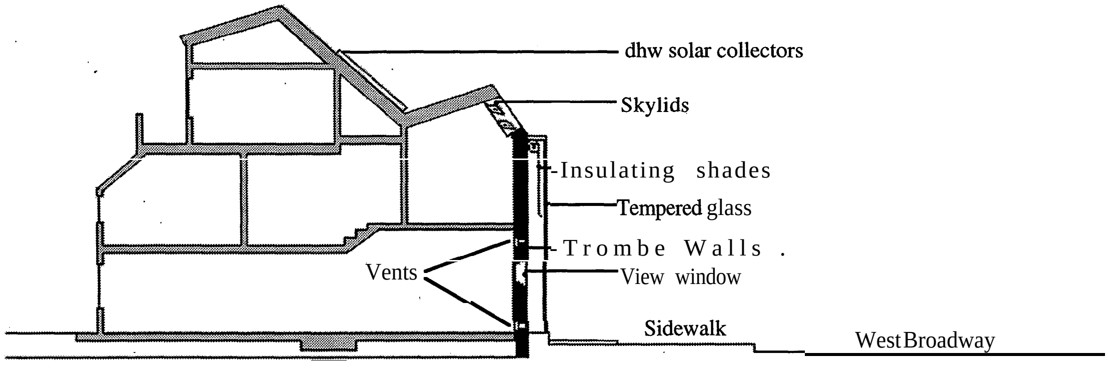

Figure 2: Section through a *Kitsun* 2-Bedroom unit (original insulating shades)

3. Mechanical failure of moveable insulation

The moveable Skylids and insulating curtains used in the *Kitsun* project served the dual role of night-time insulation and solar control against summer overheating and, as such, their effective use and performance assumes added importance.

3.1 Skylids

These initially generally functioned well after some adjustment, although they responded relatively slowly during periods of low insulation. The Skylids still generally operate and remain responsive to the day-night cycle as originally designed. However, because many of the occupants are 'unaware of their operating principle or unable to adjust and maintain them effectively, they either open and close abruptly, or very slowly They are, for the main part operated using manual over-ride.

3.2 Insulating Curtains on Trombe Wall

These had to be completely rebuilt in 1980 before they would operate under manual control with some care on the part of the building occupant. When operated automatically they would eventually crease and jam. Most occupants would operate the roll shade manually - opening it in the morning and closing it in the evening. Difficulties in providing effective edge sealing and continuity created severely compromised the overall insulating offered by the insulting curtains. Solar control, however, is only a function of covered area and less dependent solely on the loose edge condition.

In an attempt to alleviate the technical operating problems of the insulating blankets, the 2.4 m x 4.8 m high curtains were split horizontally in two of the seven units within the first year of operation (units 2 and 3). This significantly reduced the bulk created along the seams of the curtains as they were rolled up. This successful alteration would have been implemented in the remaining units, were it not for their faulty motors. Today, the only insulating blankets which remain are the two which were split in two. Due to the failure and removal of the full height insulating curtains, deciduous trees were planted in front of the Trombe walls in the late 1980s. This was primarily to soften the appearance of the complex and any potential solar shading was seen as fortuitous. These trees did not survive due to pollution and human abuse, but the strategy'has recently been repeated.

4. Human expectations/requirements

A decade ago, a glance at the south facade of the *Kitsun* project at any time-of the day or night during the summer and winter revealed varying degrees of use of the moveable systems. This was only in part due to their unsatisfactory mechanical functioning. The major differences originated from different comfort and environmental preferences of the respective occupants [2].

4.1 Limited daylight/view

An inevitable characteristic of townhouses is the potential daylight/view from only two sides. The limited south-facing window on the ground floor living/dining area in combination with an elongated floor plan compromises daylighting. Moreover; the insulating curtains further reduced daylight potential when they obscured the aperture within the Trombe wall. This conflict between two performance requirements (thermal and daylight) necessitated the positioning of the blind immediately above the aperture. In the two units retrofitted for split curtains, although the insulation properties are compromised, the residents are able to fine tune the extent and location of the curtains and can have daylight and some visual contact with the outside from the upper vent when the primary aperture is obscured.

4.2 Painting of the Trombe walls

Clearly technical and highly visible failure of the retractable insulating curtains have been a recurring problem and a key reasons for many of the subsequent changes. The outer surface of the Trombe walls were originally painted dark colour to increase the solar absorption. Each of the units were painted a different dark colour to provide a degree of individuality and variation while still maintaining a solar absorptivity greater than 0.85. These were subsequently all painted black to enhance the solar absorption In 1994 the occupants collectively agreed to have the Trombe wall repainted to lighter pastel colours. This modification has tempered the stark appearance of the project and reduced the solar loading on the mass wall during the summer, given the absence or ineffectiveness of the reflective curtains. Residents have noticed a perceptible reduction in overheating but no significant changes in their heating bills

	Insulating curtains		Trombe wall colour		
	By 1987:	**By 1997:**	**1979:**	**1987:**	**1997:**
Unit 1	Original curtains remain. Manual operation only. Rarely used during winter, closed during the summer to control excess solar gain.	Curtains removed	Black	Black,	Lt. violet
Unit 2	Original 4.8m curtains replaced with two 2.4m high segments, but otherwise generically similar. Used conscientiously for insulation and solar control.	The two curtains remain. Used judiciously for night-time insulation.	Dk. blue	Black	Lt. blue
Unit 3	As Unit 2 above.	The two curtains remain, upper not functioning. Used judiciously for insulation.	Dk. red	Black	Lt. green
Unit 4	Manual operation only. Used mainly in summer to control solar gain.	Curtains removed	Dk. blue	Black	Lt. yellow
Unit 5	Curtains broken and unused.	Curtains removed	Dk. brown	Black	Lt. yellow
Unit 6	Curtains removed.	Curtains removed	Dk. blue	Black	Lt. peach
Unit 7	Manual operation only. Rarely used during winter, closed during the summer to control excess solar gain.	Curtains removed	Black	Black	Lt. pink

Table 1: Changes made to Trombe Walls (units 1-7 from left to right in *Figure 1*)

4.3 Introduction of metal fence

Unlike other residential projects on this prominent street, the major south facade of the Kitsun project is almost at the sidewalk, bringing passers-by in close proximity to the 'front entrance' of the complex. Further, proximity to a local club creates additional noise and'periodic unsociable behaviour immediately outside. The introduction of a metal

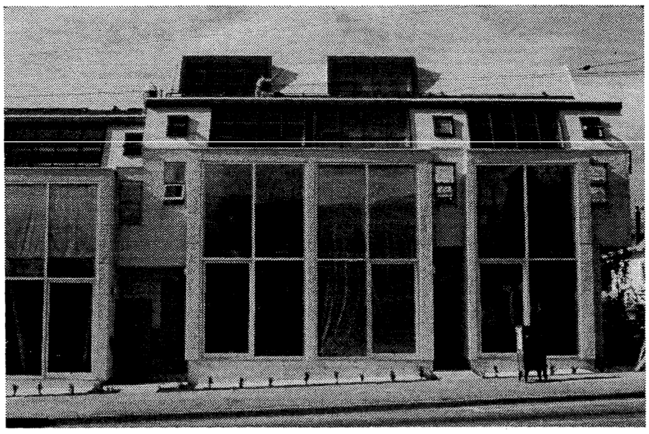

Figure 3a: ***Kitsun*** *Townhouse* project (Units 4-7) -1979

Figure 3b: ***Kitsun*** *Townhouse* project (Units 4-7) - 1987

Figure 3c: ***Kitsun*** *Townhouse* project (Units 4-7) -1997

fence in 1995 now defines a semiprivate realm for the complex and has created a new opportunity for landscaping and personalising the immediate foreground to the project through the planting of deciduous trees in a more protected environment adjacent to the solar wall and the introduction of heat resistant plants and other ornamentation behind the glazing.

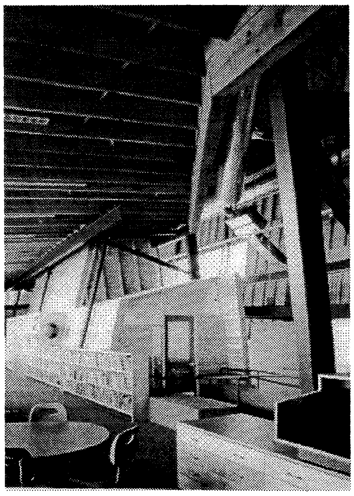
Re-examining a project like ***Kitsun*** some time after the initial period novelty and interest provides considerable insight into the longevity of passive solar strategies which rely on user acceptance and involvement. Many of the problems in this project result from the combination of the adoption of new design strategies and technologies, and the lack of foresight on. how the systems were likely to function through time and how they could be maintained effectively by their occupants. After ten years of occupancy, the performance and use of the ***Kitsun*** *Townhouse* confirmed the widely established experience of earlier passive solar houses that overly complex designs, from the standpoint of architectural and mechanical systems and the expected involvement by occupants in their operation, invariably fail. Moreover, not only should as much consideration be given to avoiding solar overheating as providing useful winter heating, but that the actual use and-interpretation of passive solar buildings will be different from the simplified energy and environmental schematics that are often used during their design After approximately two decades of occupancy, a potentially more significant change is evident. Significant modifications have been consciously made to the building's original design which are clearly contrary to its original solar emphasis, primarily as a result of changes in occupant understanding, expectation and desire to realign the appearance of the building with more conventional norms.

5. Eliminating finish materials

Many environmentally progressive buildings are attaining materials reduction through the deliberate *exclusion* of traditional interior finishing materials. This strategy represents one of the most visible and direct expressions of environmentally responsive design and one'which most directly impacts on the quality and character of interior spaces.

The *Strawberry Vale Elementary School,* Victoria BC, was completed in September 1996 [3]. All of the classrooms in this 3300 m^2 facility are oriented south toward a park and woods, and are located at grade for direct access to the outdoors. To limit the length of the school the classrooms are grouped in pods of four. .A meandering circulation spine connects the pods with the library, administration and gym.

In addition to a thoughtful consideration of a host of environmental characteristics of building materials, the amount of drywall was reduced by completely eliminated it in the main circulation spine and public areas *(Figure 4a)* and limiting its application to specific



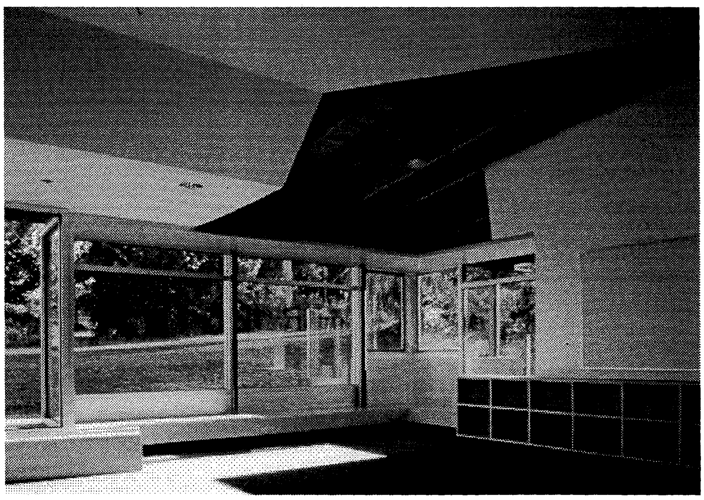


Figure 4a & b: Strawberry Vale School: Public Areas/Circulation spine and Classroom areas in the classroom spaces where it would be most effective at reflecting daylight (Figure *4b)*. This strategy was consistent with a broader architectural notion that the richness of a building derives, in part, through expressing how it was built. Similarly, finished concrete is used over extensive circulation areas and 'wet' areas to eliminate the need for additional flooring materials and attendant adhesives. Although the actual amounts of materials saved through these strategies in terms of mass or volume is modest, the visual impact is profound. It emphasises and communicates the need to be selective in the use of materials rather than unthinkingly applying anywhere and everywhere.

Although all of environmental strategies were agreed to by the client at the outset, within less than a year of opening, changes have begun to be made to the interior which again are contrary to the original design intention. The original open plan reception area has now been enclosed — and sections of the finished concrete seating along the central circulation spine have been fitted with wooden tops. Unlike the *Kitsun* project where the benefits to time have revealed the full extent of the change, it is difficult to anticipate the extent or type of modifications which may be made to the school and whether any of the exposed areas of structured will be covered for acoustic, maintenance or other reasons. Irrespectively, it points to the difference between environmental strategies which challenge and impose more directly on occupant expectation from those which remain innocuous.'

6. Conclusions

The environmental agenda will require a significant improvement in the performance of buildings beyond current practice. The acceptance of environmentally progressive buildings is premised only in part on the energy and environmental benefits they offer. This paper has focused on some of the practical realities which, if ignored, may ultimately limit the extent and rate of significant environmental advancements. Unless buildings can satisfy a range of use patterns, occupant expectations, provide comfort and ease of operation together with ongoing user education and product replacement, it is unlikely that their intended performance will be sustained. This study is further evidence that innovative buildings require their designers to anticipate and account for a wider range of interpretations and performances - now and through time. Until such time that a broad-based environmental ethic develops and when building occupants are willing to reassess priorities and expectations, and participate more actively in building operation, the increments of technical advance incorporated into buildings must be carefully evaluated and set with reference to time-honoured expectations and qualities.

Sustainable Constructions* Strategies from the Technological / Biological Perspective

A. **Cobzaru, eng.**
INCERC - National Building Research Institute, Iasi, Romania

Abstract

The demand for a massive volume of healthy homes in the last **20 years** in the world, also in Romania, together with the demand for the design and realization of healthy autonomous energy houses, appear now, towards the end of this millennium, under many contradictory sides:

- the affordable living through the **social cost** of the building integration into the urban space and in the constructions' strategies;

- the comfortable living through the imposed degrees of functional, aesthetical, high-technological qualities of the buildings;

- the healthy living through the **eco-system levels of integration,** in a healthy environment;

in an area wherein **the strategies** and **the decisions** at the institutional level are very often low or not compatible. The paper proposes an approach from the technological towards the biological perspective for the living space development seeing the constructional effort to urbanize the space not 80% dominated by the contemporary tendency to build technologically but considering the real output of the building and its long distance effect on the environment.

As conclusions we mention:

- as long as we build for **men,** the real output of the living space can not be considered just from a **technological perspective.**
- where it is possible would be extremely interesting and useful to determine the correlation existing between the accumulating degree of forces, tensions (not only the seismic ones), other effects caused by the biofactors (side B, fig. 2) and the responsive time of the society.
- the biological perspective to think the strategies for any existing or new sustainable l i v i n g space, is imperative and no longer avoidable, against the economical wall. Through the contemporary way to think and build, we may not be able to control some devastating answers like the waterfall accumulations responses, as we are today witnesses on many levels and many countries.
- the freedom to build and benefit from a sustainable living space can not be real without being conscious of the **negotiable** edge between the technological and the biological way to design and which **is the real price** of a house.

Keywords: affordable, comfortable, healthy living, future perspective

Introduction

A **healthy** house can be characterized by the promotion of occupant health, energy efficiency, resource efficiency, environmental responsibility and affordability. Its design should promote superior quality of indoor environment (air, water and lighting, as well as minimal exposure to background sound and radiation), namely comfort. To afford a comfortable living space, considering that the energy consumption is to be reduced for space heating or cooling, water heating and various appliances, is critical when it comes to adaptability to the changing needs or number of occupants. Or more, in an increased number of homes or cities! Efficient use and durability of building materials and management of construction waste is considered the keynote of the present way to design. When it comes to decide the strategies' vectors and shapes it goes all back to the **output** of the building, be it home or social administrative building.

The Building Output Concept

The ecological time we live in as a reply to the frequent environmental crises, brings up to the surface of a debate how much we could objectively ask quantitatively and qualitatively from a living space, not being redundant for the environment or for the cohabitants? The living into big urban crowd places can not be acceptable without to consider the maximum admissible and measurable redundancy! On the way how the future living would look like, there are many suggestions for new forms **of** habitat such **as** *homes in homes, terrace homes, suspended flats, total homes*. Still keeping in mind the healthy house, whatsoever the name of the new solution, the problem of any sustainable construction bring the question of the building output. For its expression, very few mention all the categories from A to E (fig.1) in an analytical relation as an usual tool to evaluate the living space's qualities. In the physical sciences somehow bound to *man (people)* activities, like building houses, urban development, population growth, etc. the observational data of the manipulated, moving environment are different up from a point than in the physical sciences let's say more inorganically bound to the environment, such as Mechanics, Astronomy, Geology, even Archeology. Therefore searching just by the technological usual means (see η_{Th}, η_{Tc}, η_{Ec}- fig. 1) to prove the efficiency of a new or existing building, wouldn't be enough.
The **output concept** comes almost from Mechanics where the loss coefficient η defined as a ratio Q_g / Q_a between the thermal, mechanical, chemical, etc. absorbed energy Q_a and the given energy Q_g, shoes the economical degree in which a machine works. Or extended to us *a system works*.
Having this side of thermodynamics, essential for biology, biosociology, bioengineering because any living body, any scale, acts as a system wherein happens permanent and complex changes of energy, we could make the appreciation of the living:
A - strictly physical, measurable, approximating the house with a thermal machine, running irreversible changes through the thermal, water, electricity, gas sources. So comes the known technical outputs, classically defined through reproducible measurements of energies flows, consumptions, fluxes, even punctual instantaneous values of temperatures, air velocities, etc. Nothing goes **technically beyond the technological limitations** of the conventional energetic analyses, even if in a complex system, as any house is appears a powerful qualitative unequivalence when in or out of the house (the strict mechanical

A. Functional output η_F

- ⇨ Continuous/ discont. functions of basic installations: water supply, gas, electr., thermal
- ⇨ Grey energy administration
- ⇨ Use of retrievable energies
- ⇨ Building location in space: - poluted or not
  - green area, etc.
- ⇨ Functionals' quality: compartments

B. Technical output η_{Th}

- ⇨ Structure's safety
- ⇨ Thermal protection
- ⇨ Acoustic protection
- ⇨ Put out fire protection
- ⇨ Anticorrosion protection

C. Technological output η_{Te}

- ⇨ Work's costs on the building site
- ⇨ Technological costs of the prefabs
- ⇨ Transport costs for the building materials

The Living Space

D. Giobal economical output η EC

- ⇨ Estimations' costs

- ⇨ Continuous / discont. collecting residues
- ⇨ The green level of the assembly
- ⇨ Natural accesses:
  - day light
  - fresh air, not conditioned
  - gardens, parcs

Fig. 1 - The global output of the building related to the environment

machine) are activating people (individuals, groups, big crowds).
So follows as necessary an other level to appreciate the living:
B - biophysical, partly unquantified, but obvious manifested through what we expressed in the fig. 1 as Functional output η_F(A) and η_{Ps}(E) Average psycho-social output.
For η_F and η_{Ps} there are not yet, like in the case of costs or consumptions, mathematical criteria or straight definitions to obtain illustrative values for the biophysic level of evaluation. Strictly mathematic, each of the outputs in the fig.1, might be interpreted as having equal or proportional **weights** (i.e. 20% or else) within the global output, but the real weight of each output type must be correlated with the physical or biophysical level from which we see it.

Evaluation Questions

At the physical level, with approximations with practical sense, we could evaluate no more than η_{Th}, η_{Te}, η_{Ec} covering according to the previous experience in the field, almost 60 % from all the aspects connected with the losses or economies of the living space. Apparently the rest of percentages left for η_F, η_{Ps} are commonly considered improved or ignored in relation with the others. Just at the biophysical level, because of the different scale and means of evaluations for the tensions, forces and accumulation effects, η_F or η_{Ps} become significant comparing to η_{Th}, η_{Te}, η_{Ec} which are no more operative further of **this level.**
We could easily conclude that the weight of the unmeasurable factors (fig. 2) in the evolution of **a sustainable built environment** is quite significant and could dominate the global cost of the building, the global output of the built space and determine responsible decisions in a preventive system. Their significance is also important to be considered in the functioning of the individuals as social elements, of the groups as environmentally integrated bodies, depending on a specific area and a time scale.
Starting from these evaluation questions and fig.1 we made a connection scheme in fig.2 to emphasize as significant for the contemporary living:

- **the measurable criteria practically** involved to evaluate the optimal functional
- **the unmeasurable by practical means criteria**, involved to appreciate objectively the optimum in living

The significance of the whole range of effects of the side B in the fig.2 is not included in any form or type of technic-economical balance. We therefore named them unmeasurable categories of effects, felled through environmental functions become stressful factors as consequence for the dysfunctions in the living system.
They become a significant counterpart in a type of balance, approached as a category of evidences between:

- Practical evaluable effects through
  - consumptions electrically, thermally, hydro, chemically, mechanically, etc. measurable
  - reproducible physical evidences through limited physical means
- Indirectly measurable effects sometimes unevaluable, coming almost from:
  - stressful conditions of living
  - unsuitable hygienical living
  - underdesigned environment coming from poor economical conditions
  - unsustainable built environment from the over polluted living conditions or over usage of often forbidden radioactive building materials

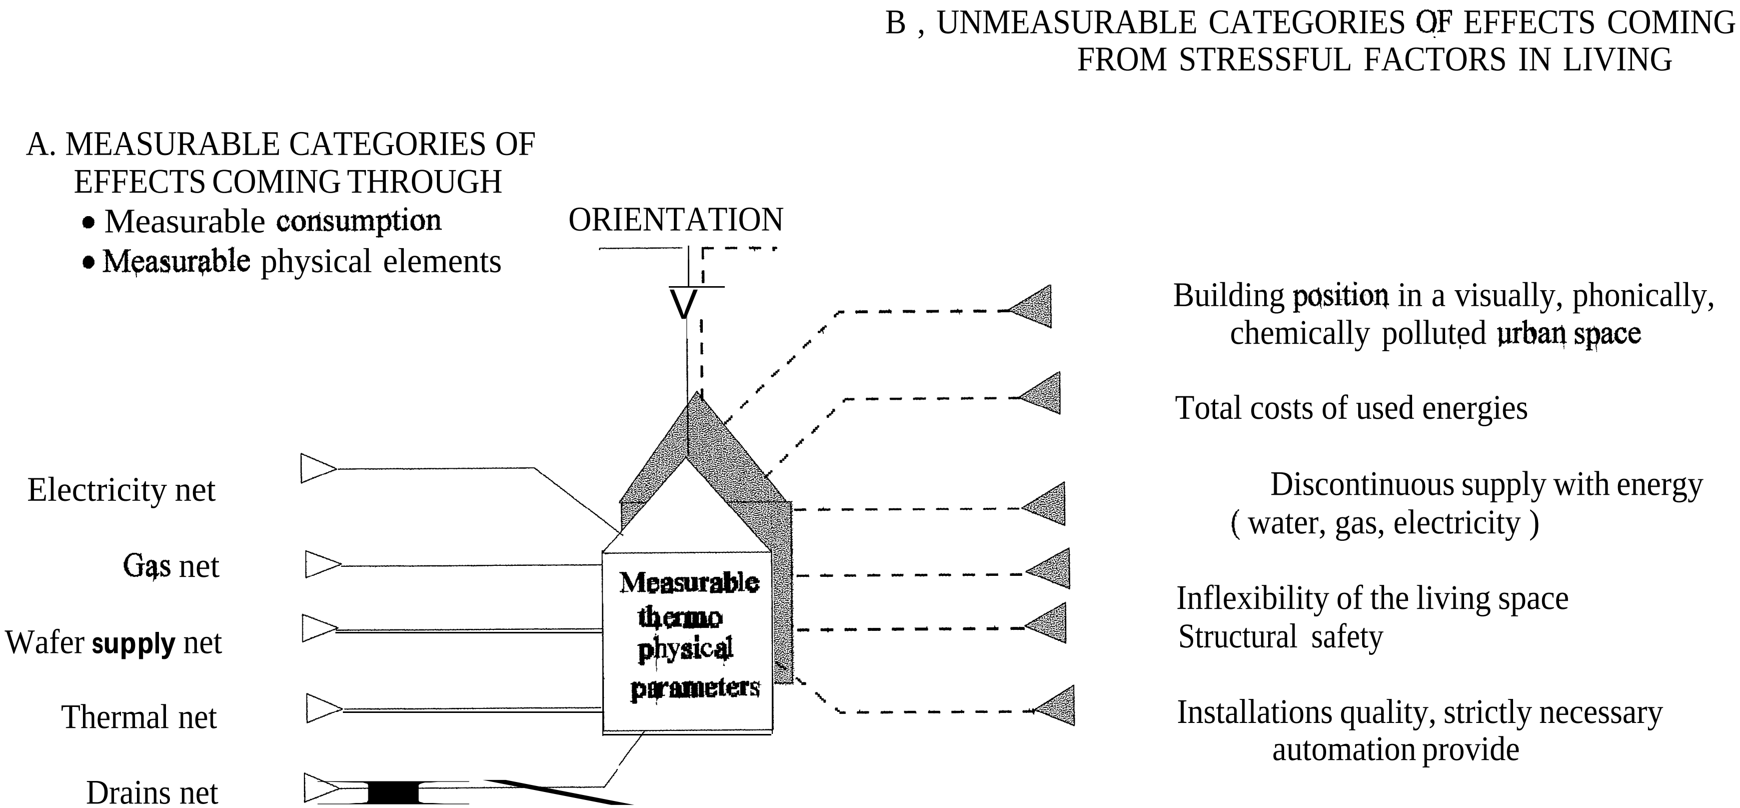

Fig. 2. New look over the measurable - unmeasurable balance
effects in the. living space

From the contemporary existent literature in the field, from some selectively chosen examples of the moments for some social disasters, appears like an evidence that we are far from understanding, analytically processing or using preventive tools of evaluation for the influences coming from the internal accumulations factors at the society level, due to its disfunction. There are unknown as in the case of the unmeasurable effects in the built environment, researches to emphasize some kind of such correlations.

Conclusions

•As long as we build for **men,** the real output of the living space can not be considered just from a **technological perspective.**

*Where it is possible, would be extremely interesting and useful to determine the correlation existing between the accumulating degree of forces, tensions (not only the seismic ones), other effects caused by the biofactors (side B, fig. 2) and the responsive temps of the society.

*The biological perspective to think the strategies for any existing or new sustainable living space, is imperative and no longer avoidable, against the economical wall.

*Through the contemporary way to think and build, we may not be able to control some devastating answers like the waterfall accumulations responses, as we are today witnesses on many levels and many countries.

•The freedom to build and benefit from a sustainable living space can not be real without being conscious of the **negotiable edge** between the technological and the biological way to design and which **is the real price** of a house.

MODELLING SUSTAINABLE COMMUNITY DEVELOPMENT IN EDINBURGH'S SOUTH EAST WEDGE

M Deakin, Building and Surveying, Napier University, Edinburgh, Scotland
J Hine, Civil and Transportation Engineering, Napier University, Edinburgh, Scotland

Abstract

Chester-ton's **(1996)** final report on the Edinburgh South East Wedge, represents the 'interim framework' for the development of a 1,400 hectare site on the edge of the City[1]. Commissioned by a consortium of public-private sector interests, including the former Regional and District Councils, enterprise agencies and respective landowners, the document provides the said 'partnership' with the strategic guidance and direction required to develop an area of land wedged between the City's South East boundary, green belt and surrounding settlements of East and Mid Lothian.

This paper aims to set out the new style of economic development and environmental planning the interim framework for the Edinburgh South East Wedge represents by looking at the conceptual model the proposal draws upon and by examining the principles of sustainable community development the plan puts in place to balance the conflicting demands of growth, expansion and conservation in the City. The paper suggests that the model of sustainable community development adopted for Edinburgh's South East Wedge is flawed in the sense it relies too much on the economic development of land and property markets and does not give sufficient attention to the ecology of environmental planning.

Keywords: economic development, environmental planning, sustainable communities.

New style planning

As an experiment in the new style of economic development and environmental planning, the framework's strategy for the 'balancing' of development, growth, expansion and conservation, proposes to adopt the principles of sustainability as a means of improving the relationship between the natural and built environment. In addressing this matter, the framework suggests the answer to this question of 'balance' and search for a form of development which reconciles the competing demands of growth, expansion and conservation, lies the distinctive urban design, layout and pattern of settlement the interim framework sets out for the growth and expansion of the City into the area of land known as Edinburgh's South East Wedge.

The conceptual model

The distinctive form of urban development it proposes is set out in the conceptual model of the South East Wedge. What the model proposes is that the design, layout and settlement pattern of the distinctive urban development in question should be based on:-

- the integration of existing urban settlements with new community developments;
- the planning of a new community development in a responsible, sustainable way;
- the development of a strong landscape framework.

Defining integration as the effective fusion of existing settlements with the new community forming part of the proposal, the report suggests the South East Wedge has the potential to create a distinctive urban character for the land in question via the formation of three distinct clusters of settlement. Three distinct settlement clusters, linked by the public transportation corridor, the framework also proposes, should be developed for such purposes. Expanding on this point, the document proposes the distinct urban character of the development should take the following form:

- the regeneration of a run down urban settlement;
- the expansion of an existing settlement;
- development of a new community.

In total, the framework anticipates that the clusters of settlements and new community will provide about 5,000 additional residential units and an expanded resident population of approximately 20,000. Reflecting further on the question of urban form, the document states: ".... the urban design challenge will be to create a high quality living and working environment. The [regenerated, expanded and new community] neighbourhoods should be conceived as essentially **urban** in character and designed on the following principles of sustainable development." (p.5). The principles in question are those of settlements and communities exhibiting:

- a spatially compact urban form;
- a high density of population;
- a balance of uses, economic and social structures;
- energy conscious public transportation;
- designs to provide a high quality living and working environment in identifiable neighbourhood units;
- a strong degree of financial viability in the short, medium and long term horizon.

The principles in question

The question of a spatially compact urban form can be read in a number of ways. First, as a development and environmental strategy on a sub-regional scale, the framework can be seen to concentrate the pressure for growth and expansion in one part of the city and conserve the environment of others. Secondly, on the district scale, it can be seen to concentrate pressure for growth and expansion in a collection of settlements, clustering them together in a form that avoids coalescence and conserves the environment (see figure 1).

It is this clustering of growth and expansion into existing settlements and new communities, while conserving the environment, that requires higher population densities. The balance of uses: residential, commercial, infrastructural and communal, are required for the communities to form four identifiable neighbourhood units. The question of energy conscious settlements rests with the high level public transportation network proposed for the development. This transportation network includes a number of measures such as a public transport corridor; bus priority proposals; park and ride provision and traffic calming. It also proposes that some of the neighbourhood units should be car free and residents ought to be within easy walking distance of public transport facilities. Together this combination of design factors are seen to provide for a high quality living and working environment, further augmented by the fact that the principles of sustainability underlying the development of the South East Wedge are to be strengthened by the layout and settlement of both communities and neighbourhood units in accordance with a 'strong landscape framework'.

The matter of financial viability tackles the particular difficulties the site confronts in terms of geo-technic problems associated with the extensive mining activities previously carried out in the area. Given the 'abnormal' site preparation costs, high infrastructure and communal content, the framework sets out what the strategy for the development, growth, expansion and conservation of the environment yield in the form of land receipts. As the viability study points out, the assumptions of the exercise and calculations show a net welfare improvement (in the form of an internal rate of return) of 8% p.a. over an inter-generational development period of 20 years.

Sustainable community development

It is evident that the distinct urban form proposed for the South East Wedge follows the commitment to sustainable development found in *The Bruntland Report* and in the EU's *Green Paper on the Urban Environment* [2-3]. The latter, having a

particular commitment to the development of sustainable urban forms in terms of the compact city, with higher densities, balanced uses and energy conscious forms of public transport, reducing the need to travel and providing high quality living and working environments for communities with identifiable neighbourhood units. It is a form of commitment also reflected in the UK Government's *Common Inheritance,* the EU's *Towards Sustainability* and reiterated in the *Rio Earth Summit* [4-6]. Commitments to compactness, high densities, mixed uses and energy conscious public transportation most recently promoted in the UK Government's *Sustainable Development Strategy, Planning Policy, Guidance Notes,* (PPGN's) Nos. **12** and **13** [7-9]. Arguments on urban form, design, layout and settlement, also well rehearsed by Elkin, McLaren and Hillman (1991), Breheny (1992a; 1992b) Owen (1992), Nijkamp and Parrels (1994) Haughton and Hunter (1994) [10-15]. Arguments that Rydin (1997) points out, while well rehearsed are ultimately contestable, representing a discourse within the policy community and networks of the UK that is difficult to either draw upon or operationalise as a means to measure the exact degree of commitment which exists to the development of sustainable communities [16].

Sustainable community development in Edinburgh

While contestable, what is clear is that strong evidence does exist to show the policy community in Edinburgh draws heavily on *This Common Inheritance,* the *Sustainable Development Strategy* and *PPGN's* 13 *and* 14 and form networks of communication which operationalise such instruments by guiding and directing the growth, expansion and conservation in question through a consultative and partnership approach to urban design, layout and settlement [17]. It is perhaps, however, the matter of what form the planning guidance and direction takes within the policy community and networks of Edinburgh's South East Wedge that represents the question in hand and matter which requires particular attention. For while the interim framework is put forward to represent a radical experiment in the shift away from property market-led development and towards forms of environmental planning under the policy commitment to sustainability, it is evident a number of the conventions underlying the former type of development can still be found in environmentalism of the latter. This is because, far from representing a break with convention, it is evident that many of the neo-liberal traditions underlying the pro-growth, expansion-minded development rhetoric and enterprise culture of market economies, also survives the transition towards environmental planning - albeit under the more inclusive rubric of economic development, growth, expansion and environmental conservation [18].

The way in which the framework for the South East Wedge manages to stick with convention, rather than make a radical break with tradition is instructive and deserves further attention. This is because in focusing attention on the continuation of past trends, conventions and extension of traditions built up over the past decade, it has the effect of highlighting questions about the communicative and technical qualities of enterprise culture founded upon the civic virtues, consultation, partnership and competition of pro-growth, expansion-minded economic development, while drawing attention away from matters concerning the transition to appropriate forms of environmental planning strategy and conservation [19-20]. The tactic the framework adopts in this aim is simple. What is does is to focus attention on the one common denominator in the 'economic development cum environmental planning strategy' equation, that of the 'market' and questions about the use which land should be put in order for the economic development and environmental planning strategy to meet the needs of growth, expansion and conservation. What this does is reduce the question of economic development and environmental planning strategy surrounding the matter of distinctive urban forms, design, layout and settlement patterns to concerns about the use of land in sustainable communities. To be more precise, to the economic development and environmental planning of land as the strategic means to balance growth, expansion and conservation in the production of distinct urban forms, layouts and settlements for sustainable communities.

As a form of land management, the economic development and environmental planning strategy the framework adopts for this purpose also has to be recognised as having its rationale firmly rooted in the market. For nowhere in the framework do the proposals for the development of the South East Wedge manage to transcend the market or its mechanisms for the allocation of uses to land. This is because in line with the conventions and traditions built up over the past decade, the main point of concern lies not so much with the communicative and technical demands of an economic development cum environmental planning strategy, as with the accountability, value for money, economy, efficiency and effectiveness disclosures needed to fund expenditures on the servicing of infrastructures with abnormal costs under the growth, expansion and conservation measures laid down for the South East Wedge [21-25].

Of perhaps even greater concern is the fact that in restricting the economic development and environmental strategy to the market, the framework also reduces the form of environmental economics it takes to a question over the exchange of land and as a consequence is silent on the question of built forms. This has the unfortunate effect of concentrating attention on the release of development value from the economics of the environmental planning strategy and 'gain' resulting from the allocation of land into a distinct urban form, layout and settlement pattern, rather than the impact resulting from the engineering and construction of the buildings forming the sustainable communities in question, Nowhere does the examination transcend the market for land, or matter of planning gain. Neither does it manage to address questions about built forms, attempt to 'green' economic development, or make planning 'environmentally friendly' by either 'valuing the environment', or 'costing the earth' through impact assessments based on a full cost pricing mechanism, hedonic, or contingency style appraisal [26-27].

Some comments on the South East Wedge

If it can be accepted that the interim framework takes a sectoral rather than holistic approach to the development of the South East Wedge - if only for the fact its urban character centres on land uses as opposed to the built, let alone natural environment - it is necessary to identify the reasons for this so a more meaningful search for sustainable communities can be undertaken. The following discussion will do this by making a number of comments on the development of the South East Wedge:

- first of all, it has to be recognised the problems do not lie in the confusion over the meaning of sustainability in terms of either its economic or environmental components [28-29] but in how it is drawn upon and operated as a tool of economic development, growth, expansion and environmental conservation. The problem lies in the fact it reduces the issue to a question of land management under market exchange, rather than appropriate form of economic development and environmental planning strategy for land and buildings.
- the effect of this is to leave the economic and environmental relationship between the distinct urban form, clustering, identifiable communities, neighbourhood units and coalescence restrictions of the framework unclear. The economic and environmental nature of the relationship between spatially compact urban forms, separate communities and neighbourhoods needs further clarification. At present it cuts across what are accepted to represent alternative models of highly concentrated compact, or decentred and dispersed forms of communities [32-33]. As it is, the image of such urban forms goes back to the early modern reformers such as Howard, Geddes and Abercrombie, how compatible these are with the economic development and environmental planning of the contemporary era is not evident and needs to be clarified if further confusion is to be avoided.
- if the exact nature of the said relationships are to be clarified, it is evident that it will be necessary to get behind the 'green gloss' of the 'economically efficient' and 'environmentally friendly' development images of the framework and inject a much stronger ecological dimension into the analysis. Like, for example, that which exists in the debate on 'carrying capacity' [33-34]. At present and contrary to what is proposed, it is the economics of land and property market development, rather than the ecology of environmental planning that lies at the centre of the framework. What the framework needs to recognise is that the two exist independent of each other and the question is whether the latter has the capacity to carry the former and not the other way around! Asking this question opens up a much neglected issue of the framework - that of environmental impact assessment as a development planning tool, be it to do with the effects of the urban form, density, use, transport or any other such matter.
- at present the framework is not only too far removed from the ecology of environmental planning for any credible form of impact assessment, but equally too isolated from the urban and regional structure of the city the communities and neighbourhood units in question form part of. This is particularly noticeable in the matter of transportation, for while the framework raises a number of questions about impact of transport on the South East Wedge and City as a whole, it focuses on the former and excludes the latter. At present there is little evidence available to suggest that a City-wide assessment of the impact which the development of the required transportation networks will have upon Edinburgh exists, for while the plan says it 'hopes' the impact will stay within projected levels, it also goes on to say may not.

- it is also clear that the discounting mechanism the framework draws upon for the appraisal of development land is too simplistic in the manner it echoes the logic of Alonso (1967) and Denman (1972) [35-36]. In its current form it fails to give due recognition to the uncertainty and risk which underlies the development, is deterministic as opposed to probabilistic and as a consequence is not duly sensitive to the contingencies it faces [37-38]. The fact it also reduces the appraisal to a measurement of receipts from land sales means that it only captures about 20-30% of the capital expenditure in question and little, if any of the subsequent revenue commitments. Perhaps of greater significance though is the fact that such an appraisal restricts the measurement of income to capital receipts from land sales, relative to expenditure on the servicing sites, rather than capital costs and revenues from the engineering and construction of built structures forming the bulk of the development. In effectively negating the possibility of adopting 'net annual return' models for the development of land and buildings, it undermines the ability to not only measure the rate of return on capital investment from the economic development in question, but makes it virtually impossible to measure the ecology of the environment it also plans to produce in any meaningful way [39-40].

Summary

From this brief examination of the framework for the South East Wedge of Edinburgh, it is evident that as an experiment in the new post-l 990 style of plan-led economic development and environmental planning strategy, much of the growth, expansion and conservation, still leaves the balancing of the relationship between the natural and built environment to the market. If heavy reliance on the plan as an instrument of strategic guidance and direction means that a great deal of the urban form, design, layout and settlement proposed in the name of sustainable development is left to the economics of the land and property market and fails to penetrate the ecology of the environment, it has to be recognised the consensus surrounding the framework's claim to create sustainable communities with neighbourhood units, will begin to come under pressure.

Validation of multilateral building product design by the QFD method

K. Sedlbauer, A. Wichtler and N. König
Fraunhofer Institute for Building Physics, Holzkirchen and Stuttgart, Germany
(Director: Prof. Dr. Eng. habil., Dr. H.c. mult., Dr. E.h. mult. Karl Gertis)

Abstract
Building industries have developed highly specific materials and components to fulfil1 the CO2 requirements. A lot of work has been done on the optimization of building components with regard to the reduction of the energy loss by heat transmission. But in many cases this did not mean an integrated overall improvement in many properties for example such as insulation against sound and damp or the mechanical solidity and stability as required by the Building Products Act. The need for an integrated development of products in the construction sector can be deduced from this. Such an opportunity for integrated product development, taking account of all aspects right down to marketing, is provided by the method known as Quality Function Deployment (QFD). QFD is a quality-oriented, continuous planning method for products which take customers' wishes into account, specifying product development right down to individual details and influencing the implementation of the processes and the materials necessary for production. The procedure consists of a series of planning steps each of which is based on the previous one and which can be subdivided into four development phases. This QFD method and an evaluation is presented using the example of a novel roof structure. The procedure in planning the attachment of an insulation element to a substructure of cellular concrete is illustrated. In addition, both the possibilities and advantages offered by QFD are explained and the problems which may arise from non-methodical product development are shown.

Keywords: Building components, product development, planning method, Quality Function Deployment, description, evaluation

l Objective

To reduce CO, emissions from building heating, the new version of the Thermal Insulation Regulations came into force on 1 January 1995. An increasing amount of work has thus been done over the past few years on the optimization of building components with the regard to the reduction of transmitted heat loss. In many cases this did not mean an integrated overall improvement in properties, as the implementation of measures to increase thermal insulation, for instance, often lead to the neglect of other building-component properties such as insulation against sound and damp, not to mention the mechanical solidity and stability as required by the Building Products Act' [1]. In addition, an investigation carried out by the Fraunhofer Institute for Building Physics in collaboration with the Fraunhofer Institute for Production Technology and Automation [2] on the problems involved in the introduction of new and innovative building products from the point of view of small to medium-sized companies showed that difficulties regarding production technology or implementation which should really have been taken into account at the planning stage only become evident when the products are introduced onto the market. The need for an integrated development of products in the construction sector can be deducted from this. Such an opportunity for integrated product development, taking account of all aspects right down to marketing, is provided by the method known as Quality Function Deployment (QFD).

2 Approaching the solution with QFD

The QFD method originates from the mechanical engineering sector, where it has been successfully employed since the 1997s. QFD is a quality-oriented, continuous planning method for products which take customers' wishes into account, specifying product development right down to individual details and influencing the implementation of the processes and the materials necessary for production. ,The aim is to develop products with precisely the quality approximating most closely the customer's expectations and needs. On the other hand, collaboration and communication of all those involved in the development and production process means that development can be carried out very efficiently and attributably. The QFD procedure is described in detail in [2],[3] and consists of a series of planning steps each of which is based on the previous one and which can be subdivided into four development phases. Fig. 1 shows the method's sequence plan. At each of the individual steps the aim (What?) and the appropriate implementation (How?) are in each case interrelated to each other, the implementation (How?) automatically becoming the aim (What?) of the following step.

QFD thus enables customers' wishes for instance, to be sounded out already at the planning phase of future building-component developments and then translated into concrete technical requirements which then influence the entire product development. The QFD method has been applied by the IBP to building-specific requirements and actually applied in several cases (including [4]) in order to create one possibility for successfully implementing development tasks for building products.

3 QFD as exemplified by the attachment of roof insulation

The QFD method is to be presented as exemplified in a novel roof structure, and the procedure in planning the attachment of an insulation element to a substructure of cellular concrete illustrated in an abbreviated but nevertheless clearly understandable fashion. In addition, both the possibilities and advantages offered by QFD are to be explained and the problem which may arise from non-methodical product development are to be shown.

In the example mentioned, the following sometimes contradictory customer's wishes or requirements were taken into account:

- Thermal insulation (e.g. thermal resistance)
- Recyclability (e.g. separability of the insulation elements from the concrete)
- Erection costs (e.g. time needed for fitting) and
- Costs of materials

Tables 1 to 3 show, in a rudimentary way, the QFD procedure in the example in the example mentioned, and will be explained more closely during the talk: at the outset it is necessary to collate the customer's various wishes and to weight them (cf. Table 1). Table 2 shows the most important building-physics requirements for roof structures, such as thermal insulation in winter and summer, climate-related moisture insulation etc.. These are related to the customer's wishes in order to support, in the form of the resulting catalogue of requirements, the selection of various alternative construction possibilities, as shown in Table 3. A concluding evaluation in Fig. 2 is intended to present the influence of various weightings.

If a methodical product development is dispensed with, or if an error is made regarding the evaluation of the connections or the weighting at the start of the implementation of the QFD method, or if the customer's wishes are incorrectly recorded, this may lead to an erroneous decision and a faulty product which does not correspond to the requirements. This is demonstrated by the definition of two different weightings, namely:

- without erection costs
- with erection costs (high weighting)

The result is two completely different construction variants. From this fact, and from the example of successful implementation, verification of the method can be deduced.

4 Evaluation of the QFD method

An evaluation of the QFD method in the above-mentioned example shows several advantages and disadvantages. Basically, QFD is a procedure for technical experts, i.e. the method only leads to the desired success if applied in wellfounded cooperation with the customer with regard to weighting, connections and specification. The formulation of the mutual connections between the requirements and the construction variants should thus only be carried out by experts.

Sustainability Through Integration

P. Barrett, M. Sexton, M. Curado
Research Centre for the Built and Human Environment, University of Salford, UK

Abstract

To move towards sustainability in the built environment, environmental issues must become an integral part of the management systems of the organisation involved.

Taking action is one thing, moving in the appropriate long term direction is another. Without a clear strategic view of the relationship between construction activity, the built environment and society's goal it is difficult to focus action in a beneficial direction.

This paper puts forward a view as to how organisations' quality, health and safety and environmental management systems can be integrated, so that environmental issues do not remain on the barren periphery of organisational action.

The second part of the paper outlines a strategic view on the nesting of the parts set out above, drawing some conclusions for effective action in the future.

Keywords: Environmental Management, Integration, Improvement, Strategy

1. Introduction

Construction firms are increasingly faced with sustainable development-based requirements which are influencing many areas of their activities: ranging from proactive environmentally conscious design and construction, through to green marketing and asset portfolio management. These requirements are being generated by a diverse range of stakeholders who have an interest in firms' overall environmental performance: be it the growing public alarm about environmental depletion and degradation, insurance companies concerns over future liabilities centred on environmentally-hazardous land and building materials, or the emergence of green consumerism (for example, see [1]).

Environmental considerations are demanding enough for firms to manage – but they are coming on top of an existing proliferation of quality and health and safety issues. The question facing firms is whether to manage each of these requirement areas separately or to integrate and manage them as a single, cohesive system. It is argued that if sustainability (as well as quality and health and safety) considerations are to be truly promoted by firms, effort needs to be made to integrate environmental systems with other systems, and to align them with strategic direction.

It is proposed that integrated, developmental management systems is a useful means of addressing these issues. The paper is structured as follows. First, the prevailing responses to environmental, quality and health and safety requirements will be summarised. Second, the potentially adverse implications of these responses are articulated. Third, it is argued that an integrated, developmental system view is a useful way forward. Finally, a 'supple systems' approach is offered as means of operationalising this view in firms in a practical, meaningful way.

2. Prevailing responses

Corporate responses to environmental requirements come on top of existing efforts to actively manage quality and health and safety requirements. In a review of current mechanisms to manage these three issues Barrett & Sexton [1], concluded that:

- Quality requirements tend to be client-driven and are being addressed through the promotion of service or product consistency, rather than trying to cultivate continuous improvements.
- Health and safety requirements are predominantly legislation driven and are historically accommodated within firms through mechanistic systems, rather than culture-based systems which can integrate other, non legislation based, requirements.
- Environmental requirements are stakeholder-driven, a dimension which requires firms to create multiple perspective goals: a skill which many firms are failing to get to grips with.

Considering this apparently insurmountable mish-mash of requirement characteristics and organisational responses, it is temptingly easy to suggest that firms are doomed to be saddled with expensive and adversely fragmented management systems.

3. Implications for firms

The prevailing, fragmented systems have both effectiveness and efficiency implications. Bass ***et al.*** [2], for example, argue that such fragmented approaches encourage the following inefficiencies: actions and decisions being made in isolation (thus making them sub-optimal); employees being overloaded with information, and even with conflicting instruction which make open the firm up to risk; and bureaucracy.

In contrast, Barrett & Sexton [3] stress the risk of separate systems not being effective in two respects: lack of systems' alignment to overall strategic direction (shown in Figure 1 below), and lack of systems' appropriateness to engage and manage operational reality.

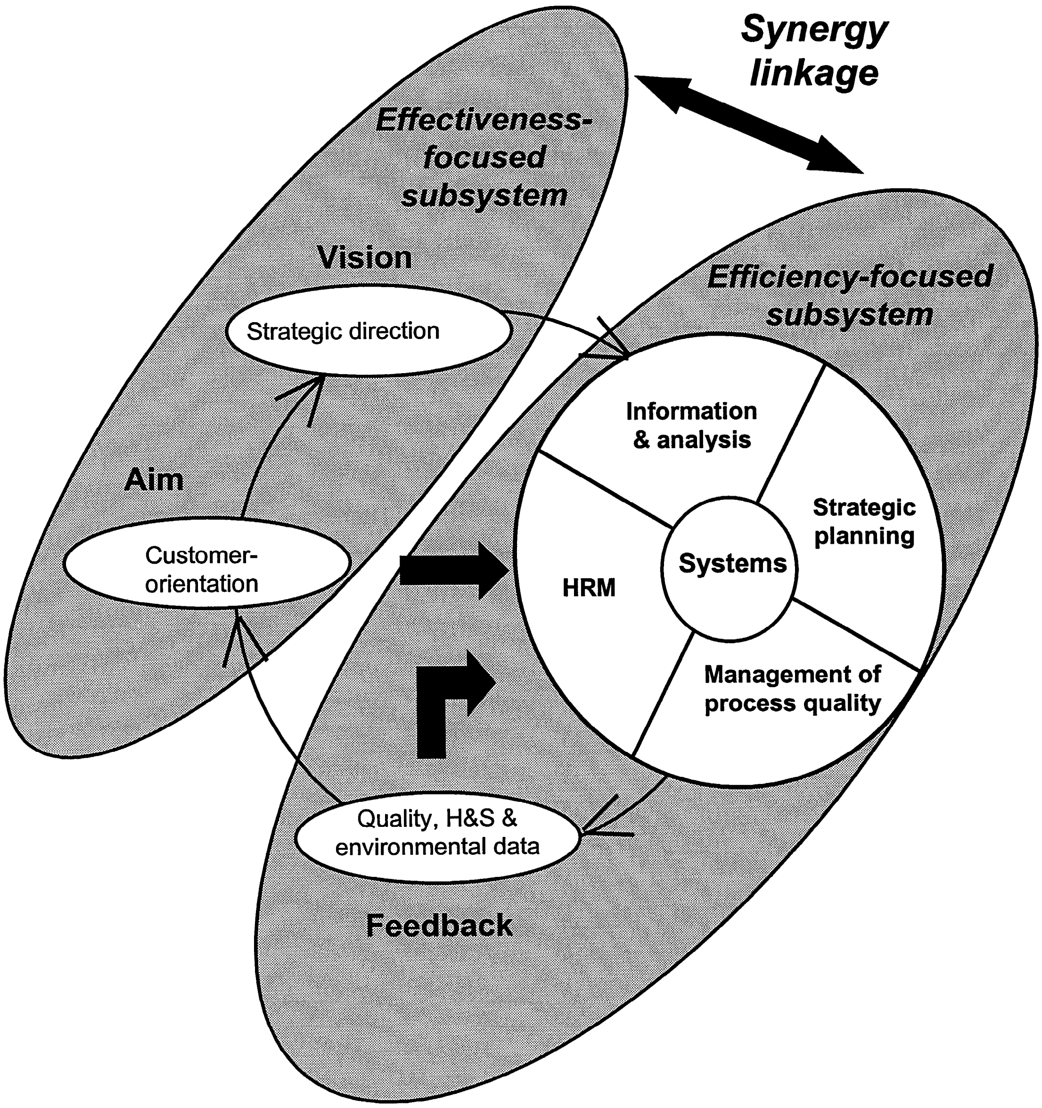

Figure 1: Aligning systems with stakeholder requirements and corporate focus

This leads to the central question in this paper: how can a firm enhance its environmental performance while also efficiently addressing the issues of quality and health and safety?

4. An integrated, developmental way forward

It can be seen that the complexity confronting firms provides a huge challenge and that the current approaches, or more recent developments, all carry problems.

The following section endeavours to effectively and efficiently 'nest' the management of environment, quality and health and safety requirements within an approach which focuses on the *improvement cycle* within firms. Thus, it can complement steady-state quality management / assurance, or be a viable option in the absence of such activity. It addresses an area where systems can contribute - the hinterland between individual action and corporate strategy - but does not pretend to address the whole of management activity.

It will be seen that the emphasis on key measures of tangible achievement fits well with the health and safety approach, at least as it appears in theory. In terms of quality there is increasing pressure to achieve improvements as well as consistency. In the environmental field this translates into an approach which allows incremental progress to be made toward meaningful action encompassing stakeholders' views.

It is suggested that the key to achieving improved organisation responses to a range of business requirements is to introduce balanced feedback mechanisms so that construction firms actually learn from occasions where it could have done better or from opportunities / ideas from other sources. This learning process is afforded by firms creating the capacity to scan, sense and monitor significant aspects of their organisational and business environments, the ability to link the resultant information to other information concerning the operating norms which direct activities, the ability to detect deviations from these norms; and the ability to initiate corrective action when deviations are detected. Furthermore, the feedback loops should encourage the capacity of the organisation to progressively improve through continuously learning, unlearning and relearning; rather than be geared towards the (eventually stagnating) maintenance of the prevailing system.

In simple terms, the construction firm collects positive feedback externally, as well as internally, then analyses the information and integrates it back into future service provision in order to improve performance levels. It should be stressed that the process is iterative and thus encourages continuous improvement, bit it must be strategically focused to avoid segmentation.

Further, the concepts of situational leadership introduced by Hersey *et al.* [4] might be useful in broadening this idea. These authors define the readiness of an individual or a group as a function of both ability and willingness, and argue that different management styles are appropriate to different levels of readiness.

The style depends on varying the levels of task and relationship components of leadership. Therefore it seems logical to expect the need for a stronger procedural approach to the implementation of environmental management in organisations that present lower levels of readiness, while for higher levels of readiness a more behavioural approach may prove itself more suited.

Based on this sort of thinking and aiming for systems which are client-responsive and facilitate a continuing cycle of improvements, an approach has been developed, through debate and observation, which endeavours to meet these criteria. The approach has been styled "supple systems" and is discussed next.

5. Supple systems

The supple system approach originated from the quality management domain (Barrett, [5]), but can be fruitfully enlarged and refocused towards the continuous improvement of how organisations address requirements generated from the business environment. The key features of supple systems are given in Table 1.

There is not space here to describe the approach in detail (see Barrett & Sexton, [6]), however, in summary, the approach advocates that a strong, but flexible *audit* system is developed which ensures that improvements in the quality of the service are being achieved. The audit system identifies sources of feedback, assesses if action is required, and at what level, prioritises between alternatives, allocates responsibility, checks later that action was taken, tries to objectively assess the impact of the actions and finally feeds these findings back to those involved.

In addition, action is required to be taken simultaneously on all of these fronts if construction firms are to be galvanised into enhancing their level of performance (see Barrett, [7], Barrett *et al.*, [S]). Firms need to create an environment in which people know what needs to be done to better support the core business. This is achieved through the *direction* provided at the strategic level which aligns systems with the core business strategy and with each other; by operationalising this vision through 'supple' systems which provides *information* about the level of performance on its full range of activities; and finally by underpinning these mechanisms by creating and supporting learning individuals and groups within an organisational context which encourages them to actively overcome problems and spot opportunities for doing things in better ways through *innovation.*

The objective, therefore, is to know what needs to be done, to know how to mesh individual actions to greatest effect and to have people involved who, once they know what is needed, are capable of, and motivated to produce, innovative solutions. The improved level of performance is the product of innovations, at all levels of the firm, each orientated towards clearly stated strategic goals by integrative supple systems. The end result of this enhanced dynamism is the creation of a continuously learning and innovating management systems that meaningfully contributes to organisational strategy formulation. The view presented here can be summarised as shown in Figure 2.

Although ultimately all of the above factors need to be working in unison to create optimum performance it is more realistic to think in terms of a sequential development. It can be argued that the feedback information is the first place to start as this will inform strategy formulation and begin to create a better informed customer orientation amongst staff. If, for a given organisation, say, a strategy already exists then this can be the springboard for the other areas instead. The particular order is not critical and is contingent upon the given organisation.

Table 1 - Key features of supple systems

Symbol	Feature	Description
	Objective-nested	The systems are aligned to, and positively support, appropriate strategic organisational obj ectives. Systems should not be developed within an operational/technical vacuum.
	Client / Stakeholder orientated	The systems are tested against stakeholder, and especially customer requirements, by actively seeking feedback through both hard and soft data.
	Minimalist / Holistic	"As much as you must, as little as you may", that is, not having systems for their own sake, but rather targeting high risk / gain areas. Better to have made some progress on all important fronts than to have patchy provision.
	Loose-jointed	The systems operate at an audit level: clarifying objectives, checking performance and integrating efforts. At an operational level different styles and approaches can be accommodated, especially when they have proved themselves over time.
	Evolutionary	Allow incremental and continuing progress to be made from whatever base.
	Symbiotic with social systems	Build on the norms and culture of the organisation, for instance allowing self-control or group pressure to operate where appropriate.

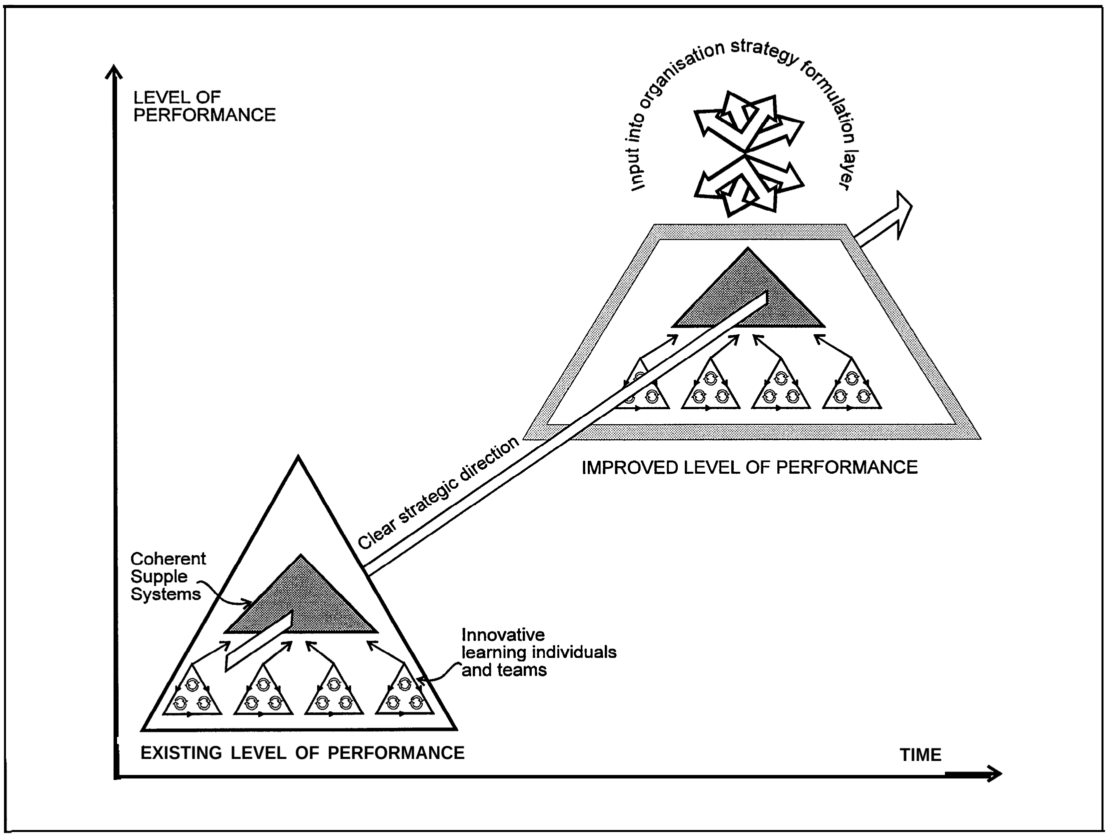

Figure 2 - Improving performance through vision and integration

6 Forces for and against integration

The level of integration of management systems seems to vary a lot along the life cycle of organisations. Small organisations tend to have a high degree of integration, accompanied by a low level of formality.

As organisations grow usually management systems grow more formal at the cost of integration. This movement is usually followed by an effort to recuperate the integration lost along the process. Different internal and business contexts may justify distinct choices regarding the degrees of integration and formality.

Multiple factors affect the degree of integration of management systems. Satisfying clients and other stakeholders should create a drive towards integration. Regulations and legislation will push towards highly formal systems, whilst costs will point towards the opposite direction.

The fact that the construction industry usually works with individual projects may play against integration, due to differing requirements.

The will of some organisations to show high profile initiatives to please specific lobbying groups may also play against integration, since there is a wish o showing neatly defined systems.

Low integration may also be fostered by lack of willingness, particularly due to the particular culture of the organisation, where an insular worldview may predominate.

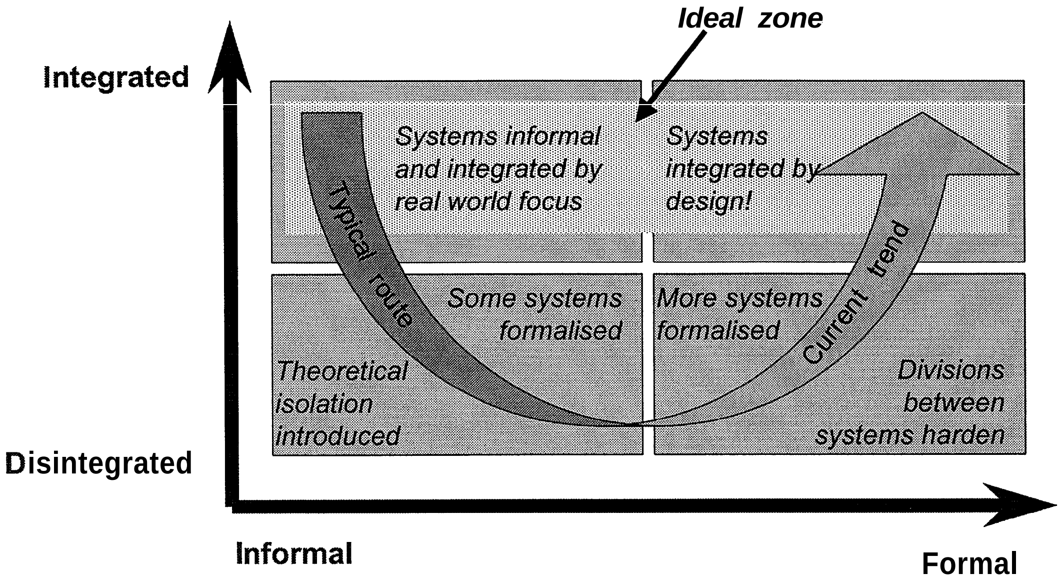

Figure 3 – Co-ordinating map

It is common to find environmental management system defined along the lines of *an organisation 's formal structure encompassing procedures, practices, resources and processes, that implements environmental management* (Griffith, [9]). We advocate that formality is not central to the definition.

Figure 3 is an attempt to summarise the current situation and propose an ideal approach. It seems reasonable to suggest a dimension running from informal to formal. There is certainly a lot of discussion about integration and so this implies the presence of its converse, namely disintegration. These two dimensions form the axes of the above diagram and allow the present situation to be illustrated very clearly.

Many firms have moved to create discrete systems, whether for quality, health and safety or environmental issues and have operationalised this in terms of formal systems. In doing so a degree of disintegration is achieved alongside the more focused management of the issue being addressed. This, then, is the "typical route" that has been taken. As more discrete systems are added the problems worsen leading to the emerging "current trend" which is for companies to seek to integrate those systems.

Arguably the response of, say, a small organisation could be effectively integrated by virtue of the fact that, although informal the firm addresses the various demands in an integrated way because that is the way they arrive as part of their workload. This could be just as appropriate as a very formal, but tightly integrated approach that might fit typically with the needs of a larger company. Thus, taking formality as a variable that is predominantly driven by factors such as size, it is suggested that there is an "ideal zone" where the response is integrated, but the level of formality can vary.

Overall, the model allows the suggestion of the ideal zone to be clarified and it highlights the potential inefficiencies of the current route being taken by many companies. If a firm does desire formal systems then the optimum route would appear to be horizontally across the "ideal zone".

Work is now being undertaken using case studies to investigate different parts of the above diagram and the routes between these parts.

7. Research agenda

Further work is essential to identify strategically relevant issues for construction. At the Research Centre for the Built and Human environment we expect to make a contribution through an ongoing project on integrated delivery systems for sustainability. The key issues for this project are:

- A definition of sustainable development
- Key performance criteria
- A coarse model of the major factors involved
- An understanding of the key interactions between these factors
- A map of relevant knowledge, so identifying major gaps
- A research agenda to support potential progress.

8. Conclusions

It has been seen that sustainability issues cannot be meaningfully internalised and acted upon within construction firms if they treat sustainability (along with quality and health and safety) as a discrete problem with an isolated solution.

Environmental performance improvement requires strategic focus if it is to flourish, and add real value to organisational performance. Without direction, environmental management systems and initiatives will always be on the barren periphery of organisational behaviour, because they cannot meaningfully influence it.

An objective-nested, integrated approach, in contrast, encourages beneficial mutual crafting between sustainability and corporate objectives. This permits the focusing of organisation-wide effort by guiding and shaping a climate where strategically aligned environmental improvement intent can emerge anywhere in the organisation, and be translated into performance-enhancing action throughout the organisation as a whole.

The focus should be embodied in a hierarchy of objectives that infuse and maintain a distinctive strategic theme throughout the organisation. The development of these objectives should take into account as many stakeholder views as possible. Further, these objectives should form the central measure for assessing environmental performance improvement; and, in the same breath, these improvement efforts should critically assess, and if necessary change, the substance of these objectives.

Solutions for environmental management should not be taken at face value. The relevance of each approach should be judged per se, but only within the context of each firm and its environment. However, sometimes the approach followed may suit better the interests of the consultants selling it, rather than the company where it is actually implemented.

What Do We Mean By Sustainable Construction?

S.P. Halliday
Gaia Research, Edinburgh, Scotland

Abstract
It is no longer tenable to do other than seek sustainable development strategies, given that the alternatives are unsustainable development or no development at all. Serious debate is focused on the pace, and means of achieving sustainability and how it might be measured and targeted. The environmental performance of the construction industry is a cause for concern.

Buildings have a crucial impact on the physical and economic health and well-being of individuals, communities and the organisations which they are intended to support. They should enhance our quality of life. Yet they frequently contribute to ill-health and alienation, undermine community and create excessive financial liability. Modern planning is innately socially divisive and environmentally exploitative. Transport energy consumption is influenced both by planning policies, where they mitigate against mixed use development, and by the aesthetic and environmental poverty of much of the built environment which provides the impetus to travel. Out of town retail, business and science parks pass costs onto consumers and employees, encourage a culture of pollution and disempower non car-owners.

The Brundtland Definition of Sustainable Development talks about meeting the needs of the present and those of future generations [1]. Children born now may be alive in the 22nd Century and spending the greatest part of their lives, up to 90 per cent in industrialised nations, within artificial enclosures, just as we do today. They will not expect their buildings to constrain them as individuals, or communities, but to enhance their well-being, be functional, efficient, joyous and healthy. These are basic rights of individuals and basic needs of a society. There are examples of beneficial innovation, but the reward structure mitigates against the concern, ingenuity and resourcefulness which exists.

It is necessary for everyone involved with the construction industry to recognise the role of buildings and the extent of our responsibilities in creating a sustainable built environment. The paper will examine, through case studies at all levels, the cultural problems of the construction industry which have brought us to the present condition of 'a defensive response to a hostile environment'; to resource dependence and consequent ingrained pollution and to irrational responses. The case studies indicate both the contemporary dangers of the changes which are now required and a way forward to an improved, sustainable built environment for industry, commerce and building occupiers. It will become clear that if we are to contribute to the Brundtland objective the process of change can and must start immediately.

Keywords: Sustainable construction, culture shift, case studies, inter-generational, construction process, subsidiarity

1 Fragmentation

"How long can we pretend that the environment is not the economy, is not health, is not the prerequisite to development, is not recreation" C.Caccia[1]

1.1 Inside from outside

Over a period of time we have separated the inside of the building from the outside and made it the responsibility of the services engineer. In the past, buildings often made good use of microclimate, orientation, sunshine, natural light and air. The rapid growth in building services technology in the 1960's encouraged architectural vision to be context free. There has been an increasing tendency to replace natural systems: sun, shade, sensible cooling, natural light and air, building form and fabric, with energy consuming mechanical and electrical building services which are frequently more prolific than necessary, often difficult to operate economically and which create external local and global pollution. Designing within available limits is rarely perceived as a creative engineering challenge, generally it is not considered at all.

Design is driven by extremes and error margins, leading to oversizing and inefficiency under most circumstances, and ultimately making them difficult to operate economically, to meet real user needs, requirements and aspirations. These technologies present an ongoing burden with respect to running costs on a short term replacement cycle, which makes them a much more substantial aspect of the life cycle cost than is apparent from present emphasis on capital cost. Mechanical systems can also contribute to poor air quality, requiring yet more technology to resolve and adding to the vicious cycle of degradation. Yet, simpler and environmentally more benign solutions are often possible, with services operating as efficient supplements to natural systems rather than as substitutes. Passive ventilation, lighting, heating and cooling techniques have been developed in the last 20 years, which offer major unexploited opportunities in new and refurbishment situations. Much could be achieved by serious attention to traditional techniques, innovative development and contemporary knowledge, which may differ from conventional wisdom.

1.2 Buildings from location

Buildings have been removed from their climatic context. Because of the availability of fans and pumps and wires we now have a global architecture with little attention to the external climate or the availability of local resources, including human skills. Globalisation means designers can have identical facades or identical buildings climatically thousands of miles apart.

1.3 People from building

The underlying problem of using over-simplistic thermal standardisation is only slowly being unravelled. As clients were led to believe they could have universal comfort; environmental engineering became disassociated from building occupants as well as architecture and climatic context. But expectation with respect to building temperature continues to rise, bucking the laboratory mannequin. Standardised comfort design criteria sanctions 20% thermal discomfort within any interior. We should be wary of recent moves to standardise air quality.

1.4 Technology from people

We have increasingly separated technology from people by removing personal control and yet we have found that technology choice has a potent human dimension. We need to seek design solutions which rationalise building control and management to the available skills.

1.5 Product from process

We endorse fragmenting the professions and make the architect God of the pristine vision and the services engineer and supply chain the servant of its resolution. Division has encouraged us to forget that construction like creation is a process not an act. The design process traditionally stops at completion and encourages a fit and forget maintenance-free culture ignoring the downstream implications of design. Maintenance free means unmaintainable.

1.6 Us from them

It is difficult to know who to blame in the design process and the scapegoats are all too often the environmentalists. By fragmentation we have pursued Einstein's dictum that the environment is everything which is not me. But Einstein was wrong. Good air quality, clean and adequate water are the responsibility of the engineer.

1.7 Synthesis

Handy Hint No. 1: "Only connect*'

There is a move to break down the barriers and examples given will span the development of interdisciplinary design teams, process management documents which professionalise environmental design, formalised feedback such as PROBE, technical developments such as breathing walls, dynamic insulation and natural ventilation, flexible comfort bands with user controls.

2 Inertia

"If you are not part of the solution you are part of the problem"
Eldridge Cleaver[2]

2.1 Feedback

Handy Hint No 2: Use the precautionary principle

Precautionary action begins with learning from our own experiences and those of others. If we suspect a problem, or can envision a better solution, we should deal with it constructively and not talk it down. Every aspect of construction has a consequence which needs to be processed to aid future decision making. This requires feedback from buildings in use and innovative techniques. Feedback is a crucial part of any design and management process, and yet the UK's architectural and engineering work stages stop at completion. Feedback should aim to identify how good ideas in theory work in practice, and identity the most effective and cost-effective opportunities for significant improvement, to ensure that responses are adequate. All new building, and existing building management or demolition, needs to be undertaken with a view to minimising the long term liability of a building and its components. The challenge is inevitably context dependent and only rarely will there be 100 % right answers.

The argument against the precautionary principle tends to be that preemptive action is expensive, stunts beneficial innovation and may be unnecessary: Basically that now is optimal.

2.2 Delay

We are familiar with the global warming figures such as those expressed by the UK and other governments.[3] They are not very different from figures published in children's books in 1972.[4] Scientists investigating the effects of CFC's identified a problem with stratospheric ozone depletion in 1974.[5] Work in 1990 identified 25% of energy use in buildings could be saved cost effectively.[6] Research on life cycle analysis of buildings has highlighted the life cycle costs which make an absurdity of first cost accounting.[7] Yet this information has made only marginal differences to design activity and emissions from service systems are now the biggest single source of UK CO, pollution, and increasing faster than any other sector.

Handy Hint No.3: Try being an environmentalist for one hour a week. It won't hurt

2.3 Analysis Paralysis and Other Impediments

When we feel constrained we are good at creating further problems to solve. For example:

- sealing buildings to save energy and adding yet more building services to provide adequate conditions appears to have led to an increase in sick building syndrome and energy consumption has remained steady;
- adding layers of complexity to controls means that all too often expensive and impractical safety default mode is normal and not-evident except to the highly specialised eye.

Public recognition of the seriousness of environmental issues is accompanied by:

- It is not surprising that at a time of crucial change, too much time is being spent on combating misinformation; diluted marketing responses, unproven environmental claims and trivialisation; advertising is on the basis of any convenient element such as durability or energy efficiency without justification.
- genuine complexity requiring in depth knowledge is circumvented by bureaucracy such as environmental management systems which can readily create paralysis by analysis - without genuinely addressing environmental priorities.
- Professional environmentalism is welcome and long overdue but there is a danger that experience is being ignored with the consequences that errors made by amateurs are being repeated by professionals leading to a better quality of error!

- life cycle analysis dominates the pragmatics of a life cycle approach.

Examples will indicate a range of contemporary traps in the move towards implementation of appropriate strategies.

Handy Hint No. 4: Committed and meaningful action on all fronts

3 Tokenism

There is a mix of proactive implementation accompanied by half-hearted approaches and opportunist responses which may inoculate us against genuine and effective solutions. The futuristic green visions are emerging, and where they rely on the old theory of control and beating nature into submission they should be treated with scepticism. Examples will indicate a range of fantastic solutions and tokenist, impractical and expensive measures.

We now have a pretty good idea of the nature of the problems facing us and we need to design real solutions. Fortunately there are members of the construction industry who have pro-actively sought to offset what they believe to be risks and they deserve our respect and support.

4 Some Elements and Their Integration - Draft examples

Decision making may appear as a complex and difficult task, but professional are required to make decisions as a matter of course and the incorporation of environmental concerns is now a fundamental requirement. Environmentalism is now legitimate and professional assistance is available and there are simple principles which can be followed at a strategic level which will assist us to slow the rate at which we approach the carrying capacity of the earth.

Examples from a range of buildings indicate what can be achieved through:-

Replacement Materials & New Technical Opportunities

Insulation

A manufacturer initially disguised the fact that this insulation material was made from recycled newsprint because they thought that people would consider it an inferior product. It is now a thriving business and the hygroscopic properties of the material have opened up new technical options:- not least breathing walls (now in the Building Regs) and dynamic insulation.

Dynamic Insulation

Dynamic insulation seeks to break down the barrier between the inside and the outside, the services and the architecture. We are increasingly familiar with the notion of building physics but less so with building biology in which the building is an interactive membrane like our skin, like modem sports clothing. Dynamic insulation is being used in a sports building in Callander. It uses the building fabric as an active part of the ventilation system by creating a pressure differential through natural or mechanical means. The air is drawn through the porous membrane which operates as a buffer and reduces reliance on mechanical plant reducing stratification, air change rates and toxicity levels. [8]

Appropriate Components

Double glazed windows were not traditionally sealed, this only happened as a response to specialist gases. Over a period these have become packaged as maintenance free units. But maintenance free invariably means unmaintainable and either dramatic failure or fashion obsolescence. There is evidence that gas-filled window systems have failed after quite short periods of time and a Norwegian designed a triple glazed window which performs well in the long term, costs the same as a double glazed unit and is maintain able. [9]

Clean Energy Technology

Solar Air Conditioning

Desiccant cooling technology, which uses low temperature heat, opens up the potential for solar air conditioning (a/c). Given the predicted rise in the need for a/c it seems ecological and serendipitous to combine these techniques while we determine a better long term strategy. [10]

Passive Solar Design

A range of new and refurbishment projects which utilise passive solar design. [11]

Renewable and Hybrid technologies:

Projects which source their energy from local and renewable sources including wood chip boilers. [12]

Burner Technology

Regulatory response to acid rain was swift and there has been significant innovation amongst boiler and burner manufacturers.

Materials

Detoxification .

Non-Chemical Treatments- Architects called upon to chemically treat loft timbers for insurance purposes worked with a consulting company to develop a ventilation system which would ensure that the beams were protected. They got insured, breaking the unholy alliance between the chemical and insurance companies, and saved significant amounts of money.

Benign Specification- Materials and finishes [13]

Materials Audits- Most products and processes were designed before environmental issues were fully under stood and process studies are able to identify cost effective efficiency measures to reduce energy use and chemicals.

Clean & Conservative Water Strategies

Water Management Technology

Living machine as a biological waste treatment cycle.

Reed Beds

Composting

Community

Agenda 21

When faced with the prospect of a major refurbishment, Oxford County Council decided that they wanted to make the best of new knowledge developed in the intervening 30 years. They looked at adaptive comfort theory, energy efficiency and personal control issues and decided to try openable windows, which they did to a small degree under experimental conditions. The occupants expressed a prefer in a city centre site for openable windows despite the external noise and possible air quality issues. One might have assumed that they would then be concerned that conditions in the urban environment could get worse. Yet they turned to the local authority Agenda 21 strategy, the commitment to continual improve, to justify their decision for the long term. [14]

Handy Hint Number 5: Audit your product or service for cost-effective environmental saving Now is not optimal

Handy Hint No.6: Process the consequences of expediency

Handy Hint No 7: Reconsider Darwin who described evolution as survival of the fittest

Nothing lasts for ever but successful evolution involves the ability to diversify quickly and decisively in response to changes in circumstance. Survival rests not with the fittest but with those who are most fitting

5 Intergenerational Solutions

"It is an injustice, a grave evil and a disturbance of right order for a large and higher organisation to arrogate to itself functions which can be performed efficiently by smaller and lower bodies." Quadragsillo Anno [15]

Sustainability isn't just about the environmental ether. It is also about social fabric and value systems, about educating children who can educate their children, building lasting communities, enhancing the world and not neglecting it. It is about developing permanent cultures with an ethos of continual improvement. It is about dignity. The UK commitment to sustainable development has been translated as 'intergenerational responsibility', and it seems appropriate that initial planning for a long term development should have the participation of the eventual users. The Brundtland definition refers to "development which meets the needs of the present without compromising the ability of future generations to meet their needs". We should remember that we are still far from meeting the needs of today. In many areas, poor quality housing and schools, lack of amenity, poor transport infrastructure and high unemployment, combined with lack of investment and vision have conspired to create low expectation, low achievement, state and utility dependence and atrocious environmental performance.

By involving children in the planning process for a major development in Edinburgh it became clear that they are very discerning, they want safe areas, jobs, good quality housing, soft and clean technology, wildlife corridors, schools that didn't leak, a children's parliament, everything we are failing to provide. If we expect children to be good citizens shouldn't we be respecting their genuine needs and desires. What can we expect from them when we display bad stewardship and give them so little of lasting quality.

If we are successfully to implement Agenda 21, then experienced consultation and planning strategies are required to transform these estates, which present major opportunities for benchmarked improvements from net sinks, to balanced, safe, healthy and productive communities of the future.

6 Building In Solutions

"Creation is not an act but a process" Theodosius Dobzhanskey [16]

Construction activity extends from inception to demolition and beyond to recycling of components. Decisions at each stage will positively or adversely effect the economic, social liability and ecological impact. Buildings generally last a long time and badly designed buildings inflict unnecessarily high demands on the environment and are a poor legacy for future occupants and future generations. If they are demolished prematurely they represent a wasteful use of capital and human resources and embodied energy and water. Building components are increasingly indestructible composites. As well as embodied energy and embodied water and pollution, we also see the rise of embodied disposal cost.

But the most important decisions, affecting the impact of a building, are taken at the earliest stages in building conception and design. Unfortunately, the tendency remains for the architect to design and the engineer to service with minimal regard for issues within their grasp to influence.

Less than ideal buildings result from poor communication between the disciplines and their differing priorities, yet everyone could make a constructive contribution. Procurers can achieve a great deal by establishing a brief within an ecological context and by moving away from the unhelpful syndrome of lowest capital cost and supporting design selection and plant procurement on the basis of life cycle cost and environmental impact. Similarly, designers must learn to think about passive systems and issues leading to over design and inefficiencies.

They should pay attention to detail and give forethought to manageability, and the needs, requirements and aspirations of users. Cost professionals need to find mechanisms for integrating architecture, structure and services strategies on the basis of life cycle costs. Professional institutions need to lobby at high level for sensible pricing policies and appropriate fee structures which respect society's needs and the wider environment. They need to promote life cycle, passive and inter-disciplinary approaches to design and material selection, while setting responsible strategies for seeking genuine solutions and combating misinformation. (contractors and suppliers can contribute by minimising wastage, pollution, hazard and risks associated with their products, services and working practices. Even quick look audits can identify cost-effective environmental opportunities for improvement. Owners and occupiers could assist by sound management and seeking continual improvement, while everyone could assist by recognising and pursuing quality.

7 Culture Shift

"Infinite growth on a finite planet is an impossibility." Fritz Schumacher [17]

We have been encouraged to believe that consumption is a measure of success, yet it is increasingly evident that the ability to meet social goals with the minimum use of resources, and minimum waste and pollution, is the mark of a successful society. The main requirements are not for increased complexity, but for more care and forethought, more attention to the environmental impact of material and energy supplies and more focus on the genuine needs of organisations and users.

We cannot continue to divide the responsibility, perpetuate the inertia, respond with tokenism or invent more problems. We need a discerning reward culture and truly inter-generational solutions.

A culture shift is fundamental to the pursuit of sustainability, and the direction of this shift is becoming increasingly evident. The common features are a move from the scientific, reductionist world view to a holistic world view which began with Fourier and Owen and was developed into an applied human ecology by Geddes. Ultimately the question must be "what kind of built environment do we want?" What can we expect from subsequent generations when we have created so little of lasting quality and value?

It is traditional to read Darwin's 'survival of the fittest' as the biggest, the boldest and the strongest. But it is becoming increasingly clear that survival is the domain of those most fitting in the face of ecological limitations, to which we must all ultimately defer.

Environmental management in Denmark from development programmes to practice

I.S. Olsen
Danish Ministry of Housing and Building, Copenhagen, Denmark

Abstract

In the Danish building sector, environmental management is currently being implemented in three areas: design, construction and operation of buildings.

This innovation is based on development programmes which have been completed in the last few years. Dissemination and incorporation of the results of these programmes are being closely monitored.

Common to all the development programmes is a requirement that building clients and companies formulate an environmental policy describing attitudes, goals, priorities and organisation.

The next step in the individual building projects is an environmental review to map environmental factors. This is followed by an environmental action plan as the basis for start-up of environmental management.

Lastly, environmental audits are carried out to check that the environmental management system works properly and that the goals are being achieved.

Environmental management in the three areas in question: design, construction and operation, is based on these elements. In practice, environmental management differs in the three phases because the content and the parties differ from phase to phase.

Key words: Sustainability, environmental management, design, construction, operation.

1. Environmental management - why?

The move towards sustainable building has long been characterised by a major effort to save resources - energy, electricity and water - during use of buildings.

However, the possibilities for environmental measures have grown and there are probably now between 100 and 200 available to use - a veritable ecological supermarket.

To get a better and more complete picture in each building project of the best solutions there is a need for systematised, interdisciplinary analysis of the various options.

For this reason, three development programmes have been used to develop new methods of management and control of the design, construction and operation of buildings. The methods in question give greater priority to integrated assessment of environmental impacts from new buildings and from the operation of existing buildings.

Environmental management is built up around four basic elements, which appear in all three programmes.

Building clients and companies must formulate an environmental policy aimed at continuous improvement of environmental performance, firmly placing responsibility and authority and laying down goals and guidelines for monitoring of the results.

An environmental review maps the environmental factors, measured - for example - by impacts on resources, the surrounding environment and people. The next step is an environmental action plan, containing an activity schedule and time schedule for the actual environmental work, with responsibility, authority and environmental tasks assigned in accordance with the environmental policy.

Environmental audits are the means by which it is checked that the environmental management system is working satisfactorily and that the targets set have been achieved. The audits can be used as the basis for an environmental performance report, making the results achieved public.

2. Design - the first step

The first step towards better environmental management is new design methods.

In Denmark, a development programme for “Environmental management in project design” was finished in 1998.

In accordance with this programme every building project should start with mapping of the relevant environmental factors. The most appropriate and financially advantageous measures will naturally depend on the local situation.

It is important to carry out an integrated assessment of the possible areas for action.

The programme differentiates between impacts on our resources (what is removed), impacts on the surrounding environment (what is added) and impacts on people (during construction and later operation). The impacts can be reduced by various means, such as choice of materials, ensuring replaceability, reuse/recycling and substitution.

The building client must therefore ensure that an integrated interdisciplinary analysis is carried out to pinpoint the main - say 1 O-1 5 - environmental factors to which particular attention must be paid in the performance of the project.

The design work must be based on the chosen areas for action. In other words, an environmental policy must be drawn up and environmental objectives specified for the building project in question. This must be followed by an assessment of the consequences for the design of the building, including the choice of structures and installations.

The new design practice is thus based on cooperation between the building client, the architect and the consulting engineers on the formulation of an environmental programme based on the environmental objectives.

The next step is to draw up an environmental plan showing how the programme is to be fulfilled in practice. Lastly, the environmental action is documented in an environmental balance sheet.

The environmental objectives may, for example, include the building's relationship with its surroundings, its resource consumption, lifetime, maintenance, reuse/recycling potential, working environment, energy consumption and indoor climate.

For example, special solutions may be chosen - form of ventilation, materials, surface treatments and sun-screening - that fulfil the requirements with respect to indoor climate. Quality assurance and environmental management go hand in hand here - quality assurance ensures that the environmental objectives are achieved.

In connection with the development programme a database is being established with general environmental information on all main building materials and a guide to gathering specific information from manufacturers.

3. Environmental management at the building site - second step

In the construction phase, too, there is a need for systematic monitoring - for example, of the consumption of energy and water, handling of waste, noise, odour problems and dust.

A couple of examples will suffice to show the importance of such monitoring: transport in connection with building and civil engineering work accounts for about 45 % of Denmark's total transport of goods by lorry, and the building industry accounts for 3 % of Denmark's total energy consumption.

There are at present three main standards for environmental management: the British Standard BS 7750, the EU's EMAS Regulation and the international standard IS0 14001.

In a Danish development programme called "The Contractor's Environmental Guide", a compendium of information material has been put together as support for the introduction of environmental management at contracting firms. The material, in the form of booklets, guide, eco-file and a video, is addressed to different levels within the contractor's organisation.

During the performance of a project, quality assurance and environmental management can be integrated and taken care of in two ways. Firstly, the building client must ensure that the agreed quality is achieved in the chosen areas - cf. above on indoor climate - and, secondly, the contractor must monitor the work at the building site with respect to its environmental consequences - waste, noise, odour problems, dust, etc. - as mentioned above.

4. Environmental management during operation - the third step

The basis for the operating plan is the owner's aims with respect to the exterior appearance of the building, the building's indoor climate and other utility functions, its energy consumption, and its state of maintenance.

It is natural to integrate environmental factors with the operating plan. In the above-mentioned example concerning indoor climate, the points mentioned - ventilation, materials, surface treatments and sun-screening - must thus be included in the operating plan

It may be appropriate to go one step further, since studies of resource consumption during operation of buildings show big differences from one housing unit to another, and experience with reduction of energy consumption indicates clearly that awareness and motivation on the part of the occupants are absolutely essential for achievement of a lower consumption.

Mapping the actual consumption in a housing unit or an apartment building, for example, and information about what other households use - possibly what the best **30 %** use - enable the occupants to opt for a given consumption - low or high.

In the Danish programme "Environmentally Managed Building Operation", a new approach to operation has been developed.

According to the resulting guidelines the consumption is mapped, the occupants choose an objective for the building's future consumption, and an action plan is drawn up for achievement of the objective.

The most obvious areas for action are consumption of energy, water and electricity and handling of waste. In these areas it is relatively easy to record the consumption. In the longer term, it may become relevant to include other areas, such as indoor climate and noise level.

In other words, integration of quality assurance and environmental management in this area means both achievement of the objectives set up in the design phase and continuous assessment of the operation of the building, with the possibility of improvements.

5. Conclusion

The new methods for environmental management make it possible to work with environmental factors in a more planned and systematic way.

Experience from the Danish development programmes show:

(1) That environmental management should be integrated with <u>the normal work</u> processes
(2) That environmental management should be carried out in a <u>close cooperation</u> between all the parties involved in a building project
(3) That environmental management should be planned so that the work follows the normal, <u>progressive decision-making process</u> in a building project
(4) That environmental management should <u>start as early</u> as possible and be both interdisciplinary and long-term
(5) That <u>prioritisation</u> is essential and that the most serious problems must be kept in focus

(6) That environmental management should be visible all the way through - from the design phase, through the construction phase, to and including the operating phase

In the years ahead, Danish building firms are going to have to incorporate the principles for environmental management. In the long term, this will result in a shift in the way building clients and firms work in the direction of sustainability and will also bring financial advantages.

A practical approach to life-cycle economy

I. S. Olsen
Danish Ministry of Housing and Building, Copenhagen, Denmark

Abstract
In the financial management of housing projects, the main focus of attention has traditionally been the construction costs. In recent years, however, the view has evolved that account should also be taken of the subsequent operating costs. In Denmark this has led to a new law requiring a life-cycle cost assessment in connection with the planning and design of subsidised housing.

A housing project's life-cycle cost include a capitalisation of the total cost of construction and operation during the life-cycle of the project or for a specific period of time. The operating costs comprise maintenance, cleaning, electricity, gas, water and heating, and general operating costs, such as caretaking, taxes, insurance and charges.

A life-cycle cost assessment makes it possible to balance the construction costs against the operating costs. For example, different installation solutions can be assessed on the basis of the total cost, i.e. the combined cost of construction and subsequent operation. The same can be done in the case of structures and surfaces.

A life-cycle cost assessment could thus lead to higher construction costs if it showed that this would result in savings in operating costs that exceed the extra investment.

However, this type of assessment could also indicate other benefits - relating to environmental aspects, for example. Improvements in this area could thus be deemed worth some extra investment.

In connection with the new act, the Ministry of Housing and Building has had a special PC program designed by the consulting engineers Birch & Krogboe. The new program provides a simple means of carrying out a life-cycle cost assessment of a housing project.

In this connection, the Ministry has launched a development project aimed at facilitating assessment of the sustainability aspects in connection with the life-cycle economy of housing projects.
Keywords: Life-cycle economy, PC program, sustainability.

1. The basis

Life-cycle cost assessment implies estimation of the uncertainties and future risks involved in the development of a project's operating costs.

In the last 5-10 years methods have been developed for life-cycle cost assessment. In Denmark, interest has focused on calculation of the net present value, in which the operating costs are discounted to the time of construction and added to the construction costs, cf. the reports mentioned in the references.

The main features of the new PC program are as follows:

When a few values for the locality have been entered (such as supply prices in the area in which the planned project is going to be situated), together with the size of the project, both the construction costs and the total life-cycle economy of a reference project can be calculated. The calculation is based on the known costs for the construction and operation of traditional housing, Here, traditional should be understood to mean that the structures, installations, surfaces, etc. are in line with normal practice for low-rise and high-rise housing.

In the next step, data are entered for the planned housing project. This is done by altering the data for the reference project - although only the items where the planned housing project differs from the reference project. The program then computes the construction costs and life-cycle economy of the planned project.

The uncertainty of the calculations is given for both the reference project and the planned project. A full analysis of the proposed solutions in the planned project is then carried out in which account is also taken of architectural and environmental factors.

In order to design a program that is simple to use in practice it has been necessary to make a number of assumptions concerning such matters as lifetimes, inflation and return on investment. This input is thus not based on actual calculations.

Use of the program in a number of experimental housing projects will be monitored for one to two years as a basis for determining its usefulness.

One of the problems of life-cycle cost assessment is the uncertainty of the operating data. The work of gathering experience in the various operating areas is therefore going to be intensified.

Life-cycle cost assessment in connection with planning and design provides a better basis for assessing the construction costs and the general quality of a housing project. However, it is also important to carry out a critical review of the computed values.

2. Calculating principles

The calculation of the construction costs for the reference project is based on a chart of accounts with 65 items, largely in line with the SfB-system's table of building components. For each building component, values are specified for minimum, maximum and probable cost, corresponding to the 10% fractile, the weighted mean value and the 90% fractile.

For these 65 items, the cost of maintenance is also calculated, as a percentage of the construction cost, and upkeep (planned maintenance), as a percentage of the construction cost, taking into account the estimated lifetime of the building component in question. The above-mentioned fractiles are also used here.

Cleaning costs are included in the maintenance costs.

29 items relate to services (electricity, gas, water and heating) - e.g. heating of apartments, consumption of hot utility water and losses in connection with heat production.

The service costs are based on standard key figures for consumption and information concerning local supply prices (which are entered by the user).

Lastly, there are general operating items, which include caretaking duties - snow clearance, care of technical installations, stair-washing, etc.

The figures for general operating costs are given per square metre floor space and are based on experience.

In the calculations for the reference project, account is taken of the fact that the prices for both construction work and operation can vary from region to region, cf. below. The actual location and the actual supply prices must be entered. Data are also entered concerning the size of the planned housing project, the number of dwellings, etc. The result is thus a reference project that corresponds in size and location to the planned housing project.

The program computes the life-cycle economy and net present value, total and per square metre, for the reference project.

The planned project is then modelled as changes to the reference project. The construction costs for the various building components are given as a percentage of the total cost.

For maintenance, the percentages can be changed correspondingly. For example, the extra investment needed for energy-saving measures could be offset by a gain on the supply side. However, the extra investment might also imply bigger costs for maintenance, upkeep and general operation (caretaking).

For the operating costs, changes can be made to the quantities for consumption and the cost of upkeep (by changing lifetimes) and to the general operating costs (by changing prices). It is important to carry out a realistic assessment of the operating costs of new solutions. For example, special fittings may considerably reduce consumption but also require better care. That may demand more of the tenants.

The program uses a 30-year period, a nominal interest rate of 5% for estimating purposes and a rise of 2% in the price of services.

The lifetimes used for materials are based on available information.

In addition, various assumptions are made concerning both construction and operating costs. That applies, for example, to water consumption per tenant, number of tenants per dwelling, consumption in communal rooms, heat and electricity consumption, and waste.

It is estimated that it takes 10-20 hours to run the program in.

The program can also be used for the individual building components, keeping other factors constant.

3. Application in practice - examples

Before publication in January 1998, the program was tested on some planned housing projects.

One of these projects is a sustainable housing project in Aarhus, which is one result of the Danish Minister of Housing and Building's action plan for sustainable housing. A similar project, based on the same general principles, is under construction in Ikast.

In the computation of the planned project, the following construction items were changed because of special environmental measures:

Heating installations in the apartments (due to solar heat system), fans (due to ventilation system), fittings in the apartments (due to CTS-system), windows and doors (due to super-insulating glazing), and stormwater pipes by buildings (due to reuse of roof water).

These extra investments result in a total increase in construction costs of DKK 721 per m^2 floor space.

The extra investments result in changes in the operating costs for the planned housing project in relation to the reference project. The changes concern the following:

Cold utility water for apartments (water saving due to use of roof water), heating of apartments (heat saving due to solar heat system, ventilation system, CTS-system and super-insulating glazing), heating of apartments (operating costs for the said systems), power and lighting in apartments (operating cost as a consequence of the solar heat system and ventilation system).

In all, operating savings amount to DKK 32.6 per m^2 and operating costs to DKK 12.1 per m^2, resulting in a total saving on operating costs of DKK 20.5 per m^2 floor space.

The calculation of the present values shows an increase in the life-cycle economy, per m^2 floor space, from DKK 13,256 to DKK 13,591, with an uncertainty of DKK 8 16 and DKK 825, respectively.

In the housing project in question there is thus a small increase in the life-cycle cost. However, special funding has been obtained for the extra investments, which are not incorporated in the program, and that ensures the same life-cycle cost.

Special financing has also been obtained for the extra investments needed in the parallel housing project in Ikast. In this case, however, there is in all a small increase in the life-cycle cost, calculated per m^2, from DKK 13,708 to DKK 14,134. Here, however, the extra investments are deemed to be so valuable for environmental reasons that the project is being built with the calculated life-cycle economy.

It can be added that the construction costs for the said housing projects amount to 60 to 65% of their total cost.

4. Life-cycle economy and environment

In connection with the programming and design of a project, the client, in consultation with the consultants, must consider the environmental aspects of the project. The choice of materials, structures, installations, surfaces, etc. all have consequences for both the life-cycle assessment and the project's sustainability - in other words, its environmental impact.

Some of the consequences will have a direct effect on the project's life-cycle economy. For example, the installation of a solar heat system will necessitate an extra investment and result in a saving in operating costs, both of which can be directly measured in the project's life-cycle economy.

Other consequences are more difficult to measure and will not feature automatically in the life-cycle cost assessment. For example, changing surface treatment, joints and floorings may affect the indoor climate but will not necessarily be reflected in the assessment

A lot of work is going on at present to determine the properties of a building that affect its environmental impacts - the consumption of resources (energy, materials, water and land), the impact on the building's users (working environment and indoor climate), and consequences for the external environment (climatic impact, air and water pollution, and handling of waste).

By using the results of a recently concluded development project "Environmentally managed design", a client and its consultants can systematically map and assess the environmental impacts of a planned project. Through a dialogue, the client must decide on the environmental objectives for the project.

Some of these environmental objectives cannot be translated into a common measure, as kroner and ører in a life-cycle cost assessment. However, it is possible for the client to set up criteria for the various actions that provide a basis for assessment.

To this end, the Danish Building Research Institute (SBI) is working on reference limits for the principal impacts - for example, consumption (of energy, water and materials), acceptable emissions (such as CO_2), measures (for building waste, reuse/recycling and waste water), criteria for indoor climate (measured by humidity, fibres and ventilation), etc.

These reference limits will give clients and their design consultants a better basis for discussing the environmental objectives for the planned project.

Where there are Agenda 21 plans for the local area, they should be included in the evaluation and determination of environmental objectives.

A real comparison between the reference project and the planned project can be obtained by calculating the environmental impacts of both projects. The basis for the comparison is the statement of quantities of materials, consumption on operating items, etc., with assessment of the associated environmental impacts. For the reference project, a greater knowledge is needed of structures, installations, etc. than the aforementioned "normal practice" in connection with the calculation of life-cycle economy.

Lastly, it must be mentioned that the visible operating items in the life-cycle cost assessment provide a natural basis for the preparation of green accounts. These accounts are an aid to continuous collection of data from practice and thus offer a better basis for future life-cycle cost assessments.

As a general rule, it is important to look not only at the life-cycle economy of a project but also at its environmental consequences. An extra investment and higher life-cycle costs may be found acceptable if the environmental benefits achieved are deemed to be higher than the extra investment, as in the case of the above example.

5. Local conditions

The local conditions can have a big effect on the calculation of present values. This applies not so much to the construction costs as to the operating costs relating to the supply of water, heating and electricity and to waste handling.

In other words, the optimum sustainable solutions may vary from place to place.

For example, the heating installation, calculated in present value per dwelling, varies from DKK 132,000 to DKK 158,000, price level January 1994, including 25% VAT. The variation is due to both differences in the technical solution and differences in the "pricing policy" in the area in question. In this case, the use of solar heat will thus not be the best solution from the point of view of life-cycle economy, but may be so from an environmental point of view.

It should also be mentioned that the price with use of district heat can vary by a factor of 4, reflecting the fact that district heat suppliers charge very different prices.

For the drainage installation, the present value per dwelling varies from DKK 59,000 to DKK 109,000. A factor that plays a role here is whether a charge is payable on saved waste water because of percolation of stormwater.

<u>In other words, such factors as connection charges, fixed charges, investment contribution, metered billing, and regular waste-water charge, can affect the calculation of a project's life-cycle economy.</u>

6. Conclusions

For a housing project, the construction costs account for 60-65% of the total life-cycle cost, assuming a lifetime of 30 years. It is therefore not just the construction costs that must be considered when deciding between different solutions, but the entire life-cycle economy.

For the Danish Ministry of Housing and Building, the consulting engineers Birch & Krogboe have designed a large PC program as an aid in the assessment of the life-cycle consequences of different choices during the planning and design of housing projects.

The main features of the program are as follows:

- After some few values concerning supply prices etc. and the size of the planned project have been entered, the program computes the construction costs and the life-cycle economy for a <u>reference project</u>. This project corresponds to normal practice for low-rise and high-rise housing.
- The life-cycle economy of the <u>planned project</u> can then be calculated by changing the data for the reference project where these differ from the planned project.
- The <u>uncertainty</u> in connection with the calculations is given for both the reference project and the planned project. A complete assessment of the proposed solutions in the planned project can thus be carried out. It is important here also to pay attention to architectural and environmental factors.

- The environmental factors must be clarified through a dialogue between the client and its consultants aimed at determining environmental objectives for the project. It is important to note that some of the environmental consequences of different choices will be reflected in the life-cycle economy, while others will not necessarily be reflected in it.
- The local assumptions, especially those concerning supply prices, will vary from place to place. If only the life-cycle economy counts, this means in practice that "pricing policy" may determine the choice of solutions.

The program is a valuable and speedy aid in life-cycle cost assessments. However, the results must be subjected to a critical review in which account is taken of other aspects, such as architectural and environmental factors.

Intelligent Environmental Modelling of Building Performance for Sustainable Design

K. Beattie, I. Molloy
Dublin Institute of Technology, Ireland
I. Ward
University of Sheffield, England

Abstract
A sustainable approach to building design is now essential. Sustainability emphasises relationships rather than pieces in isolation. By taking a holistic approach and using the interrelationship of the sun, wind and the building's form, layout and orientation a building's design can be optimised to achieve the maximum contribution of natural light, natural ventilation and solar heating. This significantly reduces the requirements for using up fossil fuels, limits carbon dioxide emissions to the atmosphere and contributes to sustainable building design. Intelligent environmental modelling of buildings is required to optimise this design approach. This paper presents new state of the art dynamic simulation software, which allows a range of environmental performance assessments to be carried out on a building's design using one computer model of the building. Simulation results are included for solar analysis, natural ventilation analysis and daylight analysis as well as total energy requirements. Buildings that have been designed using the software have resulted in significant reductions on the impact these buildings have on the environment. A case study building is included as an examplar of this new design. This building is using 81% less energy and producing 64% less CO, than a conventionally designed building.
Keywords: Intelligent environmental modelling, dynamic building simulation software, sustainable design, environmental performance assessment, simulation modelling.

1.0 Introduction

We are becoming more and more aware of the impact that the construction of the built environment is having on the environment. Rogers [1] advises us that mankind's habitat – our cities – is the major destroyer of the ecosystem and the greatest threat to humankind's survival on the planet. Boonstra [2] has found that 50% of the material resources taken from nature are building-related and 40% of the energy consumption in Europe is building-related. Agenda 21 endorsed at the Earth Summit in Rio de Janeiro in 1992 is a major blueprint for how the world's nations can work individually and collectively towards sustainable development for the 21st Century. One of the major aims of Agenda 21 is to reduce the amount of energy and raw materials society consumes. As we attempt to comply with the concepts of sustainable development we need to address very seriously the impact of the construction industry on the global environment and significantly reduce the amount of energy used for our buildings.

Baker [3] investigated the factors upon which the energy performance of non-residential buildings depended and concluded that building design accounted for a factor of 2.5 in their energy consumption and building design and systems together accounted for a factor of 5 in the energy consumption. Better designed buildings and their systems can therefore play a major role in reducing the energy consumed and the impact buildings have on the environment.

In order to evaluate the most significant design parameters accurate information should be available at the early design stage as it is at this stage that the most reduction in environmental impact can be made.

Dynamic building simulation software is now available for use from the early design stage to examine the interrelationship of the building's form, layout and orientation with the sun and wind. In this way a building's design can be optimised to achieve the maximum contribution of natural light, natural ventilation and solar heating.

2.0 Sustainability in our societies

The concept of sustainability has been around for a long time, although only recently has it entered popular culture. The modern roots of sustainability began in the early 20th century theory of renewable resource management, most notably in sustainable agriculture and forestry, and in theories of "sustained yield." However the concept of sustainability has now become the integration of human, social, cultural and economic development previously studied and dealt with separately.

The modern sustainability movement began when The World Commission on Environment and Development, through the Brundtland Commission, released their report "Our Common Future" in 1987. The Brundtland Commission defined sustainability as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs."

The Brundtland report has been reviewed variously as clever green repackaging of the status quo of international trade and finance, or alternately as a sign of hope for the human race. The Bruntland definition of sustainability is widely used and has brought more people into the discussion on what is necessary for sustainable development.

As we find out new information on the damage being done to the Earth's eco-systems and as world population continues to increase different standards may be required for sustainability. Sustainability is thus a complex and evolving issue.

More attention is now being paid on how to produce things with less energy and with less damaging ways of supplying this energy. Information technology is also offering a huge increase in access to knowledge and communication without much expenditure of energy in the equipment itself and reducing the need for transport. This may lead to very different lifestyles in the next century. Building designers need to use the new information available and a new design methodology to produce low environmental impact buildings.

3.0 Simulation modelling

Recently developed state-of-the-art dynamic computer simulation software allows a range of performance assessments to be carried out on a building's design using one computer model of the building. The software is built around the Environmental Systems Performance (ESP) program researched and developed at the University of Strathclyde, Glasgow. ESP has been tested in a number of EU projects. On the basis of these and other findings the ESP program has been declared the European Reference Model for Passive Solar Design.

3.1 Simulation methodology

Zones within a building are defined in terms of geometry, construction and occupant profiles. Zones are then interlocked to form a building and leakage distribution is defined to enable airflow simulation. The plant systems network is then defined (if one exists) by connecting individual components. The multi-zone building and multi-component plant are connected and subjected to simulation processing over a user defined period (from 1 week to 1 year) using hourly values of weather data obtained from the meteorological office.

At the early design stage ESP is particularly powerful since it can be used to quantify the performance impact of the site, the building geometry and construction: all factors which have considerable impact on energy performance and costs. At the more detailed design stage ESP allows the designer to focus on issues of comfort and control.

Other programs in the suite can carry out performance assessments which include daylight analysis, solar energy analysis, natural ventilation analysis, detailed air velocity, temperature and relative humidity analysis, visualisation analysis and CO, SO, and NO, emissions. The use of one computer model of the building for all the performance assessment evaluations means that building geometry need only be input once. Another advantage is that when for example trying to optimise the building's facade design in terms of thermal performance, natural ventilation and daylight, results are analysed based on the same window design, percentage glazing ratio, obstructions from adjacent buildings etc. The model of the building can be easily updated to allow many evaluations of the significant design parameters.

The software provides information for the team (client, project manager, architect, mechanical and electrical engineer structural engineer and quantity surveyor) involved in the design of a building project. The design team members communicate through the Virtual Reality Model of the building. The model of the building is produced by the 4D modelbuilder program -see figure I below. The software can be used to provide the clients design brief and then support the design team from the initial sketch design phase, through detailed design and construction.

3.2 Performance assessment	**simulation program**
• Building Capital Cost Analysis	Ideal
• 3D Visualisation	Rove
• Visual Impact Assessment	Landform
• Detailed Lighting Simulation	Radiance
• Solar Shading Analysis	SunCast

• Microscopic Air Flow Analysis	MicroFlo
• Simulation Results Analysis	XTRA
• Dynamic Thermal Simulation of Building & Plan	ESP
• Costs and Emissions to the Environment	Ergon
• Smoke & Fire Simulation	Jasmine
• Occupant evacuation	Simulex

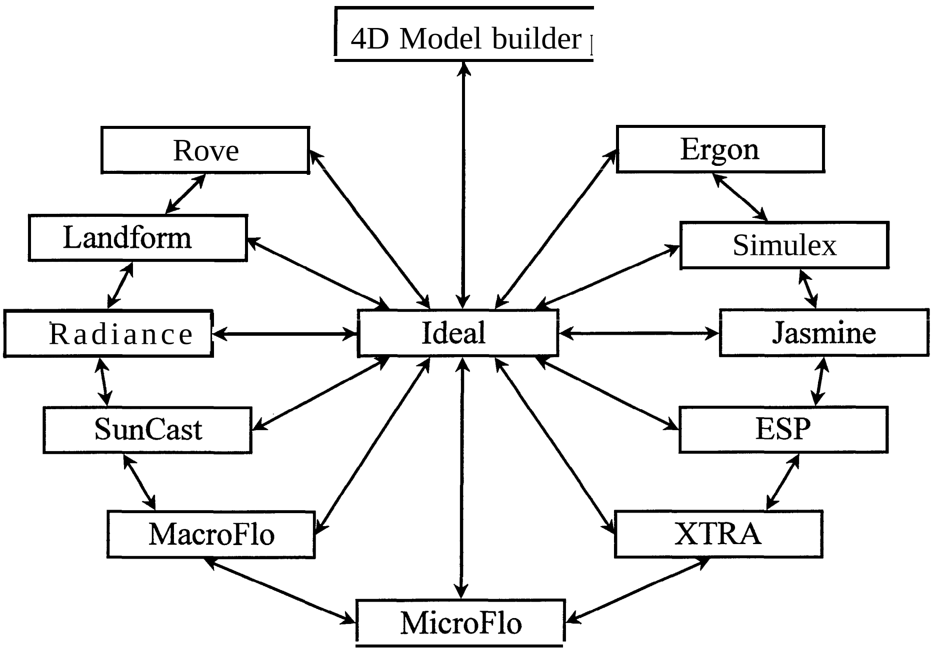

Figure I Performance Assessment Simulation Programs

4.0 Sustainable building design

The criteria for evaluating sustainable building design is being investigated and researched by an increasing number of groups some of which are the Building Services Research and Information Association (BSRIA) in the UK, The Earth Centre at Denaby Main, South Yorkshire UK, as well as CIB. The outcome of this research is eagerly awaited.

In the context of this paper sustainable building design is considered to be the use of the interrelationship of the sun, wind and the building's form and orientation so that the building's design can be optimised to achieve the maximum contribution to natural light, natural ventilation and solar heating This eliminates the requirement of using fossil fuels and carbon dioxide emissions to the atmosphere and contributes to sustainable buildings.

5.0 Building environmental performance optimisation

In order to optimise the building's environmental performance a number of assessments can be carried out using the simulation software. Typical assessments that can be carried out to optimise the design in terms of maximising the contribution of solar energy and daylight and using natural ventilation are explained below.

5.1 Solar analysis

The SUNCAST program is used to evaluate the effect of obstructions on the solar performance of the building model over the year. One example of shading that occurs from adjacent buildings at 16.00 hours is shown in figure II. The hourly values of available solar energy calculated over the year using this program is transferred to the ESP program and the solar energy contribution is subtracted from the heating energy requirements. The parameters that affect the solar performance of the building (e.g. orientation, form, and window design) can be easily changed in the model of the building and the new design evaluated. In this way the solar energy contribution can be maximised. The best position for photo voltaic panels can also be established using SUNCAST. Sustainable design may initially seem suitable only for green-field sites. However the use of this simulation program can increase the possibilities for sustainable design in urban locations.

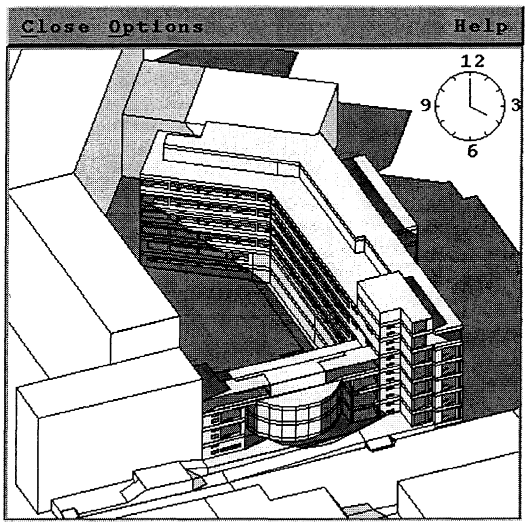

Figure II

5.2 Natural ventilation analysis

The Macroflo program is used to determine the airflow through the building to ensure that the natural ventilation strategy will work. The program calculates the airflow between the zones in the building and outside and takes into consideration the wind speed and direction, the difference in outside and inside temperatures and the stack effect created by the chimney between zones 1 and 9 – see figure III. The effect of louvres and their control on the ventilation requirements can be simulated and checked using the Macroflo program. The building design is also checked to ensure that there are sufficient openings in the correct locations to ensure adequate natural ventilation. To achieve sustainable design means trying out innovative design methods and the simulation software should be used to assess new methods. The Macroflo program is also used to check the layout of the building as the height and position of internal partitions may have an adverse effect on the natural ventilation strategy.

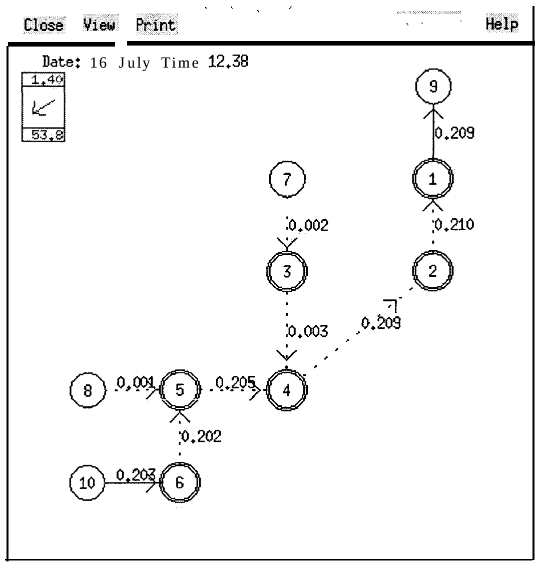

Figure III

5.3 Daylight analysis

The RADIANCE program is used to evaluate the contribution that proper daylight design can be used to reduce the artificial lighting requirements for the building. The generation of electricity can have adverse effects on the environment so maximising the contribution of daylight is very beneficial. Natural light in buildings also has positive effects on the building's occupants. The optimum blade angle for window louvres can be designed and tested. The program can also identify any possible problems arising from glare, see figure IV.

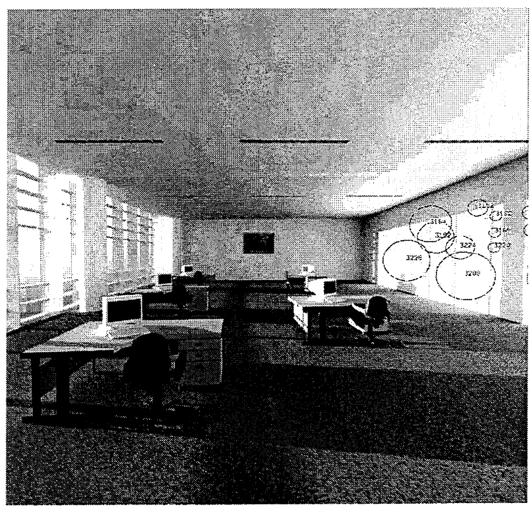

Figure IV

5.4 Orientation and façade glazing ratio

The ESP program considers the interaction of the changing weather conditions and dynamic effect of the building design thus the ability of the building to attenuate external conditions is determined. The ESP program determined both the cooling energy requirements for north, south, east and west orientated zones in summer, see figure V and the heating energy requirements in winter for different facade glazing ratios (i.e. 75%, 50% and 25%) see figure VI. The initial cooling requirements shown in figure V provides the building designer with accurate information on which orientation has the most potential for natural ventilation and also the extent of changes which will be necessary to ensure natural ventilation will work for the high cooling load orientations. The information shown in figure VI allows the building designer to investigate the heating energy requirements in terms of peak load and also energy requirements over the day. The 75% glazing shows the largest peak load but no heating is required between the hours of 12 and 15 due to the solar energy entering the building through the windows and satisfying the heating energy requirements. The 25% glazing has a lower peak load but heating energy must be supplied in the afternoon.

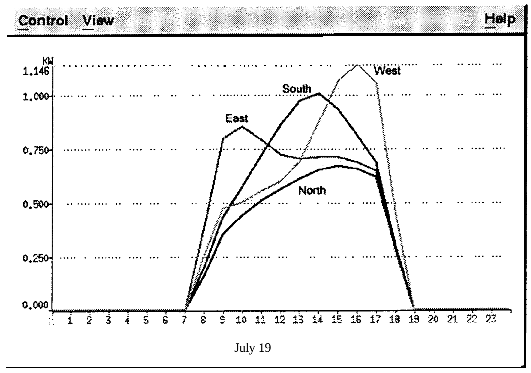

Figure V

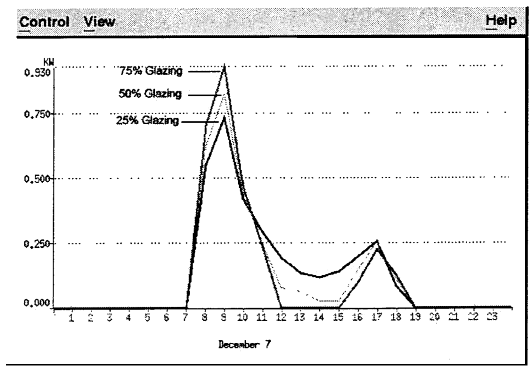

Figure VI

5.5 Total energy requirements

Figure VII shows the total annual energy requirements i.e. the energy required for lighting, cooling and heating. It is only when these three energy requirements have been optimised that the building designer can be satisfied that the building's impact on the environment has been reduced as much as possible.

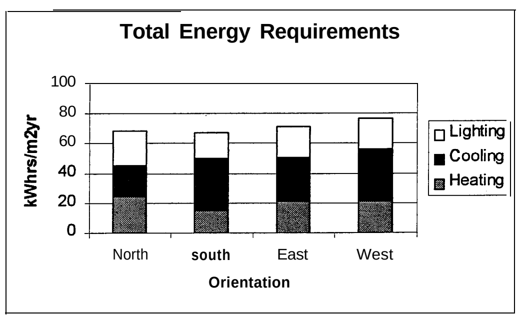

Figure VII

6.0 Green building temple bar

The Green Building in the Temple Bar area of Dublin was designed using the ESP, Macroflo and Radiance programs. The building is now occupied and is using 8 1% less energy and producing 64% less CO, than a conventionally designed building [4]. The ESP program allowed the correct evaluation of the dynamic effect of the building to modify the climate to be carried out, the Macroflo program ensured that the zones in the building could be naturally ventilated from the central atrium when required and the Radiance program was used to design the shape of the atrium and the position of the light-shelves to maximise the contribution of daylight to offset the requirements for artificial lighting. Maximising the building's energy performance and significantly reducing the energy demand meant that solar panels, photo voltaic panels and small wind turbines could provide the basis for a realistic energy system for the building.

7.0 Conclusions

The issue of sustainability will continue to be a problem due to population growth and increased demand for resources and energy. As buildings use up such a large amount of resources and consume so much energy a new design approach is needed. The invention. of electric lighting, central heating, lifts and air conditioning transformed people's expectations of buildings and expanded the range of what was possible in building design. Now there is the requirement for another shift just as radical in kind, in the development of building design for the sustainable environment. It will not be sufficient to take our existing designs and modify them to achieve an improvement in energy demands of say 15% to 20%. The building form, layout and orientation must be analysed using computer modelling to maximise the contribution the sun and wind can provide for heating, lighting and cooling the building. Using this new method the energy requirements and environmental impact of buildings can be significantly reduced. Materials should be selected which have low embodied energy values and whose production should not damage the environment. A great deal can be achieved by intelligent design using this new information but further research is necessary in collaboration with others to maximise this new design approach so that sustainable building design can be achieved.

Striving for Harmony between Contemporary Construction and Values of Natural and Cultural Heritage in Protected Areas

V. Stauskas
Vytautas Magnus University and Institute of Architecture and Construction, Kaunas, Lithuania

Absract
National and regional parks, natural preserves, landscapes for tourism and outdoor recreation etc., are protected areas. Often in the high density populated Western and Central Europe in these areas is contemporary living process and therefore construction. These are not strict natural reserves. Most of the buildings are residential and recreational.

Therefore the planning of the territory and construction should be in harmony and balance among these 4 interests: 1. Nature protection. 2. Preservation of cultural heritage. 3. Social interests of residents. 4. Holiday. -makers and tourists. Landscape specifics require that the new architecture in such zones would be managed. The main requirements: a) avoid large (high) structures vertically and horizontally; b) avoid locating the buildings on the sea shore or lake shore; c) uphold the visual priority of natural landscape; d) in the building shapes (especially roofs) and materials to consider the local architectural traditions. This example of approach in theory and implementation can be the policy of planning and construction in the Lithuanian southern sea coast, called Neringa (a peninsula of 52 km. Length, consisting of 5 townships - it is the Curonian Spit National Park). The Master Plan was approved in 1970 and 1994.

The variety of local landscape and ethnic traditions is shown in five Lithuanian national parks as well. Each park has his own “spirit”; it cannot be measured, but it must be felt. Architecture should give results that are synthesis of reason and emotion.

Keywords: Architecture, protected landscape, management, national park

Introduction

The most beautiful landscape and landscapes with special importance for science, recreation and tourism are often declared protected areas by law. These can be national or regional parks, or recreational areas of national or international importance. In contrast to American, African and Australian national parks, a rather intensive human activity and noticeable material traces of the post can be observed in national and especially regional parks of Western, Central and Eastern Europe. Buildings, their layout and architecture become here an important component of the landscape. In order not to okstroy the historically formed spacial and social harmony, it is necessary to seek balance among four main interest groups: 1. Nature protection; 2. Preservation of cultural heritage; 3. Social interests of local people and 4. Interests of holidaymakers and tourists. Theoretically, it seems quite obvious, yet in practice complicated and even conflicting situations may arise. Architectural management and some restrictions on building are necessary there.

Building Philosophy

A building is not an end in itself. Its primary goal is social, i. e. man: his life, work and recreation. Therefore, the architecture of a building is not "fine art" is "applied art". Secondly, a building is not "a thing per se" but "a thing in a certain environment". Both above - mentioned aspects are especially important in protected areas, mainly in the areas or recreation. On weekends and during holidays, people have different requirements for the overnight or public service buildings than for those meant for everyday work. These buildings are not goals but means for resting in a beautiful place with a landscape as natural as possible. The landscapes are usually very different. Traditions of social life are also different in different countries, they differ even in distinctive regions of the some country. The primary architectural principle in protected areas, therefore, is variety. No uniform ! The second principle is spacial harmony, not contrast. Architecture in protected areas is not a host but a guest. No matter how much we, architects and engineers, respect our work, it should not conceal the beauty and originality of the surroundings with its size, form and colours. A really professional project will catch the beauty of subtle nuances and harmony. The third principle is regionalism. Even modern architecture . should not be "fashionably cosmopolitan". Cultural peculiarities and evaluation of national identity as well as respect for it become important here. Regional specifics, as reflected in buildings or architecture of whole settlements, are also important as a tourist attraction and, consequently, as a factor in local economy.

Layout of Buildings in a Landscape

In protected areas one can usually find a historically formed network of settlements, villages and separate farms. As a rule, they are also protected and not liable to change. The location of an individual building in a historical village must conform to the tradition. A more complicated case is an intensive

World when hotels and restaurants practically “sit” on dunes and beaches while coastal parks are substituted by’ hoasts of advertisment boards. The famous Miami Beach and Atlantic City in the United States, and Gold Coast in Australia can serve as typical examples. The new continents could have learnt from mistakes of old Europe but they didn’t. Now we, the free Eastern European countries, have a chance in our integration process into the new Europe. This is what we trying to do and will continue doing.

Each sea resort should consist of two parts: day - time resort and night resort. Day - time surroundings should include vegetation, contact with sea and coast, sunshine and peaceful atmosphere. It should be minimally urbanized - small kiosks, pavilions and marinas. Night life emphasizes contacts among people, music and entertainment, discos, etc. Nature is not so important for the “night resort”. It should be, therefore, at least 200-300 metres from the coast. For a lake, the minimal distance is 100450 metres. Hilltops should be treated with caution not only in protected areas but in all recreational areas as well. New buildings should not only be avoided but also for fidden there because a natural silhouette can be easily destroyed, but it is impossible to reestablish it.

The same principles of harmony, variety and synthesis of interests that were mentioned in respect to buildings are also applicable to master plans of recreational areas including both private and municipal land. National and international importance of protected areas and main resorts is superior to private interests of individual persons. A clever person, no doubt, will be able to use these principles for the benefit of his own business.

Relationship between Ethnic and Modern Architecture

The preservation of ethnic architecture in protected areas, and especially in national parks, is obligatory and beyond all dispute. Sometimes the whole settlement or part of it is declared an ethnocultural or urban reserve, for example, the threee villages in the highlands Lithuanian National Park or the historical parks of Nida’s, Preila’s and Juodkrante’s fishermen villages in Neringa in the Curonian Spit National Park. Decayed buildings must be restored. They can serve as dwelling houses or small hotels. Such houses are especially popular among holiday makers. However, while building new hotels, the eternal problem of old and new come to the fore. In Lithuania, we try to keep to the following approach: a) new buildings in protected and recreational areas should not be high or big both vertically and horizontally. The most desirable size is that of a historical building; b) facades may be modern, but the most optimal choice is to use traditional construction and decoration materials; c) traditional roof silhouette is recommended, flat roofs are not built (thought in southern climate such roofs are quite acceptable).

For our general conception the northern, reserved atmosphere of Scandinavia and Finland, with an attempt to avoid cheap effects, is most acceptable. The ideas and works of Alvar Aalto, Ralf Erskin and other colleques are especially close to our understanding.

It is a pitty, but even in the Far East, with its old cultural values and deep

Island can serve as illustrations. The uniform appearance of Hilton, Sheraton and Intercontinental hotels is as irritating as Shell petroleum stations.

The Spirit of National Parks

“Spirit: this concept seems incongruous in the context of congress and serious audience of engineers, isn’t it ? But yes, it does exist; thought it cannot be measured, it can be felt. And architecture should give results that are synthesis of reason and emotion.

There are 30 regional parks and 5 national parks in Lithuania. And each of them, especially the national parks, has its “micro-spirit”. It comprises peculiarities of folk traditions, occupations of the people, nature, and contemporary mode of life. It is difficult to find right words to describe this, but let me try. For example:

The Curonian Spit National Park (Neringa)

Traditional fishing industry and forestry. In comparison with other national parks, the tourism industry is highly developed. The cultural heritage of Lithuania Minor, in particular the remaining timber architecture of Curonians’ villages. Water sports, especially yachting. An excellent sea life museum in Smiltyne. Scientific conferences in winter. Unique dune landscape. The “spirit” of the sea and sand.

The Samogitia National Park

Farming is the traditional occupation. Rich rural and religions architecture. A religions centre in Samogitian Kalvarija. Folk handicraft and folk festivals. A museum of former Russian missile base: The “spirit” of folklore prevails.

The Highlands National Park

More lakes than in other parks. Traditional occupations - farming, fishing and forestry. Old timber architecture villages are unique to this national park. A lake tourism centre. A bee museum. Holiday - making in villages is popular. The “spirit” of lakes and old villages.

The Dzūkija National Park

A landscape of great woods and rivers. The valleys of the Nemunas River and small rivers. Traditional occupation - forestry. The “capital” of mushrooms. The local people are known for their ethnocultural peculiarities and folklore. Historical places Liskiava and Merkine. The “spirit” of huge pine forests.

The Trakai Historical National Park

It is the place of three castles that have historical significance for Lithuania. A unique restored castle - museum on an island. Intensive tourism . The relict Karaim ethnoculture. Festivals of ancient music. Water sports. The “spirit” of old Lithuanian history.

To have a subtle feeling of national parks’ “spirits” is a difficult but obligatory task for designers, architects and engineers. Interesting differences may give new and unexpected ideas that will reveal themselves in the architectural layout of buildings and organization of open spaces.

Experience of the Curonian Spit National Park (Neringa)

It is a long (100 km) Sandy peninsula (52 of which belong to Lithuania) between the Nemunas delta, the Curonian Lagoon and the Baltic Sea. Both the Lithuanian and the Russian parts of the peninsular are national parks. A unique dune landscape (60-65 m high). There are four old fishermen villages in the Lithuanian part: Nida, Preila, Pervalka and Juodkrante as well as Smiltyne weekend recreational area in the very north, near Klaipeda city and port. In 1968-1970 and 1993-1994 master plans and detailed plans for all territory and every village were made for this area. Tourism management and development programme, reglamentation of architecture, nature and cultural heritage protection programme, suggestions for optimal social and development are all meant to preserve and maintain this national park. The population of Neringa is **2,** 6 thousand, in summer they cater for up to 5-6 thousand holiday makers and tourists every day. According to functional and ecological zoning (based on the permissable protective regime), over 66 % of the area are landscape reserves and preserves, about 30 % are recreational areas by the sea and the Curonian Lagoon.

Settlement management as well as building policies seek to implement the philosophy and theoretical principles prepared by the Institute of Architecture and Construction in Kaunas which were presented at the beginning of the article. After World War II, with changes in population and a great influx of holiday makers (esp. from the East), a number of new buildings were built and numerous old houses restored. At present practically no house is higher than three storeys, no ferro- concrete structures were used. The first flat roofs are now being replaced by slanting tile roofs. There are a lot of timber or combined brick and timber facades. One can still feel the "spirit" of the villages of the ancient Curonians. Traditional water occupations and water sports have been preserved.

Yet, there have also been mistakes. The historical hotel "Jurate" in Nida as well as new of "Santauta" and "Azuolynas" hotels in Juodkrante are too big. There is a dangerous tendency towards cosmopolitan commerce felt in the new municipality that organizes "Rock music shows" and motor rally races. Intentions are even voiced to built a new bridge and airport establish the Casino. We are of the opinion that the task of architecture professionals is not only to make a master plan as a guideline for the municipality but also to continue our elucidating and humane mission all the time. The idea of harmony and balance will be crushed if only side of interests will be accentuated. To preserve the uniqueness and "spirit" of the place is important not only for us but also for the whole World. On the threshold of the 21 st century we say: "Let's advance ourselves !"

Conclusions

The tasks of land use and land management in protected areas are much wider than just relations between buildings on the side and nature and cultural values on the other. They have been shortly discussed in the present article. On the whole, it is worthwhile to remember the new definition of architecture adopted by the International Union of Architects (IUA) in Warsaw in 1981 more often. Instead of the old statement: "Architecture is the art of construction "it is said now: “Architecture is the art and science of shaping environment”. A building is just one element of the environment. The responsibility of architects and engineers in creating this element has, therefore, been growing. The 21 st century is the century of sustainable development. The ideas and principles applied at present in protected areas will become more and more useful in all areas as well.

Persistence of Energy Savings of the UK's Energy Efficiency Best Practice Programme for Buildings

S. P. Boyle
Impact Assessment Unit, BRECSU, Building Research Establishment, Watford, UK

Abstract
The Energy Efficiency Best Practice Programme is the United Kingdom's independent information dissemination programme on energy efficiency and was established in 1989. The programme is jointly managed on behalf of the Department of the Environment, Transport and the Regions (DETR) by the Building Research Energy Conservation Unit (BRECSU) and the Energy Technology Support Unit (ETSU). BRECSU, part of the Building Research Establishment, is responsible for energy efficiency in buildings whilst ETSU is responsible for the programme's industrial processes component. This paper is concerned solely with the buildings element of the programme – referred to as the EEBPP throughout. The aim of the EEBPP is to advance and spread ways of improving the efficiency with which energy is used in UK buildings. Under the programme information on energy use and energy saving measures is gathered and disseminated through publications, workshops and other events. Annual assessment is made of the total energy savings resulting from the programme including, in particular, its influence in each of thirteen building sectors in which the programme is active. To date energy savings have been cumulatively added, year on year. However, now that the programme is relatively mature, it is important to account for any lack of persistence/sustainability of energy savings that may occur in practice. It is generally accepted that the persistence of savings attributed to energy conservation programmes is difficult to monitor and evaluate due to the numerous variables that affect the reliability of savings and the practical challenges to measuring these variables. This paper reviews the international research of persistence of savings in energy conservation programmes and discusses a recent initial study for specific application to the UK's EEBPP. The study resulted in the development of a matrix system of standard persistence factors. These factors relate the frequency of occurrence and the severity of the reduction in persistence. One factor is selected for each measure and for each particular building sector for each year of the EEBPP impact assessment. Although the values are tentative at this stage, due to the lack of research in this field, the study has resulted in a system which can now be applied to the programme's cumulative savings and thus start to take account of persistence effects.
Keywords: Energy efficiency, impact assessment, persistence, sustainability.

1 Background to the study

The Energy Efficiency Best Practice programme for Buildings (EEBPP) is managed by BRECSU (the Building Research Energy Conservation Support Unit) on behalf of the UK's Department of the Environment, Transport and the Regions (DETR). The programme is the UK's largest information dissemination programme for buildings, with an annual budget of around £7M. The programme aims to:

- Generate information on new and proven techniques for reducing energy use in buildings, establishing what represents good practice
- Present information in different forms for different target audiences
- Disseminate guidance to all target groups through documents, seminars, workshops, etc.

In order to measure the effectiveness of the programme in stimulating real energy savings, BRECSU has developed an impact assessment methodology for the programme and undertaken an annual impact assessment survey every year since the programme's inception in 1989. Essentially this establishes what energy saving measures have been installed in buildings in each sector through clear influence of the EEBPP. Results so far estimate the cumulative primary energy savings to the end of 1996/7 at 86PJ/year, compared to the programme's current target of 1 10PJ/year by the end of the year 2000.

In producing cumulative savings, measures installed in a particular year are assumed to continue to deliver the same savings each year thereafter. As the programme matures, it is necessary to recognise that, for many measures, this is an over-optimistic assumption. Savings in fact are likely to reduce over time. This is the concept known as the persistence of energy savings. This paper details the initial study into the issue of persistence and raises questions which are likely to require further investigation.

2 Definitions

One problem is that the term "persistence" gets used in many senses: the whole concept ie the persistence effect; or the attribute of a particular measure. So that when you say 'persistence decays', you are using the term differently to 'persistence is the phenomenon under which energy savings vary over time'. Service life is only one aspect affecting the persistence of energy savings.

2.1 Persistence

As the purpose of this study was to develop a methodology that could allow persistence to be taken into account in the EEBPP's impact assessment analysis, it is essential to be clear on what is meant by the term 'persistence' in the context of this study. For this study 'persistence' means 'sustaining the level of energy savings produced by the energy conservation measures installed as a direct result of the EEBPP, as identified by the programme's annual impact assessment'. Impact Assessment of the EEBPP involves estimating the likely realisable energy saving produced by measures installed as a direct result of the programme. The savings analysis therefore accounts for non-ideal aspects of installation and operation ie that the full technical potential for savings is unlikely to be realised. Persistence issues apply to energy savings produced by the energy conservation measure from the post-installation stage onwards.

For example, lack of persistence includes:

- Known effects of intrinsic deterioration of energy efficiency where this reduces the level of efficiency used for the initial energy saving calculation (eg Argon gas leaking from double glazed units over time)
- Reductions in efficiency due to changes in management, maintenance and use post-installation.

However, persistence does not include:

- Nationally applied changes in the periods and intensity of use of energy saving measures (eg longer opening times) or annual variations in the area of application of the measures (eg different floor area figures due to closing of classrooms or wards) as these are currently taken into account
- Reductions in efficiency due to normal standards of manufacture, design, installation, commissioning, management, maintenance and use (normal standards can be expected to be less than perfect and only normal levels of energy saving will have been taken into account when setting the levels for calculation in the impact assessment)
- Intrinsic deterioration of energy efficiency that is normally allowed for in design calculations (eg gradual light output reduction of fluorescent lamps).

2.2 Service life

The study recorded the service life of measures where the information was available, although this is not the whole picture and only one issue affecting the persistence of energy savings. If an item reaches the end of its service life and is replace by a similar item, the saving of energy will not be affected. The service life does affect the estimates of persistence of energy savings, however, in cases where:

- The item is not replaced at the end of its service life (eg heat recovery wheels)
- The replacement is less efficient (eg ordinary air filled double glazed units replacing argon filled low emissivity glass units)
- The replacement is more efficient (eg new beer chiller systems rather than the recommended old systems currently being installed in many pubs).

3 Practical issues related to persistence of energy savings calculation

3.1 Relevance and availability of data

An accurate measurement of persistence is very difficult. It requires measurements to be made over a long period during which other things, that might upset the measurement, remain static (eg measurement can be upset by different use of spaces, by changes in equipment and security measures or even by growth of sheltering trees). Researchers have generally avoided this area because of the length of time required for research projects; they are wary of the constantly changing conditions and the large number of variables found in practice.

Besides being difficult to measure, there is a positive disincentive to make measurements. Manufacturers and organisations promoting energy saving do not generally want to publicise decay in persistence in products, few developers want to know about the decline in performance to be expected after the building is handed over. The difficulty of carrying out research and some reluctance to investigate persistence have resulted in a lack of data. In many cases this study has had to rely on anecdotal information and assumptions.

3.2 Basis for EEBPP calculation of energy savings

The EEBPP impact assessment for 1996/7 was based on an assessment of savings made in 13 building sectors by **71** energy savings measures recommended by the programme (not all measures apply to all buildings). Every year the survey collects data on the floor areas to which each of the measures has been applied during the past year. The calculation of energy savings is based upon grossing up to the national stock based upon floor areas. The basis for savings calculated from a particular measure may vary from year to year to account for:

- Changes in regulations (only measures above the baseline provided by regulations or 'standard' practice are counted)
- Changes to the floor space within each building category (eg transfer of social to private housing or closure of hospital wards)
- Number of contributing measures (to ensure that added values are reasonable)

In assessing the savings allowance is made for some of the practical issues that, in real life conditions, reduce the theoretical savings that could be achieved. These issues include:

- The finding in previous surveys that not all improvements in energy efficiency result in energy savings (eg occupants preferring the 'comfort' of warmer rooms rather than all the potential fuel savings from energy measures being realised)
- Normal standards of installation and maintenance (recognising that many measures will not be installed and maintained in a way that achieves maximum efficiency)
- Normal standards of use and management (recognising that use and management often fail to optimise the potential savings from measures).

The calculation of persistence must start from where the impact assessment assumptions stop eg if the analysis assumes monthly cleaning of filters in a ventilation system then annual cleaning could make the system less efficient and would represent a lack of persistence. Therefore the assumptions underpinning the energy savings estimates must be recorded.

4 Working method

4.1 General approach

The study had a number of phases:

1. Literature review of published information on the persistence of energy savings
2. Investigation of persistence issues related to the measures included in the EEBPP's impact assessment, including numerous contacts with manufacturers, building professionals and researchers
3. An investigation into the persistence of energy savings in one building category – health care
4. Development of a method to account for the lack of persistence, for application to the EEBPP's impact assessment
5. Extension of the study to suggest how the method should be applied to all EEBPP building categories.

4.2 Study of previous work on persistence

A literature review showed that almost all references to persistence in the use of energy and buildings were from North America and related to electricity supply policies. Enquiries about persistence of energy savings from building research organisation in Scandinavia, Australia and Japan drew a blank. When the study was explained to one set of research staff who were preparing and issuing guidance on energy saving, said "well, we wouldn't want to know about that – it would threaten our funding". Subjects related to persistence, such as deterioration in thermal performance, were available from some sources in the UK and abroad.

In the UK the Chartered Institution of Building Services Engineers (CIBSE) has embarked on the updating of its 10-40 year old figures for service life. Reliable data in life expectancies are seen as important supporting information in demonstrating the feasibility of a project and potential cost savings.

4.3 Gathering information on measures

In addition to consulting EEBPP publications and others giving guidance and experience on measures, information was gathered from researchers, managers, manufacturers and others on the practical issues related to testing, installing and operating measures.

4.4 Investigation of persistence in health care buildings

In order to develop a methodology for assessing persistence, one building sector was initially chosen for detailed investigation – NHS-Trust buildings. The study involved:

- A study of the EEBPP package of Good Practice Case Studies and Guides on health care buildings and other relevant published material
- Consultation with the EEBPP health care manager, with the Department of Health and with several consultants working in the health care category
- Consultation with seven NHS Trust energy managers.

The aims were to:

- Find whether the managers had evidence of lack of persistence
- Seek reaction to suggested persistence factors relevant to health care
- Gather information on energy management
- Discover the place and status of energy saving within the sector

4.5 Development of a method to account for lack of persistence

A method was chosen that would provide a means to account for the lack of persistence that could take account of whatever data was available without suggesting unrealistic precision. The method would then allow adjustment of impact assessment savings for previous years, whilst allowing the basis for these adjustments to be seen and for changes to be made as additional data becomes available.

4.6 Extension of the study to all building categories

Following development of a methodology for health care buildings, it was widened to incorporate all 13 building categories and developed in order to provide decay factors for a period of 15 years.

5 Findings related to measures

5.1 Persistence of measures generally

No regular pattern of persistence decay was found – each measure must be considered on its own and often in the context of different building categories. Decay does not occur regularly over time. It may be more rapid at first or speed up towards the end of service life, as happens with swimming pool covers. Commonly, however, decay affects measures at a particular time eg when a building is refurbished or when an energy manager is removed.

5.2 Changing views on persistence in North America

There is a wealth of American material on this subject, which cannot be adequately covered in a few paragraphs. However, a 1992 paper by Edward Vine [1] provides a good starting point. It presents a conceptual framework for analysing persistence of energy savings, summarises the limited experience of what was known, and provides guidance for retrospective and prospective studies, suggesting strategies for both conducting research and developing policies and mechanisms to help ensure the persistence of savings.

In American studies, persistence has a wider meaning than in this study, because the North Americans have been concerned with energy saving programmes where approvals are sought at the design stage and lack of persistence can also occur between the initial approval of a proposal for saving energy and what is actually installed, while this study only looks at persistence in relation to installed measures.

Throughout the 1980s, persistence of energy and demand savings became important to many stakeholders. Resource planners needed to know if the energy saved through energy efficiency programmes was off-setting generating resources. Utility shareholders needed to know if financial incentives based on measured energy savings were continuing. At the time of the Vine paper, persistence of energy savings was probably the single largest, unanswered question in the consideration of 'Demand Side Management'. It was assumed to be relatively constant and most analyses of persistence relied on engineering estimates of measure life. The limited empirical research, at this date, raised questions about the validity of using manufacturer's claims for physical measure lives. To answer the above questions and concerns, researchers have focussed on: exploring evaluation techniques, gathering case data, teasing out relevant influences on persistence, and developing realistic models for everyday use.

The introduction of competition in the USA has shifted areas of interest to parallel those in the UK. International accords such as that at Rio have heightened the importance of being able to accurately include the persistence of energy measures contributing to national CO_2 reduction programmes. Vine identified two dimensions of persistence, which most subsequent papers have taken up: Measure lifetime and operation, and total and net Programme energy and peak demand impacts. These are inter-related in that Programme persistence includes Measure persistence, as well as other factors. This paper was valuable in ascribing equal importance to technology and behaviour. They both affect persistence, they often interact, and they are difficult to separate, particularly behaviourally – dependent measures such as cleaning refrigerator coils and resetting HVAC time clocks, to accommodate occasional unplanned occupancies. As the field has been explored in greater depth so the ideas that simple solutions would be found have receded. For instance, reasons for a lack of persistence were cited by Hicks [2] as not solely about measure failure but related to market factors – remodelling cycles, operational factors and technical degradation.

6 The results of the UK study

6.1 Application of persistence factors to building categories generally

The persistence of measures will vary between building categories. For example, when compact fluorescent lamps are used within housing it is estimated that a large proportion of them will be replaced with tungsten lamps (this is supported by retail sales figures and is probably due to unfavourable customer reaction to the appearance and the-delayed start up of energy efficient lamps). Building categories vary- in three respects:

1. Their construction; eg categories such as offices, with fully glazed facades have more need of shading and cooling than new housing
2. Their management; eg buildings with sophisticated equipment and control systems require management that is capable of optimising their operation
3. The way they are used; eg measures installed in buildings that are in continuous use can produced greater savings than in buildings of the same floor area that are only used occasionally.

Each of these variables must be taken into account when assessing persistence factors for both new and existing buildings.

For some measures refurbishment or change of use is likely to affect persistence because the measures may be removed or made less effective by alteration work or change of usage (eg heating zone controls when the building is differently subdivided, point of use water heaters when sanitary facilities are rearranged, or energy policy when a new firm takes control of the building). It follows that the shorter the period to refurbishment in a particular building category, the greater the likelihood that persistence will decay. In the UK approximately 4% of the total building stock is refurbished each year, although there is a wide variation in the periods of refurbishment even within the same building category.

6.2 Application to health care and other building sectors

Details of application of the methodology to the Health Care sector will be presented at the conference. There is not space for a detailed summary here. However, detailed investigation of and consultation with representatives within this sector enabled a matrix system of standard persistence factors to be developed. These -factors relate the frequency of occurrence of decay in energy saving over time and the severity of the reduction in persistence. One factor is selected for each measure and for each building sector for each year of the EEBPP impact assessment, making 887 persistence factors for 1996/7 alone. These factors have been developed for a period of 15 years, allowing retrospective application to the EEBPP and some forward application in years to come.

7 Conclusions

This study has developed a systematic means of accounting for any potential lack of persistence of EEBPP savings for all 13 building sectors promoted by the programme. The factors consider energy savings post-installation. Therefore future impact assessment of the EEBPP will include the following persistence methodology:

1. A base figure of the energy expected to be used in a typical building of a particular category
2. The potential savings that could be expected from the introduction of measures under ideal conditions

3. The saving that is likely to be achieved in real conditions (based upon 2 but taking account of design, installation, maintenance and use)
4. The annual savings that can be expected when factors related to changes in savings over time are included (including deterioration of products, downgrading of management staff and different uses for part of a building)

We are some way towards this ultimate system, but it must be noted that the lack of data on performance of energy measures over time means that the persistence factors can only be tentative without more research. Nevertheless, we have developed a system which can now be applied to the programme's cumulative savings and start to take account of persistence effects.

An environmental perspective on UK construction materials

L. Parrott,
British Cement Association, Crowthorne, United Kingdom

Abstract
The environmental effects of UK construction and construction materials are reviewed in an attempt to assess their importance for research, development and UK sustainability. Usage of construction materials, floor areas, energy use and emissions to air are examined but many assumptions are necessary to extract construction-related components from national environmental statistics. It is shown that in-use and transport contributions from construction are major components of national impacts, particularly with regard to energy use for thermal comfort in buildings and the transport between buildings of people and goods. In relation to the cumulative, long-term influences of urban planning and transport, energy efficiency associated with building design, durability and reuse of buildings, the direct role of materials manufacture is currently of lesser significance. It is concluded that an improved assessment of sustainability for construction and construction materials requires research to determine a set of environmental indicators for construction and analysis methods wherein technical results can be transparently evaluated from a representative range of alternative viewpoints. Research on construction materials should be aimed at facilitating the life-cycle analysis of environmental impacts over the design, supply, construction, use, refurbishment, repair and disposal stages of the life cycles of alternative structures so that the best practicable options can be determined for a specific suite of environmental issues. The software tools and databases should permit incorporation of life-cycle analyses into routine construction planning and design. With regard to the sustainability of the UK's energy consumption, future environmental research should examine and stimulate the integration of construction with the provision and use of renewable energy.
Keywords: Buildings, construction materials, emissions to air, energy, indicators of sustainability, transport.

1 Introduction

This paper introduces some general environmental issues for construction, outlines policies, summarises construction materials usage and environmental effects and provides an environmental perspective for construction materials in relation to other construction sectors, UK environmental performance and research strategy. It is emphasised that many assumptions were needed to extract construction-related components from national statistics [1-7]. The **costs** associated with the control of environmental impacts and the **value** of the corresponding environmental improvements are important issues for a sustainable strategy but they are not addressed; the analysis tools are still being developed and information is sparse. A recent European Community proposal aims to accelerate its sustainability programme by actions relating to climate change, ozone depletion, acidification, waste, noise, transport and energy and other organisations also highlighted these issues [1-7]. Sectors such as building owners, building users, designers, builders, educators, investors, insurers, lawyers, environmental pressure groups and the public can have additional environmental concerns [1].

The incorporation of a formal environmental component into construction design is becoming increasingly necessary and should be based upon a holistic life-cycle analysis to determine the best practicable environmental option wherein the designer identifies those materials and components that most effectively complement his designs. Design tools should not require over-simplistic, preliminary environmental screening of materials; this could restrict the development of some effective and innovative design options. The location of a structure relative to the sources of materials and components from which it is built will influence environmental burdens arising during early life-cycle stages. More importantly its location relative to those of its users and suppliers will influence the burdens accumulated over the lifetime of a building. The effects of heating, cooling and ventilation also accumulate over the lifetime of a building to constitute a major component of its environmental impact. All of these impacts should thus be analysed in an environmental component of design.

Within a given set of environmental analysis boundaries there is a range of possible analysis conventions and assumptions; the current state-of-art is insufficiently advanced for general agreement although IS0 is currently attempting to develop preliminary LCA standards. Alternative sets of conventions and assumptions for a specific building could lead to significantly different outcomes from environmental analyses (even though the actual environmental impacts remain fixed). Sensitivity analyses are needed to demonstrate the influence of the alternative analysis conventions advocated by different sectors and thus promote constructive debate. UK government departments have recently initiated the development of environmental satellite accounting to link market activities with their impacts upon the use of natural resources, degradation of the environment and the cost of activities designed to mitigate these impacts [3]. Pilot studies [8] examined atmospheric emissions, along with economic indicators, categorised by industry, fuel and transport mode; mitigation expenditure was about 0.6% of sales.

2 Construction materials

This section briefly indicates the quantities of materials used in UK construction, the energy associated with their manufacture and the associated emissions to air. Diverse source of UK data were reviewed to compile Table 1, [1] so only broad conclusions can be drawn. The data include transport to the UK; transport within the UK is covered separately. It was found that no single material was dominant with regard to energy use; indeed the initial six groups of materials each contribute between 7 and 18% of the construction materials total. The remaining group (gypsum products, glass, asphalt, mineral insulation, plastics, paints, adhesives and sealants) account for 24% of the construction materials total. Construction materials are used in substantial quantities (291 Mt) but 'the associated energy constitutes only 6.1% of the total UK delivered energy [1,2]. If allowance is made for differences in populations the total quantity of construction materials used in the UK appears to be virtually the same as that used in Denmark [1].

The emissions to air associated with the manufacture of construction materials range from 4 to 13% of UK releases and are significant enough that they should be included in assessments of UK sustainability. Information on fine particulate and heavy metal emissions were limited although they may prove to be critical for the construction materials industries. The major portion of emissions shown in Table 1 derive from the initial six groups of materials; this is due to the large quantities that are used. The first five tabulated material groups are closely connected with mineral extraction; however, the bulk of raw materials extracted in the UK are geologically abundant and involve only limited transport burdens. A qualitative assessment [1] suggested that the following parameters were also of environmental significance for construction materials: material depletion, manufacturing wastes, transport impacts, land use, heavy metals, chlorides, fluorides, VOCs and land pollution.

Materials	Carbon dioxide (Mt)	sulphur dioxide (kt)	Nitrogen oxides (kt)	VOCs (kt)	Carbon monoxide (kt)	PM10 (kt)	Delivered energy (PJ)
Aggregate/stone	3.85	15.66	64.2	18.7	37.5	?	41.8

(% of UK)	(6.8)	(5.6)	(10.4)	(4.2)	(13.0)	(>4.4)	(6.1)

Table 1 Materials inventories per year for UK construction

3 Environmental significance of structures

This section illustrates energy usage and other environmental effects of structures during their operational period and compares these with the effects arising from construction materials. The energy use for the construction phase is about 54 PJ/year [1]; those for the demolition and disposal life cycle stages are thought to be smaller and are not considered further. The range of structures considered is intentionally broad in order to ensure that construction factors which afford the greatest control of environmental impacts are identified. The energy data in Table 2 are from a wide range of sources [1] and should be regarded as approximate.

There are about 21 million properties in England and Wales so the provision and use of buildings were expected to be major contributors to national environmental impacts. Transport structures such as roads, rail track and bridges, together with passenger and freight requirements are associated with an increasing, transport-related environmental burden. Over the last 20 years there has been an increase of about 50% in fuel usage for passenger and freight road transport [2]: apart from traffic congestion and consumption of petroleum fuel there is an associated burden on urban air quality due to vehicle emissions. The energy consumptions of the passenger and freight transport sectors in 1994 were about 1173 and 503 PJ, respectively [2]. The planning, location, design, construction and operation of transport structures offer an element of control over such environmental burdens.

Most electricity in the UK is currently generated by burning fossil fuels [2]. The recent shift from coal to natural gas burning has reduced polluting emissions to air. The main technologies for renewable energy are wind, waste combustion, hydro-electric, wood fuel, anaerobic digestion, landfill gas and solar [4]. Wind, hydro-electric, wood fuel and landfill gas technologies use substantial areas of land or water and this could limit their application. Indeed there are few remaining sites that are suitable for hydro-electris schemes, which account for 92% of renewable energy in Europe. Biomass and wind-power have increased in recent years and account for about 7% of UK renewable energy. Construction schemes that generate energy from tidal and wave movements have been advocated when there is a parallel construction need for protection against coastal erosion but such energy appears to be significantly more expensive than that generated using conventional methods. Generation of electricity from photo-voltaic panels is

Indicator	UK Total	Construc. materials	Construc. process	Buildings in use	Dwellings in use	Transport	Other sources

Table 2 Selected environmental indicators and construction-related contributions

minimal at present but its use in connection with the cladding of buildings and transport structures seems likely to increase [1]. There is much scope for combining renewable energy generation and construction schemes and this would help to raise the 0.5% renewable component of UK energy towards the 5% European figure. There are a several points that emerge from the energy data in Table 2:

1 - energy associated with the provision and use of structures and buildings accounts for about 77% of UK final energy: excluding transport the figure becomes 51%.

2 - energy associated with construction materials accounts for about 7.9% of the construction energy (provision plus operation): excluding transport the figure becomes 11.9%.

3 - improved construction planning and design could substantially influence material, operational and transport energy use and, by implication, UK environmental performance. Provision and use of housing plus transport account for about 60% of UK final energy and should be primary research targets.

4 - an analysis of construction materials usage by type of structure would help manufacturers to anticipate the implications of increasing environmental stringency in specific construction sectors.

Much UK energy use arises from the operation of, and the transport of people and goods between, buildings. An element of control is exercised via planning requirements relating to new housing but, in spite of more onerous thermal efficiency requirements, UK domestic energy consumption has not greatly diminished. Possible additional methods of mitigation are: encouraging refurbishment of existing dwellings and other buildings to improve thermal efficiency, stimulating mixed building redevelopment to reduce travel and setting rebuilding targets to reduce the energy consumption of the UK construction stock. Energy self-sufficiency does not seem beyond current technology, although it is difficult to justify with current economic reasoning. Unfortunately methods and tools do not yet exist for a wide-ranging best-option analysis of the interacting environmental effects arising from housing, buildings, industrial processes and the transport of people and goods.

Table 2 includes emissions that relate to the greenhouse effect, acidification and air quality. The selection of indicators was partly influenced by the availability of data and, in developing an environmental research strategy for construction and construction materials, it would be desirable to examine additional factors, including those from recent UK listings [2]. The UK's Foresight Construction Panel is currently canvassing views on a set of key sustainability indicators for buildings; it has yet to consider civil engineering structures, renewable energy structures, transport or urban planning. UK and international air emissions data [5,6] were used to assess construction-related contributions to emissions of carbon dioxide, sulphur dioxide, nitrogen oxides, volatile organic compounds (VOCs), carbon monoxide, PM,, particulates, and heavy metals.

The total UK carbon dioxide emission for 1994 was 548 million tonnes; the portions attributed to domestic and transport sources were 149 and 145 Mt [1,5]. The portions attributed to buildings in use and the construction process were estimated from the domestic source, adjusted for relative energy uses. The carbon dioxide emissions for construction materials and other UK sources were estimated from the UK total minus those from domestic and other buildings, the construction process and transport; this residue was allocated in proportion to energy use with the proportionality constant being process-dependent [5]. A better approach would be to assess emissions based upon measurements for construction material processes but such data are not currently available. The carbon dioxide emissions from construction materials corresponds to about 7% of the UK total, whereas those from dwellings and buildings amount to 41%.

The emissions in Table 2 for sulphur dioxide, nitrogen oxides, volatile organic compounds (VOCs), carbon monoxide, PM,, particulates, and heavy metals were estimated using an approach similar to that adopted for carbon dioxide. The differences of their distribution between sectors for the various environmental indicators arises from the differing characteristics of transport, process and fuel use. The energy and carbon dioxide data in Table 2 were discussed in May 1997 with researchers from Finland, Denmark, Netherlands, and France [1]; there was fair agreement between countries regarding the portions of national energy use and carbon dioxide emissions attributable to different sectors; construction materials - 5 to 7%, buildings in use - 40 to 50% and transport - about 25%. However, parallel data on other environmental parameters, such as sulphur dioxide, nitrogen oxides or VOCs, were not available for comparison.

The estimates in Table 2 are shown in brackets as percentages of UK totals. Energy approximatelv reflects carbon dioxide emissions but it would slightly over-estimate the national influence of construction materials for sulphur dioxide and VOC emissions and under-estimate their influence for nitrogen oxide, PM,,, heavy metal and carbon monoxide emissions. With regard to buildings and dwellings in-use energy approximately reflects national carbon dioxide and sulphur dioxide emissions but it would over-estimate their effects for other emissions. Even within the sectors buildings in use, dwellings in use, construction process and construction materials energy did not appear to be a reliable proxy for other environmental indicators. It can be argued that construction design and planning significantly influence transport emissions as well as those deriving from dwellings in use, buildings in use, construction process and construction materials. Since the individual emissions from these sectors, with the exception of heavy metals, constitute 52 to 98% of UK totals it is evident that construction research should, with some urgency, explore how design and planning might contribute to improving the UK's environmental performance and sustainability.

It is evident that factors such as initial design, in-use operation, building location, durability of the building and refurbishment strategy are likely to impose larger environmental effects than the particular construction materials selected for construction. However there is a shortage of case studies for different types of construction from which firm conclusions can be drawn. Ideally case studies would quantify environmental effects at each life cycle stage, from materials extraction through building operation to recycling; they would also include sensitivity analyses relating to assumptions. Such case studies would help clarify research directions and would indicate proportionate levels of research and development support that could be expected from different sectors of the construction industry.

4 Concluding remarks

The environmental effects of UK construction and construction materials have been reviewed in an attempt to assess their importance for research, development and sustainability. Many assumptions were necessary to extract construction-related components from National environmental statistics. In-use and transport contributions from buildings and structures are major components of national environmental impacts, particularly with regard to energy use for thermal comfort in buildings and the transport between buildings of people and goods. In relation to the cumulative long-term influences of urban planning and transport, energy efficiency associated with building design, durability and reuse of buildings, the direct role of materials manufacture iscurrently of lesser significance. However the balance may shift if environmental impacts become more heavily penalised, the energy efficiency of buildings improves and construction projects incorporate renewable energy generation. This assessment of the importance of construction is echoed in reports from Building Materials Producers, the Construction Industry Council, the Foresight Construction Panel and others [1].

Research is required to develop a set of construction indicators (environmental, social and economic) and analysis methods wherein technical results, of high integrity, can be transparently evaluated from a representative range of alternative viewpoints so that the roles of construction and construction materials in UK sustainability can be more accurately assessed. Research on construction materials should be aimed at facilitating the life-cycle analysis of environmental impacts of buildings and structures over the procurement, design, supply, construction, use, refurbishment, repair and disposal stages of the life cycles of alternative structures so that the best practicable options can be determined for a specific suite of environmental issues; such holistic tools would obviate the need for over-simplistic, preliminary screening of materials. The software tools and input databases should permit incorporation of life-cycle analyses into routine construction planning and design.

Environmental research should examine and stimulate the integration of construction with the provision and use of renewable energy; this would also create market opportunities for associated technology, plant, consultancy and construction management. Energy use did not appear to be a direct proxy for other environmental impacts such as sulphur dioxide, nitrogen oxides, carbon monoxide, fine particulates and heavy metals. The selection of boundaries and conventions for analyses can significantly affect the outcome and, until better understood, they should be the subject of sensitivity analyses. The environmental outputs from initial research and from subsequent analyses of buildings and structures should be formulated as inputs to national environmental statistics and accounts: they should also be compared with current typical and good practice benchmarks to stimulate improvement.

The benefits of the proposed, broad research and development strategy would be felt at several levels: the effects of construction and construction materials upon UK environmental accounts would become clearer and more amenable to control. It would also provide a framework within which adjustments to the extent and balance of regulation could be assessed for their likely influence upon UK environmental performance and sustainability, an improved perspective on the relative influence of the construction materials sector would highlight critical subject areas, suggest performance benchmarks and indicate an appropriate level of contribution to environmental research. Furthermore there would be encouragement to make more accessible the existing environmental information that has been collected for regulation of pollution and the construction industry would gain additional support from the public and environmental activists, if seen to be promoting improved environmental design and sustainability via appropriate enabling research.

It can be argued that the barriers to the quantitative evaluation of environmental impacts in construction design are so large that a consensus cannot be reached. However the trends within UK Government departments and in other European countries are towards a satellite environmental accounting system in which the environmental impacts are expressed in appropriate physical units and are evaluated using currently appropriate weighting systems [1]. Such an approach enables environmental issues to be given due consideration in assessments of sustainability while allowing alternative evaluation philosophies to be transparently illustrated. Public and government opinion will soon demand environmental assessment in construction: the industry, including its institutions and standards organisations, should participate in and shape development rather than await or oppose it. National statistics are needed on the usage of construction materials and the stocks and energy performance of buildings and structures. These data are essential for setting benchmarks for the environmental performance of construction materials, components, buildings and structures. Where recent data are commercially sensitive then results from a previous year would probably suffice. Environmental standards tend to improve so there would be an inbuilt incentive to supply the most recent data that is consistent with commercial interests.

The Limits to Sustainability

Charles J. Kibert,
University of Florida, Gainesville, Florida 326 1 l-5703 USA

Abstract
The many worldwide sustainability efforts and movements allude to two distinct but potentially conflicting goals: (1) leaving adequate resources and environmental quality for future generations, and (2) providing for developing countries to create healthy economies that allow their populations to experience a quality of life better than mere survival. Without rapid, dramatic increases in resource efficiency, huge reductions in waste and pollution production, stabilization of population, international accords that limit the production of greenhouse gases, and widespread protection of natural areas for their function and biodiversity, sustainable development will be nothing more than a grand illusion. This paper examines these issues and provides some conclusions about sustainable development in general and, more specifically, about the impacts on the built environment.
Keywords: Sustainable Development, Ecosystems, Resource Efficiency

1 Introduction

The concept of sustainable development is much in vogue and appears in the construction disciplines in various guises such as sustainable construction, ecologically sustainable development (ESD), green building, sustainable architecture, and resource efficient construction. The motivation for these activities is to reduce resource consumption and waste and protect the function and biodiversity of natural systems. The desired outcomes are societies that consume energy, water, and materials at a replenishable rate that can be maintained indefinitely while insuring that natural systems are protected and healthy human habitats are created. The widespread implementation of the reduce-reuse-recycle philosophy and other pillars of this concept is implicitly and explicitly advertised to make the earth's finite quantity of materials virtually inexhaustible. Issues such as population growth, quality of life, and standard of living are tacitly assumed to be accounted for, and addressed within, the framework of sustainability. The reality is that sustainability is constrained by the laws of nature, including thermodynamics, chemistry, time, and perhaps the underlying chaos present in nature. The high degree of self-organization in nature was powered by the availability of solar energy, allowing the complexity found in natural systems to develop. Similarly, the complexity of manmade systems is permitted by the consumption of large quantities of high quality energy that ultimately finds its way, via inefficiency and natural limitations, to low temperature, largely useless thermal sinks. Sustainable development is a highly complex issue with a significant moral component: the current generation must pass on its inheritance of natural wealth, not unchanged, but undiminished in potential to support future generations [1]. Many of the problems encountered as the movement to sustainable behavior is explored have technical solutions but technical solutions are not always possible [2]. People and institutions often have to intervene where pure market forces are unable to correct the behavior of economies that tend to deplete and destroy natural systems.

2 Framing the Debate

There are several sides to the argument about whether humans can continue to increase both their population and aggregate consumption at present rates. At one extreme, the *anthropocentric view,* are those who believe human ingenuity can always develop materials, processes, or systems to compensate for depleted natural resources and damaged ecosystems. The other extreme, the *gaia view,* holds that the earth is itself a living system, that by destroying this system by land development, extractive industries, polluting transport and industry, throwaway attitudes, and a general disregard for nature, mankind is compromising its very existence [3]. It is likely that both of these polar opposites exist simultaneously, not unlike the dual wave-particle behavior of photons. Nature is being ravaged by mankind, the survival of many species is in question, rainforests and fisheries worldwide are being destroyed at an accelerating rate, and the atmospheric concentrations of greenhouse gases continue to rise at an increasing pace. At the same time mankind has proven to be clever and adaptable, with an incredible array of technologies being developed at an ever increasing rate, materials use per capita actually dropping in industrialized countries, and a significant swing in attitude and consciousness toward environmental friendly behavior occurring worldwide. Knowledge can increase the efficiency of natural resource use [4]. However, in spite of mankind's knowledge, four major classes of human activity are rapidly destroying the environment and ultimately mankind's life support system: (1) the alteration of planetary ecosystems, (2) the depletion of nonrenewable resources, (3) the unsustainable use of renewable resources, and (4) the pollution of earth, land, and water systems.

3 Alteration of Planetary Systems

The earth's total surface area of 510 million km^2 consists of a terrestrial component of 147 million km^2 and an aquatic component of 363 million km^2. The Net Photosynthetic Production (NPP) of the terrestrial area is 132.1 billion metric tons (MT) and is estimated to be 92.4 billion MT for the aquatic component. Humans are coopting almost 40% of terrestrial NPP and almost 30% of aquatic NPP [5]. It is likely that the coopting of NPP is proportional to population and a doubling of world population from 1986 to 2026 (5 billion to 10 billion) will result in 80% of terrestrial and 60% of aquatic NPP being coopted. Although the exact consequences of this doubling is unknown, it is probable that the effects will be devastating for global ecosystems. It is unknown at what level of stress these natural life support systems simply collapse to a level where human life itself is threatened. For example, in 1997 fisheries in most oceans around the world are in crisis as numerous species are being severely depleted in an unsustainable fashion that is likely to lead to their extinction. The bottom line is that the co-option, destruction, and diversion of terrestrial and aquatic resources by humankind is contributing to rapid and widespread extinction of species and genetically distinct populations, and the genetic impoverishment of the survivors.

Humans are also appropriating a vast percentage of the natural flow of water for their own uses. Total global runoff of freshwater is 40,700 km^3 annually, with only 12,500 km^3 actually accessible for human use. Currently mankind uses approximately 2,285

km^3 or 18% of the total accessible runoff (AR). Projections forecast human appropriation of approximately 9,830 km^3 or over 70% of AR annually by 2025, assuming per capita water consumption remains constant in the future. The effects of this enormous increase in water appropriation will inevitably cause the further decline of fish populations and extinction of many species [6]. Although world energy consumption and accompanying global warming are serious concerns, it could be the need for water that limits local and global economic development. The increasing pollution of world water bodies, particularly in light of the rapid growth of Asian economies, is another enormous problem. China in particular is at risk with damage to natural ecosystems so severe that the recovery of these systems, even with extreme shifts in policy and activity, is very unlikely. Humans are appropriating a massive proportion of ecosystem goods and services and dumping staggering quantities of waste to air, water, and land. Yet humans are just one of an estimated 5 to 30 million organisms [7].

The signs of planetary stress are clear. Earth's average temperature in 1995 was 15.39°C, the highest recorded average annual temperature. The ten warmest years in the last 130 years have occurred in the 1980's and 1990's. Insurance industry payouts in the U.S. for weather-related damage have climbed from US$16 billion in the 1980's to US$48 billion thus far in the 1990's [8]. Acid rain is threatening both freshwater fish and forests due to the emissions of sulfur and nitrous oxides from the combustion of fossil fuels in power plants and automobiles. Species extinction rates are 100-l ,000 times higher than before the arrival of mankind with a potential acceleration to 1,000-10,000 times higher if now-threatened species become extinct in the next century [8]. Far fewer species exist and the complex web of life created through billions of years of evolution is being unraveled in just a few hundred years. Logging, mining, agriculture, and grazing are degrading watersheds. Over 85% of U.S. inland waters are artificially controlled. Over half of U.S. wetlands, excluding Alaska, have been drained but only recently has their essential roles in stormwater control, biodiversity maintenance, and clean water become evident. The alteration of planetary systems has potentially dire consequences for humankind because of the wide range of services that natural systems provide that benefit humans and human settlements (Table 1). The value of these services is estimated to be US$33 trillion annually, with a range from $US 16 trillion to $US54 trillion per year. World economic output is approximately $US18 trillion per year, giving a ecosystem-to-GNP ratio of about 1.8. Although placing a monetary value on natural systems is abhorrent to some, it is also true that decisions are often made on the financial consequences of an activity, whether in the public or private sector [9].

Air quality enhancement/maintenance
Soils for food, wood, and paper production
Ambient temperature enhancement/maintenance (hot weather moderation)
Dampening flood peaks
Filtering and recharging groundwater
Reduced urban-chimney effects
Erosion control (cover, slope component, rainfall, wind, and soil texture components)
Renewable energy sources (solar, wind, biomass, geothermal, tidal)
Tree, bush, and flower pollination
Albedo change forces (energy budget for plants and animals)
Providing evapotranspiration cooling and shade for animals, people, and buildings
Food and water for wildlife
Dampening vertebrate pest damage to crops and other land production
Recreational and tourism areas and area access
Grazing for domesticated animals
Providing noise barriers and separation
Natural fires (for secondary succession conditions)
Carbon, energy, and water storage
Hazard reductions of several types

Table 1 Goods and services provided by natural systems

4 Resource Depletion

At present all signs point to rapid depletion of both renewable and non-renewable resources. While economies are using materials and energy more efficiently than in the past, the sheer number of people is causing total materials and energy consumption to rapidly increase. Forests are being depleted at an accelerating rate, from 40% of the earth's land surface 1,000 years ago, to 30% in 1900, and only 20% at present [8][10]. In addition to the loss of 1 acre per second of rainforest, temperate forests are being destroyed at an equally astonishing rate. Each year 4 million hectares of forests in Siberia and 1 million hectares in Canada are being lost. World grain production per capita has already peaked, with 465 million tons in 1987 adequate for 104 days use, shrinking to just 229 million tons, adequate for 48 days use in 1996 [9]. World fishery productivity has also peaked, growing from 22 million tons in 1950 to 100 million tons in 1987 with only 90 million tons in 1995. Large numbers of ocean species are under threat of extinction including sharks, orange roughy, blue fin tuna, beluga sturgeon and grouper. Worldwide, soil erosion is occurring at 25 billion tons/year, a rate far exceeding the ability of natural regeneration, making it essentially a nonrenewable resource [11].

5 Issues of Waste and Pollution

Humans are the sole species whose waste is not the food or a resource for another species and the waste generated by human activities is enormous. U.S. municipal solid waste ranges from 125-200 million tons depending on the source of the information. Construction and demolition (C&D) waste per capita in most OECD countries is about 0.5 tons or approximately 125-130 million tons annually in the U.S. compared to the official estimates of U.S. C& D waste of 25 million tons per year. Industrial waste in the U.S. amounts to 12 billion tons on a wet basis. Virtually all this waste is sent to engineered landfills with an insignificant recycling or reuse. Materials extracted from the earth's crust and then concentrated for industrial purposes do not simply disappear as a consequence of human activity because the earth's matter is essentially constant. It is the dissipation of high quality, concentrated materials that causes many of the world's environmental problems, including heavy metals that tend to buildup in river bottom sediments. This dissipation effect corresponds to entropy in thermodynamics, a conversion from useful to useless [12] [13].

6 Strategies for Sustainability

Some economists from a new school of thinking known as ***ecological economics*** suggest that the world economy must attain a ***steady-state*** condition where the matter-energy throughput reaches a sustainable level, with a good quality of life and constant income level for individuals, and a stable world population. This clearly conflicts with the underlying assumption of sustainable growth of the economy. Another vision suggests that the economy can continue to grow if low resource consuming sectors such as services, information, culture, education, and finance are the basis for growth rather than material-energy intensive industries [8]. To provide the bare essentials for the world's current population would require a factor of ten increase in economic activity. Technology will have to improve by a factor of twenty to maintain current levels of environmental burden [14]. The Rocky Mountain Institute and the Wuppertal Institute provide evidence that a factor of four increase in resource efficiency is achievable with existing technologies, giving at least a modicum of hope that the world can move far closer to sustainability [15].

One line of thinking on how business and industry can shift onto a path of sustainability is for companies to accomplish this change in three stages. Stage One would be a shift to pollution prevention from pollution control, driven in part by new international standards such as IS0 14000. Stage Two would be product stewardship, with emphasis on minimizing the life cycle environmental impacts of products using concepts such as Design for the Environment (DFE). Stage Three involves the development of clean technologies, changing the technology base from one that depends on unsustainable behavior to a base that is inherently in sync with natural systems. The very rapid growth of the world's economy, particularly in Asia, is creating substantial environmental problems but also an enormous opportunity to leap ahead technologically to clean processes [16]. The backdrop to this shift in OECD countries is the condition of economies in poorer nations. The economies of these nations cause deforestation, soil erosion, desertification, and species extinction because survival has priority over the protection of valuable ecosystems. The need to survive and the absence of economic growth are resulting in massive environmental impacts in countries whose populations are 75% of the world's people [15].

7 Increasing Resource Efficiency and Reducing Waste

One of the key questions that must be answered in the short term is the role of technology in increasing resource efficiency. It is thought that near-future technologies can dramatically increase resource availability and efficiency [15] [17]. The commonly mentioned increase in resource efficiency to achieve worldwide sustainability is a factor of 4 to 10, depending on the source of the information and the resource involved.

7.1 Materials

Humans are now responsible for more materials movement than geological and weather forces combined. While there has been obvious concern over small quantities of very toxic substances introduced into the biosphere by human activities, what has remained unnoticed is the ***ecological*** *rucksack* of materials as described by Friedrich Schmidt-Bleek of the Wuppertal Institute. Megatonne quanitites of material movement must be examined in addition to the microgram quantities of especially harmful substances. Materials Intensity Per Service (MIPS) is one measure of the efficiency of materials use with MIPS for gold being 1:350,000, that is, 350 kilograms of materials processing produces one gram of gold. MIPS for cement is 1: 10, far lower than gold but huge quantities of cement are produced annually worldwide. Schmidt-Bleek estimates that a factor of ten improvement in MIPS in OECD countries must be achieved to reduce the consequences of the ecological rucksack and create a sustainable flow of materials [15]. This is achievable only through extensive reuse and recycling of materials and other measures that minimize the dissipation of previously concentrated materials.

Significant progress has been and continues to be made in the dematerialization of industrial economies. Today automobiles are far lighter, fiberoptics transmit vast quantities of information at a fraction of the weight of copper wiring, computers are smaller and lighter, and the use of aluminum and plastics has significantly reduced the mass of packaging and many common products [17]. However these reductions in MIPS are more than offset by increasing consumption and population and total materials consumption continues to rise.

7.2 Energy

Overall energy efficiency of industrial economies is about 5%, due largely to the number of stages of production (resource extraction to delivery of end service) and the relative inefficiency of each stage. Ultimately, overall efficiencies could approach 50% if the number of stages is reduced and stage efficiencies are greatly increased, both of which are feasible to accomplish [17]. Significant progress has been made in reducing energy use. Although energy use in the U.S. remained relatively flat between 1973 and 1986, economic production expanded by 40%. Similar developments occurred in Japan, the United Kingdom, France, and Germany [4].

8 Applying Sustainability to Construction

If sustainability principles are to apply to industry, government, and the economy, it is clear they must also apply to construction, an industry whose end products consume a significant proportion of all materials and energy in their creation, operation, and deconstruction. In the U.S., the construction and operation of the built environment consumes in excess of 30% of all energy and 40% of the materials produced by the economy. Compared to other commercial activity, construction may be the one least able to respond to a shift toward sustainability, due largely to the nature of its creation. Unlike automobiles, most buildings are for the most part unique and are assembled from a combination of manufactured goods (windows, doors, air handlers, transformers), products tailored for the processing on-site (lumber, gypsum board, roofing, electrical wiring, conduit, ductwork), special liquids with low mass (paint, glues, mastics, sealants), and items that are comprised largely of raw materials moved in bulk to the construction site (fill materials, aggregate, concrete). Each building is assembled on-site with little thought to its final disposal. Much effort has been invested in reducing the operating costs of buildings and technology has been developed to reduce energy and water consumption. However little or no investment has been directed toward creating a systematic and standardized DFE strategy for buildings. Environmentally sustainable design and green building efforts have focused on energy and water consumption, indoor environmental quality, and some methods of reducing building impacts on the local environment during construction and operation. But again, there has been virtually no effort devoted to designing all components and the entire structure for ultimate disassembly for component reuse or recycling. For sustainable construction to evolve, the built environment must be rethought using the ideas emerging from industrial ecology (IE) and DFE. The result, in addition to the significant progress resulting from ESD, sustainable construction, and green building movements, would be structures that are designed with total reuse or recycling of all materials as a front-end goal. For materials, this thinking must be instilled at three levels of design. First, all materials in buildings must be recyclable or the components they comprise must be reusable. Second, all manufactured products must be easily disassembled for recycling, implying a standard labeling system that identifies the materials in each component. Third, the building itself must be designed for easy, future disassembly. Similar to IE, all activities involved in producing the building must provide for the recycling of waste created during the construction process. Shifting to on-site manufacturing plants designed to minimize and recycle waste could help achieve this end.

Building design itself must be transformed for sustainability to be adequately addressed. The fundamental principle to be followed is that the best protection that can be afforded natural systems is to use as little material, energy, water, and land resources as possible. Minimizing resource consumption is the maxim that designers must follow to cause this to occur. The ingredients for success include (1) excellence in planning, (2) design of adaptable, durable structures, (4) extensive application of passive energy design, and (4) incorporation of high efficiency energy consuming systems using renewable resources.

Well thought out planning insures buildings will maintain their purpose for long time frames without the need for their removal. Proximity to multi-modal transportation comprised of mass transit and bicycle routes is one of the crucial steps to reducing reliance on automobiles for transit. Mixed use communities are also a necessity and the Transit-Oriented Development (TOD) and Traditional Neighborhood Development (TND) movements in the U.S. are encouraging bicycle, pedestrian, bus, and light rail transit over automobile use.

Long life, durable, adaptable structures provide by far the best means of minimizing materials consumption. Employing DFE will ensure the materials in these structures can be readily reused and recycled. Passive energy design and high efficiency energy systems can reduce energy consumption to the absolute minimum. Low flow fixtures, greywater and rainwater harvesting systems can minimize water use. Excellent interior environmental quality promotes the health and increases the productivity of the occupants. Finally, high quality design provides the building with an inherent character that society will value, prolonging the desire to preserve their use for the long term. Excellence in planning and design provides the foundation for a sustainable built environment. Adhering to these principles would produce sustainability in construction.

Challenges and Opportunities in UK Housing into the next Century

Paul Evans, BSc., BArch., RIBA
Environmental Best Practice Division, Building Research Establishment, Garston, Watford, UK.

Abstract
Issues concerning the location of new housing and demographic trends serve to highlight the challenge faced by the UK in reducing carbon dioxide emissions to a sustainable level. Statutory and voluntary energy initiatives are referred to as examples of the ways in which the UK Government is tackling the problem.

Current UK Best Practice in the housing field is illustrated by 'a review of ultra-low-energy homes' carried out in 1995, which produced two reports containing examples of low energy and environmentally responsible dwellings. Key aspects of the design of low energy houses using a range of construction systems are highlighted. Built examples are referred to such as the urban autonomous house in Nottinghamshire by Robert and Brenda Vale and The Berm House, Field and Conference study centre in South Wales. New research initiatives into sustainable building practices such as Sherwood Energy Village (a proposed net zero CO_2 autonomous community in Newark and Sherwood), Nottinghamshire will serve to highlight the possible future direction of Best Practice in the UK.

Multi-disciplinary and inter-disciplinary working practices are referred to with reference to the writers participation in a new 'Interdisciplinary Design for the Built Environment' course at Cambridge University in England. The aims of the course are to encourage consultants from a range of backgrounds including Architects, Engineers, Quantity Surveyors and Transport Planners to participate in building design team groups. This part of the paper attempts to define a possible 'way forward' in terms of interdisciplinary or team working methods as a contribution to better working practices and a more sustainable future for the construction industry.
Keywords: UK energy initiatives, Best Practice, Interdisciplinary Design.

1.0 Introduction

This presentation will focus on 3 themes:

- Methodologies and Regulations, highlighting current UK Government regulatory and non-regulatory frameworks for energy conservation and the reduction of emissions of carbon dioxide.
- Open Design and Production Process, citing Best Practice examples of low energy housing in the UK.
- Management and Organisation explaining how interdisciplinary working practices may provide opportunities for producing more sustainable buildings.

2.0 UK energy consumption

The UK is an area of relatively high CO_2 emissions from fossil fuel combustion in relation to population. The UK has 1% of world population and approximately 2.5% of CO_2 emissions. The total energy expenditure in the UK is over f52 billion per annum, of which about 41% is used in buildings, slightly less than the transport sector but significantly more than the industrial sector.

Looking at the buildings sector in more detail, housing is the single largest consumer of energy accounting for some f 14 billion per year (65%) – the same order of magnitude as defence expenditure or education.

3.0 Transport and planning

One of the key issues with regard to sustainability is that of transport planning and land use. The Royal Commission on Environmental Pollution (1994) stated that: The unrelenting growth of transport has become possibly the greatest environmental threat facing the UK and one of the greatest obstacles to achieving sustainable development.

The Government has published a guide to Planning Policy Guidance Note 13 [1], which looks to reduce dependency on private motorised forms of transportation. This document emphasises greater integration of land use and transport planning by:

- Minimising travel distances
- Encouraging modes other than the car
- Improving accessibility to facilities

Ideas regarding the form of new settlement patterns, which may help to reduce transport dependency and reduce pollution, are emerging. These include pedestrian pockets, urban villages and compact urban forms. Taking the urban village as one example, this comprises good transport links with a rail network passing between the villages. There are local shops at the cores and all housing is within 5 minutes walk of local amenities. This starts to address the problems of transport dependency - putting more into good public transport, encouraging people to walk and cycle. It is important to remember that it is pointless getting the detail of house design and construction right if the savings being made in house running costs are offset by increasing energy expenditure in transport.

Most of our towns and villages in the UK are already built so we will also need to think about regeneration in urban areas. Research suggests that urban compaction or the compact city may offer the best solutions to reducing private travel. Densities below 29 persons per hectare tend to increase transport energy use [2].

High density urban living in attractive urban locations with perhaps revised planning rules for reducing car parking densities would provide safer and more attractive places to live. Maisonette type accommodation with urban greenery and limited parking provision outside the dwellings is one type of development which may be appropriate in inner city areas.

Demographically, by the year 2016 an estimated 4.4 million new households [3] will be needed in the UK of which about 3.5M will need to accommodate single people. The Joseph Rowntree publication entitled '21st Century Homes Building to Last' [4]. discusses these trends in greater detail and in particular questions whether we should be building for more diverse and sophisticated needs of homeowners. House types should be flexible enough for people to adapt as their needs change in the future.

4.0 Housing energy initiatives

In the UK, there are a number of key Government statutory and non-statutory energy initiatives and I would like to talk about 2 of them:

- The SAP [5] introduced into the UK Building Regulations in 1995 and therefore mandatory for new housing.
- The Environmental Standard - The Building Research Establishment's Environmental Assessment Method (BREEAM), for new housing [6] - a voluntary standard.

4.1 The Standard Assessment Procedure (SAP)

The SAP is the Governments preferred method of Home Energy Rating and is based on BREDEM 12, the Building Research Establishment's Domestic Energy Model. It is a simple 1- 100 scale, the nearer to 100 the more energy efficient the house.

SAP can be used as a method of compliance in the Building Regulations. To demonstrate compliance the SAP rating needs to be between 80 and 85 depending on the area of the dwelling. For example a dwelling of 80 sq. metres will need a SAP rating of 80 to comply, while a dwelling of 120 sq. metres would need a SAP rating of 85 to comply using the Energy Rating Method.

However, there are alternative methods of compliance and there is no obligation to achieve a particular SAP rating. Higher U-values are justified for the roof, floor and windows of dwellings having SAP ratings of 60 or less.

SAP has necessitated those working in the housing energy field to consider a more holistic, integrated approach to house design. Consideration needs to be given to heating, fabric and ventilation issues together.

4.2 The Building Research Establishment's Environmental Assessment Method.

BREEAM is intended to translate the rather general principles of sustainable development into specific requirements which can direct and influence action.

BREEAM sets out technical performance criteria for buildings, components, systems and materials. BREEAM is a voluntary, self-financing scheme for the environmental labelling of buildings developed by the Building Research Establishment with private sector partners and sponsors. Individual buildings are awarded Certificates based on the performance of the building against a set of defined environmental criteria.

This certificate can be displayed in the building, or used in the promotional portfolio, and may form part of the developer and occupier's overall environmental policy statement and management system. BREEAM is now international, with schemes being launched in Canada (1996) and Norway (1995) based on BREEAM. Countries such as New Zealand, Australia, Sweden and South Africa are discussing developing versions of BREEAM for their particular climate, social and market conditions, and national priorities.

BREEAM for new housing was renamed The Environmental Standard Award in 1995. This seeks to minimise the adverse effects of new homes on the global and local environment while promoting a healthy indoor environment.

The environmental assessment, which is carried out at the design stage, is based on readily available and generally accepted information. The method, which provides a pass/fail assessment, identifies and credits designs where specific targets are met. Designs are not expected to gain credits for every issue assessed. Assessors licensed by BRE carry out assessments. Where large numbers of buildings are to be assessed, developers may apply for a licence to assess their own buildings.

5.0 Review of ultra-low-energy homes in the UK

In 1995 the Building Research Establishment instigated a review of ultra-low-energy homes [7 and 8] to identify examples of low energy sustainable homes. The aim of the review was to identify 40 ultra-low-energy homes in the UK and 12 from overseas.

The criteria adopted for the selection of UK schemes included:
* Fabric U-values of 0.2 or less
* Glazing U-values of 2.0 or less
* A well sealed construction
* Total delivered energy of less than 100kWh/m^2 per year
* Innovative or unusual construction techniques or heating systems and schemes of particular architectural merit

Obviously only the very best schemes can satisfy all these criteria. Many of those included fall short in some areas but are included because they are good examples of particular construction techniques or one of the other criteria. A large number of the projects identified are in South East England, particularly the Milton Keynes areas.

The research examined various external wall construction types and examples are categorised into:
* Masonry
* Timber frame
* Steel Frame
* Concrete
* and earth-sheltered construction.

5.1 Masonry

The Autonomous Urban House, Southwell, Notts 1993. Designed by Robert and Brenda Vale. Almost totally self-sufficient in its energy use. Features include stored and filtered rainwater, collected from the roof via copper rainwater goods. There is also a cornposting toilet and a soakaway for grey water. The total measured energy consumption for the house is about 22kWh per m^2 year and this is impressive when you consider that there are only a handful of schemes in the UK that are under 100 kWh/m^2.

The external walls from inside the conservatory, is double-glazed. The windows in the external walls are triple glazed. There is through the wall mechanical ventilation and heat recovery units in 'wet' rooms taking preheated air from the conservatory. In most aspects, it appears that the standard of living achieved in this house is on a par with typical UK households. The local planning authority has become extremely enthusiastic about the house. It has a stated policy of achieving another 100 houses of this type by the year 2000.

The external wall construction comprises an inner leaf of 100mm dense concrete block with 25Omm built-in mineral fibre bats and plastic ties. A brick facing was used on the outside and this achieves a U-value of 0.14. The builder's total price for constructing the house including the purchase and installation of the PV system was about f 155,000.

Creswell Road, Darnall in Sheffield. The client for this project was North Sheffield Housing Association. The project consists of 2 semi-detached houses. Each house is $88m^2$ but built with no additional cost when compared with equivalent standard houses. Infact, there was a minus overcost and the surplus funds were used to make the houses larger than normal. The lowest tender received to build the scheme was £3,000 per housing unit below the Housing Corporations normal budget per unit.

The external wall construction briefly comprises aerated concrete block, 150mm built in mineral fibre bats with clay brick outer skin. The external wall achieves a U-value of 0.2 1. The roof consists of 400mm of cellulose fibre and there is a further 150mm of insulation in the floor. Note that instead of using a cavity closer the insulation is continuous which avoids problems of thermal bridging. Independent lintels also minimise thermal bridging.

Dr Susan Roaf's residence in Oxford. The north front of the house is unremarkable in many respects. The clue that this is no ordinary house is parked outside the front of the house - an electric car powered by a PV array which has a range of about 50 miles and ferries the owner to and from work.

On the south side of the house there is a PV array that powers the electric car and passive solar design to maximise solar gain. The house also utilises flat plate solar collectors for water heating. The total costs of the house incorporating this range of technologies are around £$800m^2$. There is a question mark regarding cost effectiveness and payback with such technologies in the UK at present but perhaps you might expect a house utilising a range of new technologies to be more expensive initially.

The more widespread adoption of such technologies will help to reduce costs and encourage their wider adoption.

The specification for the house briefly comprises:

Occupied area - 233m2
Roof U-value = 0.14
Walls U-value = 0.22
Ventilation = 0.5 ACH
Ground U-value = 0.19
Windows U-value = 1.3
Solar hot water - 4kW peak

5.2 Timber frame

The timber frame example is from the Futureworld exhibition in Milton Keynes being a 2 bed detached house built by Admiral Homes. The extraordinary think about this scheme is that it is the only all electric house that has achieved a BREEAM 'excellent' rating – the highest possible.

The external wall construction consists of double stud construction with a total wall thickness of 460mm. From the inside we have 12mrn plasterboard with a 50mm service cavity behind and a polyethylene vapour barrier. Then a total of 235mm of mineral fibre compressed within the stud construction, plywood sheathing, breather membrane and a 50mm clear cavity. On the outside 102.5mm brickwork. This wall construction achieves a U-value of 0.15. The construction cost was about 20% more than Admiral Homes usual speculatively built timber frame houses.

5.3 Earth sheltered examples

An earth-sheltered example is the *Caer Llan Field Study and Conference Centre, Monmouth 1987.* The project was conceived in 1980, the aim being to reach zero space heating energy. This was achieved with a normal annual range of temperatures for the guest rooms varying from 17.5 to 24.5°C. Although there is no space heating, ventilation has to be provided mechanically. Ducts run the length of the building in the solar corridor and supply air to the rooms recovers a certain amount of heat from the exhaust air. The insulation slabs throughout the building are sealed at seams with in-situ polyurethane foam.

The second earth sheltered example is *Hockerton Houses, Southwell, Notts. 1995* designed by Robert and Brenda Vale. This comprises five terraced houses each $122m^2$. The local planning authority gave the scheme planning permission in the open countryside on the grounds that its environmental benefits outweighed the disadvantages. It features triple glazing, solar water heating and no space heating. The external wall on the south side is a timber framed conservatory, which will obviously allow passive solar gain.

5.4 Sherwood Energy Village

Sherwood Energy Village is intended to be an exemplar model for a sustainable community. The energy emphasis of the village builds on its past as a provider of energy based on coal and looks forward to a future based on renewable energy. The village will be serviced from local resources and could lead to a considerable degree of autonomy.

To achieve this, the layout of the village will aim to minimise the need for transport and allow the growing of food. The basis of the village will be the concept of increased autonomy. Some of the houses at Sherwood Energy Village will be independent of mains sewerage and water.

The detail is still being developed but the intention is that the site generates energy, provides its own water and deals with its own waste. The layout will benefit from south facing solar gain and it is intended that there will be some use of photovoltaics for electricity generation. The houses are quite ordinary in many respects. An integrated package of energy efficiency measures includes super insulation and very low space heating demand. The scheme will consist of 62 units built at reasonable cost.

5.5 Summary

Summarised, the main points of the review of ultra-low-energy homes are:

- The majority of schemes are in SE England and obviously a large number in Milton Keynes which is renowned for its low energy housing.
- Only about 4 schemes achieved under $100kWh/m^2$ energy consumption. This was partly due to inadequate heating system specifications and high air leakage rates.
- Some examples had innovative detailing and novel construction.
- Some of the houses are utilising mechanical ventilation systems to achieve the air change rates required and passive stack systems are also in use.
- Costs vary enormously. The range of costs in the houses reviewed was from about f $250m^2$ up to over f $800m^2$.

Interdisciplinary design for the Built Environment

The writer has recently completed an Interdisciplinary Design for the Built Environment Course at Cambridge University in England. The course is a response to an increasingly . widespread belief that the complexity of the problems facing the designers of the built environment cannot be met solely from the confines of existing professional roles.

Bringing together groups of professionals in multidisciplinary teams encourages teamwork and collaborative design. The Course encourages designers of the built environment to improve the efficiency of the industry and at the same time care for and enhance the wider environment (natural and man-made) in which they work. This is achieved by setting up Interdisciplinary teams at the early design stage of projects enabling input from a range of backgrounds. This enables the form and layout of proposals to benefit from the experience of a range of expertise. Examples include the early input of the Client to determine the optimum location and phasing of development on a major site in Cambridge. As an Architect, my primary concern was to achieve quality of space in the masterplan. My experience did not extend to which parts of the site might prove most lettable. However, I was familiar with ideas of compactness, urban villages and the importance of variety in urban space. This set up a dialogue between two people of differing backgrounds and inevitably requires compromise in the type of final solution agreed upon.

A second example is the important interface between Architect and Services Engineer. Traditionally, the Service Engineer may not be brought in to a project at an early stage. This may lead to the Services aspect of the building being applied to the design at a late stage. The Interdisciplinary approach favours the Services Engineers input being utilised early in the project. This allows consideration of the services aspect of the design to be truly integral.

I anticipate that the Interdisciplinary approach will prove successful in the UK. The Course is still in its infancy but has already attracted people from a wide range of disciplines and backgrounds. Regular Conferences provide a forum for feedback and debate for students on completion of the Course. The Course itself comprises lectures from leading Practioners in the field delivered at residential periods at Cambridge over two years part-time. I commend this approach to other Consultants in the field.

7.0 Conclusions

This paper has highlighted the challenges facing the UK in achieving more sustainable housing. UK Government energy initiatives including the Standard Assessment Procedure and The Environmental Standard are raising awareness among those involved in house construction.

A review of ultra-low-energy built examples suggests that there are now a significant number of such homes in the UK utilising a variety of construction systems and environmentally beneficial features such as low embodied energy and water saving techniques. The study highlighted the fact that there are still relatively few houses using less than 100kWh/m^2 energy consumption. This is due mainly due poorly commissioned heating systems and high air leakage rates.

The writers participation in an Interdisciplinary Design for the Built Environment Course at Cambridge University has pointed to a future based on a better understanding of the role of other disciplines in the built environment. Creating sustainable environments and buildings will require input from a range of expertise each sharing common goals. These might include targets for building energy consumption, proximity to public transport and so on. Solutions will undoubtedly lie in contributions made by multi-disciplinary teams, members of which will have been involved early in the design process.

A Simulation of the Urban Environment in Salford

A. Hamilton and S. Curwell
Research Centre for the Built & Human Environment, University of Salford, Salford, UK
T. Davies
MSc student, Department of Surveying, University of Salford, Salford, UK

Abstract
This paper argues the case for a new type of computer based simulation of an urban environment and gives an account of a project to build such a simulation. The Chapel Street redevelopment area in Salford, in the North West of England, is to be used as the prototype. The simulation will model economic, environmental and social factors of life in this area, using a holistic approach, so that the regeneration can be analysed and projections into the future can be made, which will inform planning and policy making.

We review current city models which we categorise as “analytical” and “graphical”. The strengths and weaknesses of these models are noted. A design for a new type of city simulation is put forward that builds on the strengths of current models and avoids their weaknesses. The approaches and technologies needed to build the new city simulation are considered and a plan for implementation is put forward.

The simulation will be implemented using Case Based Reasoning (CBR) Expert System software that will “learn” from use, reducing development time and facilitating continuous development. This feature will enhance the modelling of changing social parameters to provide a dynamic view of human activity. To enhance usability it will have a graphical interface.

The simulation will draw on our current work. Presently we are working on a cross cultural comparison of local Agenda 21 strategies, in Chapel Street in Salford and Spina 3 in Turin in partnership with Turin Polytechnic. We are also co-ordinating the pan European BEQUEST network concerned with the evaluation of the quality of urban life. These projects, involving a number of European partners, are informing our conceptual model of a city. We will also make use of innovations in Case Based Reasoning, including the linking of CBR to Virtual Reality on the Internet, that are the result of IT research at Salford. This work will be the basis of the modelling engine to be constructed, and the interface to the engine. We are taking a soft systems approach to building up the conceptual model that will be the basis of the modelling engine.

We aim to meet the needs of planners, policy makers, and citizens, by taking a holistic approach to model design, using appropriate new technologies, and also incorporating the best features of existing analytical and graphical models.

Keywords: city, environment, model, simulation, sustainability, urban, virtual reality

1 Introduction

Cities are dynamic living organisms that are constantly evolving. Thus city planning has always been difficult. Today our rapidly changing society makes the job of predicting future needs of city dwellers, and those who depend on the services cities provide, even more problematic. Particular problems include: transport, pollution, crime, conservation and economic regeneration. Furthermore, in planning for the future, it is essential to take a holistic view of the sustainability of cities, as identified in Agenda 21, [1]. Thus in addressing the complex problems of city planning it is not sufficient just to be concerned with the physical structure of the city; the interplay of intangible economic, social and environmental factors needs to be considered as well, [2].

Those involved in the sophisticated art of city planning use a variety of tools. These already include city models. It is useful to review what is currently on offer in city modelling in order to inform the design process of new models.

2 A review of current city models

We have categorised current city models as "Analytical" and "Graphical". Analytical models process quantifiable data to give indicators of city life, for-example, expected pollution levels associated with particular fuel use and traffic flows. Graphical models show what an existing cityscape looks like, and can generally incorporate- renditions of proposed developments to display possible future cityscapes. Examples of these models are discussed below.

2.1 Analytical models: Leeds and Cardiff

The Leeds Quantifiable City is a typical analytical model. Work is still in progress on this model produced by the Environment Centre of Leeds University with over £1 million of research grants over the last 10 years. The aim of the project is to develop a computer model of urban processes that can be used to promote urban development along a sustainable path. The framework for the model is made up of sub systems of the Human Economy, City Metabolism, Ecological Integrity and vitality, and the quality of human life. On this framework a picture of resource use, residuals arising (waste and pollution), and transport is built up. The system monitors people, flora and fauna, renewable and non-renewable resources, and climate. The output variables are sustainability indicators "which are expressed in fine detail", [3].

Leeds University have continued to keep the strong support of the city authorities and it is clear that this comprehensive city model is of value in urban planning. However in a frank discussion with the authors, Professor David Kay of Leeds University, who is a key researcher in this project, pointed out some of the problems with this type of model. These are discussed later in this paper.

The Cardiff model, formally called the Energy and Environmental Prediction model or EEP, is the work of the Welsh school of Architecture. This model is primarily designed to model energy use, the production and dispersal of pollutants, and the health effects of the pollutants. It is to be installed in Cardiff and is being assessed for use in Newport. Camden Borough and Leicester City council have recently become involved with the development of this model, [4]. Both-the Leeds and Cardiff models are funded by the UK research council, EPSRC, and work is presently under way to integrate the modules of these models.

2.2 Graphical models: Edinburgh and Bath

The Edinburgh model was commissioned by the city's Old Town Renewal trust in 1993 and built by ABACUS at Strathclyde university. Being one of the earliest virtual cityscapes, this is now well developed and also well integrated in the planning process. To obtain planning permission in the old town it is now mandatory to supply a CAD model of the proposed development in the appropriate format for it to be dropped into the virtual cityscape.

The Bath Model was produced by the Centre for Advanced Studies in Architecture (CASA) at Bath university using Virtual Reality techniques. Architects and developers now buy sections of the model in which they can place their own proposals and display them to planners and the public. The Bath model was one of the first to be available over the Internet without specialist equipment. Inevitably the quality of the display suffers, due to delays in transmission, but the model makes the point that public perception of a proposed development can be greatly enhanced by the use of this technology, [5].

2.3 An assessment of Analytical and Graphical models

The above review only examines models produced in the UK. However the Leeds and Cardiff models are similar to analytical models produced elsewhere, [6]. Whilst local authorities are clearly benefiting from the analysis of the various aspects of the city incorporated in these models, it is also evident that the models have some weaknesses. Generally they suffer from being "static" in that they are both difficult to update and cannot easily be used to predict changes over a number of years, an essential criteria for strategic policy making. They rely upon those aspects that can be quantitatively measured and do not consider many other aspects that contribute to a good quality of life. Also as they were often designed at a time when there was little regard for the quality of software interfaces, they suffer in terms of usability. Thus their use is restricted to research groups and other highly trained personnel. Interpretation of output is also a problem: it is often unclear what the output of individual parameters indicates in holistic terms. To quote from the Leeds city model team "The problem of assessing the general direction of city development (sustainable or otherwise) using many indicators is acknowledged". This factor also accounts for another criticism of such models: that they are of limited use in forecasting. It is not possible to run the city on for 10 or more years to see how it would develop if a particular plan was put into action. Another problem with analytic models is their quantifiable nature. Although some models do make an attempt to incorporate qualitative factors these are of secondary concern, and do not enable a holistic view of the city.

In contrast to Analytical models, graphical models are generally easily accessible. However the feedback from graphical models is mostly limited to criticism of the visual impact of development proposals. Whilst this feedback could greatly enhance public participation in the planning process, it only addresses one aspect of that process.

Graphical models are developing rapidly and new features are being added, such as those in the Philadelphia model now under development, [7]. However when the Philadelphia model is completed it will effectively be a graphical model linked to an information system, no forecasting will be possible.

3 Towards a new type of city model

It would be useful to have a model that combined the positive attributes of analytical and graphical models but was also able to model qualitative factors and forecast holistic change in a city, rather than changes in isolated parameters, over a period of years. Some of the features of such a model are incorporated in the computer game Sim City.

Sim City was developed by Maxis ltd. a software company specialising in games. The Sim City player is presented on screen with a clear terrain on which to build the infrastructure and plan of a city, with the aid of a graphical toolkit. Services such as roads, railways, power, and water, need to be installed as well as public buildings (police stations, schools, etc.) and amenities. The player cannot build other buildings; instead areas can be zoned as commercial, industrial, and residential. Within the simulation, "Sims", the people who inhabit Sim City, will decide on the type of building, varying from high rise to low rise and humble to prestigious . If an area becomes particularly unpleasant e.g. high volumes of traffic, high crime, and high pollution, they will not build at all, or will abandon existing buildings. The parameters of Sim City are well integrated and thus the development of the city depends on the overall plan. Success can be measured in any way the player chooses. It is possible to plan cities that will develop dense urban areas and high rise offices, or garden cities with low pollution and traffic volumes. The user has freedom to experiment and gets feedback from the experiments.

Because Sim City is a game it is easy to overlook its sophisticated attributes. Most city models employ the *ceteris paribus* assumption, that everything remains the same while one parameter is being examined. However this is almost always false in the real life of a city.-Sim City eschew? this static approach for a dynamic one,-in simulating the evolving city as a whole. Compared to other city models Sim City incorporates a large number of economic, environmental, and social parameters. Furthermore these parameters are dynamically integrated. It would seem that modelling the interaction of these variables is an almost impossible task. However this is achieved in Sim City by approximation. Most Sim City parameters have few possible values, which in turn decreases the complexity of interaction, [8]. This introduces an interesting paradox into the model: accuracy of detail is sacrificed to give a "better" picture of the city as a whole.

The accuracy of this holistic picture is open to question. For instance assumptions are written into Sim City which cannot scrutinised by the user of the system. However the accuracy of what is avowedly a game should not detract from the merits of the modelling methods involved. There are problems with current analytical models in delivering a holistic picture. It could be argued that this is because they are concerned with too low a level of abstraction. It is as if they are trying to understand the behaviour of a complex living organism by studying the chemistry of its molecules. Checkland and Polyani both discuss the futility of such a task in their critiques of the limits of rational science, [9,10]. Checkland refers to "emergent properties" of systems as they are viewed at higher levels of abstraction. In his arguments for "systems thinking", he illustrates the problem of pursuing ever greater detail rather than thinking about a system at an appropriate level in an appropriate way.

The great merit of Sim City is the way it models city problems at a higher and more appropriate level of abstraction, enabling the modelling of radical changes to a city. For example a city can be planned with no roads, and only a rail based public transport system. When this is modelled in Sim City the immediate result is complaints by the city inhabitants followed by a decrease in prosperity. However after a few years prosperity begins to rise again and continues rising, presumably as the benefits of diminished pollution etc. influence the model. It can be argued that this is not a realistic outcome. That it is an outcome, and that the approach can be examined and improved in new models, is less contentious.

4 Design criteria for a new city model

What are the consequences of approaching the design of a simulation of a city at a higher level: sacrificing accuracy of detail in order to generate a holistic picture of the city capable of supporting forecasts?-An obvious consequence would be less reliability on outcomes from the model when considering the quantifiable aspects such as pollution levels. Would this make a holistic simulation unacceptable to planners?

In the consultations we have had with those working in city planning concern was expressed that we might present a single mechanistic view of the parameters that affect the city. It could be said that this concern favours holistic simulations. Furthermore it was argued that on many important aspects of city life it was impossible to get accurate data. On some aspects it seems that even approximations are difficult as different interpretations of cause and effect can result in widely varying estimations. This problem is predicted by existing research into Cognitive Mapping, [11].

These discussions open up another aspect of modelling not incorporated in any of the models we have looked at. This is the ability of the user of the model to set it up to reflect their own interpretation of qualitative aspects of city life. From our discussions it was felt that a configurable system would be welcomed as there are many opinions of cause and effect in the workings of cities. A further advantage would be the ability to see the effect of altered legislation so that "what if' simulations could be run in which national and local policies were changed. This aspect of city modelling would make it a tool for policy making and research into social concepts of city life. It also supports the scientific analysis of cities by conjecture and refutation, [12].

4.1 Meeting needs - uses of the city model.

The justification for this new approach to city modelling must be in meeting the needs expressed earlier in this paper. How is it possible to meet these needs with city models?

The most fundamental use is to display plans, and forecasts of their effects, to make the planning process more democratic and comprehensible. This mode of use is similar to the use of the Bath and Edinburgh models described above. However, by incorporating techniques such as colour coding, the model could also display features such as vehicle and pedestrian traffic flows, areas of high crime rate etc. Different development plans could be compared and a forecast run to show effects on traffic, crime rate, etc. in the years after the development was built. Whilst these forecasts may not have a high degree of accuracy, they could be used for comparative studies and to promote discussion about the possible outcomes.

5 Building a new city model

How can the design outlined above be realised? Our approach is to build a prototype simulation of a small area of a city. This is a selected part of the Chapel Street development area in Salford. The reason for building a small prototype is to concentrate on the conceptual model and its software implementation without being distracted by detail.

To realise the design, it is necessary to have:

* Software on which a city modelling engine can be built that will reflect the dynamic evolving nature of a city.
* A conceptual model, of what a city is, and what happens in it, that will be realised as the city modelling engine.
* Sources of data to inform and build the model.
* Interactivity with the modelling engine that promotes ease of interpretation of the simulation as a whole and enables configurability.

5.1 Software

Recent developments in Knowledge Based systems show potential in the construction of complex dynamic models such as cities. In particular Case Based Reasoning (CBR) can support City Modelling with the following features, [13,141:

* CBR can draw upon surveys and prior cases in order to construct the simulator,
* it will enable a simulator to be built for a domain where we accept that we do not yet fully understand the underlying causes and effects,
* it will enable the city model to acquire new knowledge and thereby handle an increasingly wide range of situations without complex programme maintenance.

In effect CBR systems are able to acquire new knowledge (i.e. learn) as new cases are acquired with time, [15]. Thus as research is carried out into the behaviour of the city, this could be fed into the model to give it greater veracity. A more important aspect of CBR's ability to learn is the potential to model the incremental changes in the environmental, economic, and social aspects of the city. This will enable the representation of the changing expectations of citizens. For example, in areas with wide climatic variations enclosed areas for shopping are becoming the expected norm. A predictive model must reflect trends in behaviour of those who live in the city. This is difficult with algorithmic or heuristic models which require constant expensive maintenance if they are to remain effective.

CBR can provide the two "new" features of our design: support for holistic models and configurability. CBR makes the best fit for the cases it receives, Thus, as long as new data is accurately related to existing data, and the data is otherwise validated, CBR is able to make predictions. Even when data is incomplete CBR will give results ranked in terms of percentage certainty. The properties of CBR also allow for the emergence of unforeseen changes which may be of value in understanding potential future traits in city life, For a user to configure the simulation they effectively make up their own "cases" and put these into the system.

5.2 A conceptual model

A key part of the modelling engine design will be to determine what a city is, and more importantly what it does. To identify the variety of interest groups that can inform us on the nature of the city we have used the work of ATEQUE, [16]. Furthermore, in carrying out this part of the research, we will be using the network of representatives of the ATEQUE groups that we are building up in the BEQUEST project. BEQUEST is a pan European network set up to evaluate the quality of urban environments, [17]. To analyse the information we receive from these sources we will use cognitive mapping techniques. To map out the concept of the city as a whole we will use the soft systems approach developed by Checkland, referred to earlier in this paper. This approach is used in order to make sense of complex systems that incorporate quantitative (hard) and qualitative (soft) aspects. The conceptual model will be flexible enough to incorporate dense, diversified and other city forms, [18,19].

5.3 Data

Data acquisition can be a time consuming and expensive aspect of modelling. Choosing to model a redevelopment area alleviates these costs, as much of the data used in the model will be generated by Salford Council and their consultants as work proceeds in Chapel Street. To provide a physical framework to the model we will be using digital maps as supplied by the UK ordinance survey, and the National Geospatial Database.

These primary sources will be supplemented wherever possible by data collected for other projects. This includes existing city models, the Environmental Change Network Database, [20] and when it becomes available, the UK National Land Information Service, [21]. NLIS is now being prototyped in Bristol.

5.4 Interactivity

Virtual Reality tools have already been integrated with CBR, to provide a versatile graphical interface, [22]. Users of our system will be asked to engage with a simulation that embodies the concept of a city as a living organism, rather than a pictorial representation of the physical structure of the city. Thus we will be designing interactivity between user and simulation with respect to the particular type of engagement expected, [23].

6 Conclusion

In our review of city models it appears that whilst work still continues on existing analytical models, most new models tend to be of the graphical type. It could be argued that this tendency is driven by interest in Virtual Reality technology. However, apart from opening up models to a wider public, VR by itself does little "to promote urban development along a sustainable path" (the aim of the Leeds model). We agree with the aims of those building the Leeds and Cardiff models but we see the need to explore other ways of realising these aims. While current analytical models have been, and will continue to be, of value in planning the future of cities, it is our assessment that they are hampered by outdated technology. They are typically a patchwork of software systems built up over many years. Often the software originally used could only support mechanistic modelling, thus precluding a truly holistic approach.

In planning to produce a new type of simulation we build on the experience of those who constructed earlier models, having the advantage of more sophisticated software tools. However it is a challenging task, but one that needs to be tackled as the potential benefits make it worth the effort.

An Assessment and Optimization Model of Environmental Influence about City Construction Planning in China Three Gorges Reservoir Area

Yingjiu Yang
Wuhan University of Hydraulic and Electric Engineering, Wuhan, China
Yi Yang, Nian Yang
Wuhan University, Wuhan, China

Abstract
In China Three Gorges Reservoir Area, it is planned to migrate 1200,000 people and build 128 towns. For long-term development and duration, this paper presents a multiobjective planning model about city planning, taking account of environmental influence, avoiding some disasters such as flood, landslide, water pollution, etc and optimizing some objectives like afforestation , land protection, city planning function , and so on.
Keywords: city planning, environment, multiobjective, optimization.

1 Foreword

In China Three Gorges Reservoir Area, 19 towns and cities are involved in the inundated area. There are 846,200 people living in area under the submerged water level now, 1200,000 people to be migrated, 470,000 acres farmland and 1599 industrial and mining enterprises to be submerged and 128 cities and towns to be built. In order to build so much cities and towns, environmental influence must be taken into account and the optimum scheme satisfying environmental protection must be chosen one by one.

This paper presents a kind of guiding ideology and an assessment and optimization model of environmental influence about town planning in accordance with the above-mentioned situation.

2 Guiding Ideology

2.1 Objective

Migration is the successful and failing crux of the Three Gorges Reservoir. For long-term development and duration, the environmental influences on construction must be considered. The objective is that the construction works that have good environment, safety and reliability, convenience of production and life for the migrants is created.

2.2 Criterion

The character of these towns is at the foot of hills and beside rivers.

(1)Environmental protection

The environmental qualities that we need are (a) the good environmental conditions of people's working, residence and action. (b)the good ambient conditions of building's formation, exist, maintenance, protection. (c)the good environmental conditions of human existence and development.

Criterion 1: All the natural conditions being beneficial to the environmental qualities are necessary to be protected.

(2)Environmental improvement

Criterion 2: All the artificial behavior being favorable to creating, maintaining, improving the environmental qualities needs to be developed. One content in them is that projects are used to improve the environment. It's expense needs to be scheduled into the total expense of towns construction.

3 Assessment Model

3.1 Affecting factors

When town site is selected and schemes are compared, the following factors must be

taken account of.
(1)Geology: geology, earthquake landslide, mud rock flow
(2)Landform: geomorphy
(3)Climate: rainfall, wind, air temperature, atmosphere pollution
(4)Hydrometic: flood, water quality, ground water
(5)Afforestation: foresting, green space, garden
(6)Land: space area, land protection
(7)Traffic: road, water-transportation, railway cableway
(8)Culture and art: history, culture, custom, education P. E. , amusement
@Planning designing construction: planning technique, design technique, construction technique
(1 0)Water supply and sewerage
(11)Energy power: power source without pollution
(12)Food: production and supply of food
(13)Economy: industry, agriculture , tourist industry, etc.
(14)Sanitation: environmental sanitation, hospital, the prevention and cure of schistosomialsis and disaster of insects pest etc.

3.2 Assurance condition

It must be satisfied the assurance conditions, including avoiding and preventing landslide, earthquake, mud rock flow, flood inundation, atmospheric pollution, wind storm, schistosmiasis and so on, otherwise the scheme of the towns planning will be abolished.

3.3 Multiobjective

The objectives of scheme optimization include(1)town afforestation (2)land protection (3)culture and art (4)complete function of city planning (5)traffic modernization (6)developing on economy (7)total expense (8)construction period.

3.4 Objective function

The corresponding objectives functions include:

(1)Afforestation ratio: the ratio between the afforestation area and the land use area
(2)land protection ratio: the ratio between the water-and-soil conservation area in the range of influence on city environment and the range of that;
(3),(4),(5)are represented as excellent, good, medium, bad, worst;
(6)One year GNP (10,000 yuan);
(7)Total expense (10,000 yuan);
(8)Time (month).

The objective values for qualitative factors are determined by the following standards:

The value of excellent fetches a data between 80 and 100.
The value of good fetches a data between 60 and 79.

The value of medium fetches a data between 40 and 59.

The value of bad fetches a data between 20 and 39.

The value of worst fetches a data between 0 and 19.

The larger (1), (2), (3), (4), (5), (6) are, the better, and the smaller (7), (8) are, the better, 8 characteristic values are confirmed as the objective function values for the different schemes.

3.5 Multiobjective Optimization Model

Taking the assurance conditions as the restrained conditions, the multiobjective is optimized. It is more complicated and difficult than single-objective optimization.

$X(x_1 \sim x_n)$ represents the variables of a scheme. There are 8 objective functions: $f_1(x), \ldots, f_8(x)$

Optimizing the functions represent

$$\text{Max}\,[f_1(x), f_2(x), \ldots, f_6(x)] \tag{1}$$

$$\text{Min}\,[f_1(x), f_2(x)] \qquad x \in D \tag{2}$$

Satisfying each restrained condition represents

$$g_u(x) = 0 \qquad (u=1 \sim m) \tag{3}$$

If $f_1(x) \sim f_8(x)$, each single objectives reaches the optimum. $f_1^* \sim f_8^*$, and X^* is a ideal point.

$$F^* = (f_1^*, f_2^*, \ldots, f_8^*)^T$$

Applying the Fuzzy set theory, each objective function values at the ideal point is represented as the optimum membership function. The noninferior solution is

$$F_i = [\,\mu(f_{i1}),\ \mu(f_{i2}), \ldots,\ \mu(f_{i8})]^T$$

The noninferior solution of the closest ideal point F^* is the multiobjective optimum solution. The corresponding scheme is the multiobjective optimum scheme.

4 Membership Function

The objective function value of ideal point is taken as a optimum.

Definition 1: If the larger the objective function is , the better, the membership function of objective for excellent is defined by

$$\mu(f_{ij}) = \left[\frac{f_{ij} - \min(f_{ij})}{f_i^* - \min(f_{ij})}\right]^P \tag{4}$$

$$\min(f_{ij}) < f_{ij} < f_i^*$$

where i is a scheme numbering

j is a objective numbering

p is a index value and tests confirm that p is 0.8.

Definition 2: If the smaller the objective function is, the better, the membership function of objective for excellent is defined by

$$\mu_{(fij)} = \left[\frac{\max(f_{ij}) - f_{ij}}{\max(f_{ij}) - f_{i*}} \right]^p \quad (5)$$

$$f_{ij}^* < f_{ij} < \max(f_{ij})$$

where the symbols are idem.

5 Method of search

5.1 Search

F^* and F_i: are two Fuzzy subsets, $\mu(f_1^*)$ =I, the relative distance between F^* and F_i is $\delta(F^*, F_i)$

$$\delta(F^*, F_i^*) = \frac{1}{\sqrt{q}} \sqrt{\sum_{j=1}^{q} p_j \left[1 - \mu(f_{ij})\right]^2} \quad (6)$$

where p_i is the weight coefficient of the jth objective
q is the objective number
$\min \delta(F^*, F_i)$ is the optimum

It expresses the smallest distance between the corresponding scheme and the ideal point. The scheme is the multiobjective optimization scheme of environmental assessment about town planning.

5.2 Weight coefficient

P_j, the weight coefficient is defined by research.

P_j=*(0.17, 0.16, 0.11, 0.15, 0.09, 0.10, 0.15, 0.07)*

6 Summary

Practice indicates that it is feasible that the assurance conditions are taken as the restrained conditions to optimize multiobj ective, assess environmental influence, abolish the scheme being disadvantageous to environmental protection and chose the optimum scheme.

Transport environmental implications of buildings

N. P. Howard, A. Gilham, S. Rao and M. Thomas
The Building Research Establishment, Garston, Watford, UK

Abstract

This paper describes work conducted by Davis Langdon and Everest and BRE which led to the formation of the Transport Related Environmental Impacts from Buildings Project - TRIP, funded by the EC SAVE programme.

Environmental audits of British Council Headquarters offices in London and Manchester revealed the significance of transport energy compared to life cycle operational and embodied energy for the buildings. The transport energy and consequential emissions from 6 further offices were studied under sponsorship from the UK Department of the Environment. In particular, the benefits of comprehensive public transport in London and reducing the use of singly occupied cars for commuting are prominent.

These studies have not taken into account the local environmental impacts of noise, dust, vibration and subsidence damage, traffic congestion and visual impacts which are prominent in local planning policy.

The methodologies used for the transport assessments entailed self-completion staff questionnaire survey and data analysis. Operational energy results were obtained from energy bills over identical periods without (degree-day) normalisation for location. Life cycle embodied energy estimates were derived from a prototype estimator.

TRIP aims to produce 15 to 20 case studies of initiatives taken by organisations in the UK, France and Spain to reduce the transport related environmental impacts from their buildings. The range of initiatives found in the UK are outlined and include ones that; use IT and teleworking, adopt different working practices, move location, promote public transport, car sharing, cycling and walking. Preliminary results suggest that these can provide sound economic and welfare benefits as well as environmental ones and these features often provide a sound business case.

TRIP will also generate a series of benchmarks of transport energy and emissions from 30 buildings studied at the pilot stage to identify the most promising cases studies. The case studies will present these in the context of the buildings and organisations studied.

Keywords: Transport, Environment, Buildings, Energy

1. Introduction

This paper describes the work conducted by Davis Langdon and Everest and BRE which led to the formulation of the Transport Related Environmental Impacts from Buildings Project - TRIP, funded by the EC SAVE programme. This stemmed from an environmental audit of the British Council's Headquarters offices in London and Manchester in accordance with the Council's corporate environmental policy. Initially, it was sponsored by the British Council and then extended under sponsorship from the UK Department of the Environment.

The paper then outlines some preliminary findings from TRIP which aims to produce 15 to 20 case studies of initiatives taken by organisations in the UK, France and Spain to reduce the transport related environmental impacts from their buildings. It illustrates the range of initiatives that have been found and suggests that these can provide sound economic and welfare benefits as well as direct environmental ones. In this respect, the benefits span the range of issues implied by "Managing for Sustainability".

Personal transport accounts for 22% of national energy consumption in the UK. A large proportion of this is used for commuting. Overall, emissions due to personal transport are growing at 4% per year.

2. Origins of TRIP

2 1 British Council Headquarters Offices

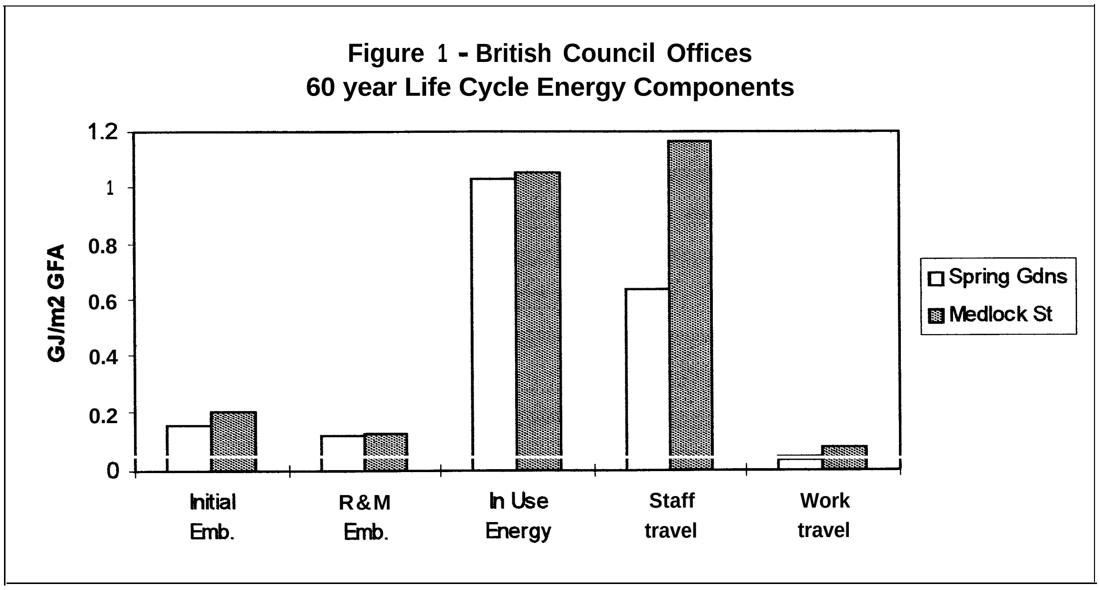
In 1994, the British Council launched a corporate environmental policy and strategy that placed emphasis on reducing the impacts arising from its buildings. Davis Langdon and Everest Energy and Environment Group were contracted to perform an environmental audit using BREAM 4/93 for existing offices. In addition, the Council wished to go beyond BREEAM in establishing the starting point from which they could monitor improvements in environmental performance. The emphasis of this work was on the Councils portfolio of property and how it was being utilised and not just the buildings in isolation. Hence, the Council were keen to explore the implications of repair and maintenance and transport and location.

The Council wished to start by investigating its two large headquarters buildings, one in Spring Gardens in the centre of London and the second at Medlock Street in Manchester. The London office is a 1970s prestige air-conditioned building in the heart of London between Trafalgar Square and the Mall. It is well served by public transport and has no car parking provision even for the most senior staff. The Manchester office was a late 1980s atrium building near to the centre of Manchester, built on a former contaminated land site. Although the site was reasonablly well served by public transport, much of the site had been capped with concrete and turned into car parking.

The repair and maintenance issues were investigated in terms of embodied energy for the buildings when built and then subsequently for their repair and maintenance over the assumed 60 year lives for the two buildings. The Council and their contractors had kept meticulous records, which facilitated the analysis.

The transport implications were investigated by means of a simple self-completion questionnaire survey for staff at the two offices. To encourage a good response, this was combined with a competition to win several bottles of champagne. The results were collected in just one day at each office. At both offices, a 10% response rate was achieved. This is a typical rate of response to self-completion surveys which are not chased. However, since only 50% of Council staff are typically in the office on any one day, there was, in effect, a 20% response rate by staff present, which is generally considered to be good. In all, 73 questionnaires were received from the London office and 56 from the Manchester office.

Figure 1 shows all of the results on a common scale of GJ/m^2 of floorspace for the two offices. The energy consumption is presented in delivered energy terms throughout.

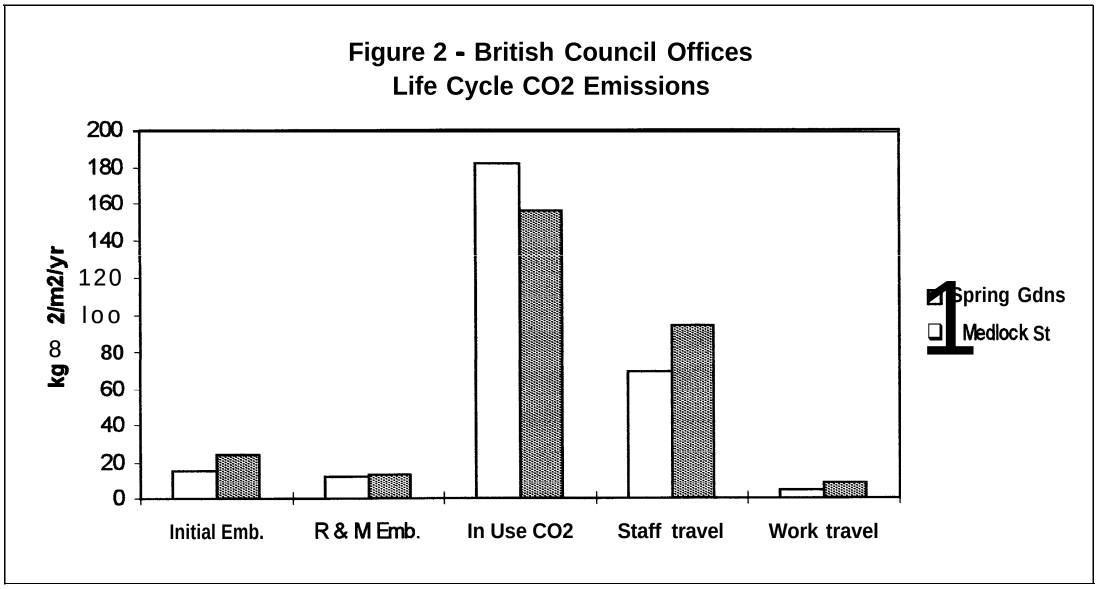


The results show that the embodied energy components for the two offices are similar, and relatively small compared with those for operational energy (heating, cooling, ventilation, lighting, power, catering etc.). The energy attributable to maintenance was particularly low (it can often be double these levels), a testament to the diligence of the Council in its maintenance procedures.

The operational energy consumption for the two buildings was almost the same. (Densities of occupancy were also similar hence the results are similar if expressed per occupant).

The most marked difference was that due to the energy used in commuter transport. Although staff in the London office typically travelled longer distances, their energy consumption overall was half that of commuters to the Manchester office. Scrutiny of the results confirmed that the crucial difference was the proportion of commuters travelling in cars with just one occupant.

Figure 2 shows the results expressed in terms of CO_2 emissions. Although similar in trend, the differences are smaller. This is because public transport in London consumes a greater proportion of grid electricity mostly from coal fired power stations (although the proportion is declining in favour of gas and other sources).



These results were considered to be highly significant because, at the time, benefits were being claimed for relocation outside of city centres with their associated pollution. Savings in energy consumption were anticipated avoiding or minimising the use of air conditioning. These results, however, reveal that this strategy can well result in extensive use of private cars for commuting. If, these cars are mostly singly occupied then net increases in life cycle energy consumption are likely.

2 2 Other Offices

In order to check that these results were representative, a further 2 British Council offices and 4 Davis Langdon & Everest (DL&E) offices were investigated using the same technique, but focusing only on the commuter transport issue. British Council Regional offices at Cardiff and Edinburgh and DL&E offices at London, Manchester, Cambridge and Liverpool were investigated.

Figure 3 shows the energy consumed in commuting for all eight buildings, together with the proportion of car transporation. Figure 4 shows the equivalent average transport distances for those responding to the questionnaires.
